A. The amount of infection entering such supply so far as this can be determined by reference to the population, urban and rural, draining into such supply, together with the conditions as to the probable disinfection of discharges from the bodies of patients; the freshness of such infection as indicated by the nearness of the source of infection to the point where the water supply is obtained; the analytical data, chemical 10222 and bacteriological. All these elements enter into consideration in passing judgment on the quality of a given water

Q. Is there anything in sanitary science that permits or has established an exact, definite and distinct formula, so far as time limit is concerned, from the source of the deposit of the infected material in the water of the stream that is being analyzed or examined?

A. I know of no such formula nor do I believe that it would be wise or feasible in the present state of sanitary science to attempt to advance such a formula inasmuch as a problem of this sort contains certain individual elements which compel it to be considered as an individual case.

Q. The life limit of the disease producing organisms discharged into a running stream or a water supply depend, do they not, upon the character of the organism, the temperature of the atmosphere or water as well as the volume of water?

A. The character of the specific microbe and the temperature of the water would certainly have some influence upon the period of longevity. I am not quite clear as to what is meant by the volume of water in this connection. If a single discharge from the body of a typhoid fever patient was mingled with 1,000 gallons or 10,000 gallons of ordinary city sewage, I do not see how the longevity of typhoid bacilli contained in said discharge could be materially influenced by the volume of the sewage in which it was placed.

10223 Q. I gathered from your direct examination, Professor, that a certain amount of typhoid infected material would survive longer if discharged into a large body of water than if discharged into a small body of water. Am I correct?

A. I think I made the statement that if a given quantity of typhoid infected material were discharged into a body of pure water the bacilli would, in my opinion, live longer in that pure water than if they were discharged into a body of water highly polluted with sewage.

Q. By the use of the term "pure water" in your last answer, do you mean distilled water?

A. I understood the question to refer to a natural body of water and answered it with that understanding.

Q. What is the relation between the chemical operation going on in the purification of water and the bacterial operation that is going on in the purification of water, Professor?

A. The term "purification of water" may be and often is used with reference to distinct processes. What is commonly meant by the chemical purification of a polluted water is the oxidation and nitrification of the organic compounds contained in such water. The phrase "purification of water" may also be used to express the disappearance of pathogenic bac-
10224 teria that may have been introduced into it. In a general way it is found that the processes of chemical and bacterial purification run a parallel course.

Q. Do sanitarians regard that water as safe for domestic purposes which gives unsatisfactory results when examined chemically but fails to disclose unsatisfactory results when examined bacterially, so far as bacterial counts are concerned?

A. There are conceivable and indeed actual cases when light may be shed on the sanitary quality of a water by the chemical examination, when the bacterial count, at the time the examination is made, fails to shed much light. For example, the water of some wells is often found to be high in nitrates and chlorine, under conditions that indicates that such chlorine and nitrates originally proceeded from sewage pollution. The number of bacteria in such well water may be low at the time the examination is made, but owing to the dangerous character of the surroundings of such a well, as indicated by the nitrates and chlorine, such water would be condemned by the prudent sanitarian although the bacterial count was not high. The reason for this is that such a well water showed a bad history. It had been seriously polluted in the past but the pollution had passed away as shown by the bacterial count and the high nitrates. Such a water might be, however, at any time liable
10225 to another influx of pollution and so should be condemned
on the basis of the information revealed by the chemical analysis, although the bacterial count might be so low as to show at the time of the examination it was innocuous.

Q. Is it not a fact that all your chemical analysis of the waters of the Illinois River, the Desplaines River and the drainage canal has indicated bad ancestry of that water?

A. The analysis of the drainage canal and of the Desplaines River, below Lockport, certainly indicates undesirable water. The analysis of the Illinois River water shows in my opinion that the water has not had an unimpeachable sanitary history. The water of the Illinois River at its mouth above Grafton shows, by its chemical constituents, that it has at some point or points along its course, received a large amount of sewage. The condition of such a water as that of the Illinois River at its mouth is, however, very different from that of the well water that I have just mentioned. In forming any judgment as to the character of the Illinois River at its mouth there ought always to be taken into consideration the sources of pollution on the entire water shed of the Illinois River from its source to its mouth.

10226 Q. And in considering whether or not the water in the Illinois River, at its mouth, as shown by the chemical analysis of it is free from pathogenic germs or substances, the sanitarian must take into consideration the question as to whether or not the natural facilities for purification and time limit for death of such pathogenic germs has occurred before reaching the point in question, must he not?

A. It is very difficult, as I have already pointed out, to reason from chemical changes taking place in a flowing stream to the death of pathogenic bacteria in such a stream. We simply know that in general the processes of nitrification and the death of pathogenic bacteria run a parallel course. In other words both require time for their accomplishment. The exact time relations in each case are, however, a matter for experiment. Such factors as temperature, concentration of organic matter, the intervention of algae or other higher forms of life may play a part in influencing either process. In a river like the Illinois, the process of nitrification is a very complicated one. The oxidation of organic nitrogenous compounds to nitrates may be interrupted by the agency of green algae or by the introduction into the stream at various points along its course of fresh organic matter.

Q. Of what particular value then do you consider the
10227 chemical analysis of the water in a running stream in passing judgment upon the sanitary condition of that water?

A. When examinations of a stream are made at several points along its course at different seasons of the year, and with due regard to the introduction of fresh organic matter, such examinations show that a considerable time has elapsed since the introduction of sewage which might presumably have contained pathogenic bacteria. The art of chemical water analysis as I understand it, is based upon experience. Analysis made by many investigators in different parts of the world have shown that waters in which the process of nitrification is far advanced are not so liable to cause disease as waters containing the unstable nitrogenous compounds. It is purely in this empirical way that chemical water analysis is valuable and sheds light upon the sanitary character of a water.

Q. Professor, based upon table 134, introduced by yourself, being a part of the several tables known as Streams examination Chicago Sanitary District, wherein 26 samples of water were analyzed from the 2nd day of January, 1900, to the 26th day of June, 1900, the samples being analyzed weekly, the average chemical constituents for the 26 samples being as follows:

Residue on Evaporation, total 303.1.
Residue on evaporation, suspended, 55.5,
10228 Residue on evaporation, dissolved, 247.6,
Chlorine 13.55,
Oxygen consumed, total, 8.1,
Oxygen consumed by dissolved, 6.6,
By suspended matter, 1.5,
Free Ammonia, .815,
Albuminoid ammonia, total .366,
Dissolved .226,
Suspended .114,
Nitrogen as nitrates .064,
As nitrites 1.15,

Bacterial counts 51,834, the maximum and minimum chemican constituents and bacterial counts of these samples being as follows:

Residue on evaporation, the total,
Minimum 210, Maximum 486,
Dissolved, minimum 132, maximum 358,
Suspended, minimum 0, maximum 304,
Chlorine, minimum 7, maximum 49,
Oxygen consumed, total,
Minimum 5.8, maximum 17.2,
Dissolved, minimum 5, maximum 8,
10229 By suspended matter,
Minimum 0, maximum 10,
Free ammonia, minimum .12, maximum 2.56,
Albuminoid ammonia, total,
Minimum 2.56, maximum 7.36,
Dissolved, minimum .12, maximum .384,
Suspended, minimum .008, maximum .464,
Nitrogen, as nitrates,
Minimum .01, maximum .24,

As nitrites,
Minimum 0, maximum 3.4,
Bacterial counts,
Minimum 800, maximum 210,000.

Knowing that the sewage from about 1,600,0000 people living in the City of Chicago is discharged into the drainage canal thence into the Desplaines and Illinois Rivers, and passes the point on the river known as Averyville, 155 miles from Chicage, the same being the point at which the samples of water in question were taken, I will ask you if in your opinion the water at that point has become freed from the effect of said sewage upon it, as shown by the results of the above an-
10230 alysis?

A. The large amount of chlorine present in the Chicago sewage as in all sewage makes itself evident in the waters of the Illinois River at Averyville, as shown by the analysis cited. So too does in my opinion the large amount of nitrogen introduced in the sewage of Chicago. It is difficult to see how this could be otherwise. The chlorine is in the form of a stable, mineralized compound, common salt, and suffers little if any diminution in the total amount in its passage down the river. The nitrogenous compounds of various kinds are altered more or less in their passage down stream, and the amount of nitrogen appearing under different heads varies from point to point, and some of that oringinally introduced into the stream disappears. There is, however, a large amount of nitrogen in the form of its various compounds, free ammonia, albuminoid ammonia, nitrates and nitrites, in the waters of the Illinois at Averyville which has in my opinion come in a more or less changed condition from Chicago.

Q. What is true with reference to the chemical condition of the water in the Illinois River as shown by table number 134, just referred to, so far as the respective chemical substances are concerned is also true with reference to all other tables introduced by you, containing the chemical analysis of the
10231 waters of the Illinois River is it not?

A. That some effect exists due to the introduction of Chicago sewage, yes sir.

Q. What I have reference to, Professor, is that these various chemical constituents make their appearance in the chemical analysis at the various points on the river where the samples of water are taken, which are afterwards analyzed, and show preceding discharges of polluting material into the river above the points where the samples of water were taken?

A. Yes sir.

Q. Speaking from the science of chemistry alone, as you understand it, can you state that your chemical analysis of the water of the Illinois River at any point is free from disease producing substances, and if not can you as a chemist state with any degree of certainty the exact source of such substances?

A. I can only say that in the light of all the experience that I have had in the chemical examination of water, and all the information that I have derived from a study of the work, of other investigators, the amount and rate of nitrification in the waters of the Illinois River, from Lockport to Grafton, are such as have been found in the experience of water analysts to 10232 accompany the disappearance of disease producing elements.

Answering your question directly I will say that I do not believe it is possible to affirm absolutely from the results of the chemical examinations alone that the water of the Illinois River at any point where I have taken samples and made analysis is free from disease producing elements.

Furthermore, assuming that such disease elements are present in the water of the Illinois River at Grafton, I do not see how it is possible to affirm, on the basis of chemical analysis alone, whether these disease producing elements were derived from Peoria, from Havana, or from some farm house situated two or three miles above the points where the samples were taken. The whole question of chemical water analysis, as I have reiterated, is simply one of deduction made on the basis of past experience. A chemical examination does not disclose the existence or presence of the different disease producing elements in the water. It simply affords a certain kind of evidence that must be weighed in forming a judgment as to the sanitary quality of the water.

Q. Professor in all of the chemical tables or all of the

10233 tables of chemical analyses which you have introduced in evidence, did you perform the work personally yourself?

A. I did not. The work was done by one of my assistants, Dr. Stevens.

Q. And under your superivision?

A. Yes sir.

Q. State whether or not in your opinion, Professor, the chemical analyses so introduced by you are accurate in every respect?

A. The methods used in chemical water analysis are liable to certain sources of error, depending upon the experience of the observer and other factors inherent in the methods themselves so that the results have chiefly a value for purposes of comparison.

Q. What is the percentage of inaccuracy allowed by you in each of the determinations made by you?

A. In the case of the residue on evaporation where the determination is properly performed the limits of error ought not to be more than two per cent. in the hands of an experienced investigator.

In the case of chlorine, where allowance is made for volume, the error perhaps would be 5 or 10 per cent.

The oxygen consumed, the error may be as much as 15 per cent.

10234 The tables of free and albuminoid ammonia ought to be accurate within about 5 per cent.

The nitrite determination is very delicate and the error here may be considerable. Unless strict laboratory precautions are used, the error may be as much as 10 or 15 per cent.

The method for determining nitrates I do not regardl as accurate within 20 or 25 per cent.

Q. Do you know whether the methods that were used by Professor Palmer were the same as those used by you in making the chemical analyses of the water?

A. In general they were the same. Professor Pallmer, I believe made no correction for volume in his chlorine determinations which would make his chlorine results somewhat higher. In general the methods were the same.

Q. State, Professor, whether the samples of water examined by you chemically and also by Profesor Palmer taken at the same time and in the same places should show practically the same result?

A. I do not think that they should for the reason that the time consumed in transporting the samples to the University of Illinois laboratory at Champaign and to the University of Chicago laboratory where the work under my supervision was done, was quite different for different samples of water. The residue on evaporation and chlorine ought to be substan-
10235 tially the same. Errors of analysis would sometimes occur in spite of all precautions. The nitrogenous compounds and the oxygen consumed may show considerable variation owing to the changes taking place during transportation.

Q. And in these nitrogenous compounds you include nitrites and nitrates?

A. I certainly do. Those are compounds that are very liable to change during transportation.

Q. Then the large quantities of nitrites and nitrates appearing in the analyses made under certain conditions may be the result of the delay in transportation and in the delay in analysis after the samples were taken?

A. That may in part account for the conditions observed as regards the nitrites and nitrates but the methods used for the determination of nitrates may also account for some of the conditions observed.

Q. There would be a considerable change would there not in the nitrates and nitrites?

A. There might.

Q. In what way would that change manifest itself?

10236 A. The nitrates might diminish and the nitrites increase in some water or both nitrates and nitrites might diminish owing to the reduction of these contents in the presence of organic matter. Suppose that living algae were taken in a bottle of water and died during transportation, the bacteria present in the waters would flourish upon the nitrogenous matters contained in the body of these algae and in so doing would reduce the nitrates and nitrites and might cause the marked diminution or even disappearance of these compounds.

Q. In the event that the nitrites or nitrates should be in creased or either of them increased from what particular chemical substances would they be drawn?

A. The increase in the amount of nitrates would come from the oxidation of the nitrites.

The increase in the amount of nitrites might come from the oxidation of free ammonia or it might come from the reduction of nitrates.

Q. I notice, Professor, in comparing your results of your analyses made by yourself and Professor Palmer from the water taken at Kampsville January 17, 1900, you find 1.15 nitrates, Professor Palmer finds 2.60 nitrates. Those samples were taken at the same place by the same sample taker. Your analysis 10237 was made on the 19th and Professor Palmer's was made on the 18th the analyses, however, showing a difference of 126 per cent. based upon your analyses as 100 per cent. What do you say as to this variation?

A. This variation may be an analyst's error or it may be due to the method employed for the estimation of nitrates which did not prove altogether a satisfactory one. It may be due possibly to a reduction of nitrates in the samples of water sent to my laboratory owing to the longer period elapsing after collection and before examination was made. I have already mentioned the fact that such reduction of nitrates does sometimes occur. It is my opinion that such a discrepancy as that to which you call my attention did not exist in the original samples of water but that some other explanation must be found.

Q. Have you any other reason to believe that Professor Palmer's analyses of determinations of the nitrates as contained in that sample better represented the actual condition of the water in the river at that point at that time than does your own analysis?

A. I have no means of knowing which of these two figures more correctly represents the original condition of this water.

Q. Professor, comparing your analyses with those of Pro- 10238 fessor Palmer made from water taken from the Illinois River at Kampsville, the samples of water being taken, as shown by the testimony, by the same water taker and shipped to the respective laboratories in the manner described in your testimony I find the result of determination of nitrates of the following samples to be as follows:

Sample taken January 25, analyzed by both you and Professor Palmer on the 26th, in which you found 1.1 nitrates and Professor Palmer found 2.0 nitrates. The sample taken January 31st, examined by you on the 2nd day of February, and by Professor Palmer on the first day of February, you found 1.7 nitrates, and Professor Palmer found 1.8 nitrates. The sample taken February 7th, examined by each of you February 8th in which you found .25 nitrates and Professor Palmer found 1.84 nitrates. The sample collected February 14th and examined by each on the 15th, you found .55 nitrates and Professor Palmer found 1.72 nitrates. The sample collected February 21st, examined by you on the 22nd and by Professor Palmer on the 23rd you found .6 nitrates and Professor found 3.0 nitrates and in these respective determinations in a sample collected on the 25th day of January the variation between the two determination was 81.9 per cent, the variation in the sample taken January 31 was .59 per cent., the variation in the sample taken February 7th is 635 per cent., the variation in the sample 10239 taken February 14th is 213 per cent., the variation in sample taken February 21st was 234 per cent., based upon your figures as 100 per cent. In each instance Professor Palmer found a greater quantity of nitrates than yourself. I will ask you if there is any reason to believe that your determinations represent more actually the condition of the water in the Illinois river at Kampsville, at the time the samples were taken as far as the chemical constituent known as nitrates are concerned, than does the chemical determinations of Professor Palmer for that chemical constituent?

A. On the contrary I should say on examining these results critically that Professor Palmer's examination possibly represent the original condition of the water as regards the nitrates contained more nearly than my own, for the reason that samples of water collected at Kampsville could reach the laboratory of the University of Illinois at Champaign in a shorter time than they could reach the laboratory of the University of Chicago. In the latter case time for reduction of the nitrates would be afforded. Especially if the bottles of water were allowed toremain in warm express offices instead of in a refrigerator in the laboratory. It is true of most of the samples from the lower part of the Illinois river that the time consumed in transportation to Chicago was greater than that consumed in the transportation to Champaign, and changes taking place might be assumed to be greater. This is a possibie explanation of the lower nitrates at Kampsville in the determinations made in my laboratory as compared with the nitrate examinations made in Professor Palmer's laboratory in the University of Illinois. 10240

Q. Is it your opinion that the chemical constituents known as nitrates would make such a radical change from the point of collection to the point of analysis within the time which this examination was made?

A. Such a change might take place within 24 hours under certain conditions.

Q. How do you acount for the variation in such large percentages in those samples that were collected upon the same day and anayzed by each of you upon the same day, especially referring to samples collected on the 25th of January, the 7th of February and the 14th of February?

A. I have already indicated a possible explanation for the low nitrates observed in the determinations made in my laboratory, namely, the changes that takes place after the collection of a sample and before the determination is made.

Q. I notice, Professor, a variation of 42 per cent. in the dissolved residue in the samples collected on the 17th of January, 1900, as shown by the analyses made by yourself and Professor Palmer, his being 42.3 per cent. greater than your own, basing your work at 100 per cent. I will ask you if you can acount in any way for this variation? 10241

A. I can not. Any one who has had experience in water analysis, knows that differences in collection, in transportation and errors in the process of analysis sometimes occur where a large number ot samples are examined in spite of all efforts to obtain uniform and strictly comparable results. Whether this difference to which you call my attention was due wholly or in part to an error during process of analysis I am unable to state.

Q. Should there be any marked difference in the determination of chlorine results?

A. This determination depends upon the reading of color by the different observers. They vary somewhat in their accuracy in making this determination.

Q. I notice in the sample of water collected on the 21st day of February, 1900, a variation in the determinations made for the chemical constituent known as chlorine by yourself and Professor Palmer of 41.5 per cent. Is this an average or an abnormal variation?

A. That is a variation larger than I should expect to occur without some error on the part of someone engaged in the analytical work.

Q. Do you attribute that variation to a difference in the
10242 chemical condition of the water at the time and in the
place where the two samples were taken?

A. It may be due in part to either circumstance. I should personally be inclined to attribute it to the analysis itself.

Q. Is it not a fact, Professor, that the determinations made chemically are of such a delicate character that the exact chemical condition of any water can not be absolutely determined?

A. Referring your question to the determinations usually made in sanitary water analysis—

Q. I intended to put that in.

A. I would say that it is certainly a fact that those determinations are so delicate that even experienced water analysts obtaining samples of water under the conditions in which these samples were collected would be expected to arrive at results that would differ in some cases. These results might differ considerably, as you have shown that the results obtained by Professor Palmer and myself do differ. Regarding the sanitary significance to be attached to such variations, however, is a different matter. Variations of 50 or 100 per cent. in certain constituents of certain waters would have no sanitary importance
whatever. The averages of a considerable series of anal-
10243 yses are more important from the sanitary point of view
than any single analysis and this fact is so generally recognized by water analysts that little weight is attached to a single determination.

ADJOURNED until 10:00 a. m., February 13, 1904.

10244 10:00 A. M., Saturday, February 13, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same Counsel representing the respective parties, also C. D. Corum representing complainant.

PROF. EDWIN O. JORDAN,

resumed the stand for further cross examination by Mr. Jeffries, and testified as follows:

Q. Is it not true that the results of various competent observers differ greatly as to the longevity of the cholera spirillum in natural water?

A. The reported experiments on this matter relate, so far as I am aware, to the life of the cholera spirillum in glass bottles in the laboratory and vary with respect to number of germs introduced, to freshness of isolation and in other respects.

I think it would be anticipated on bacteriological grounds that experiments conducted under these conditions would show considerable variation in the outcome.

Q. It is true then is it that there is a great difference in the results as determined by various competent observers?

A. In these laboratory experiments conducted under different conditions, yes sir.

Q. Do you know of any experiments conducted in any other way for the purpose of determining the longevity of the cholera germ?

10245 A. Experiments in aquaria have been made to simulate natural conditions. I have already referred to the outcome of these experiments in my testimony.

Q. Is it not a fact, Professor, that competent observers have found it to live after 7, 15, or 20 days, or even three months or longer?

A. I am familiar with the experiments to which your question refers, and I would state that in my opinion the conclusions drawn as to the life of the cholera spirillum in such waters under such conditions are by no means valid, for the reason that in the experiments referred to in your question the agglutination test for the identification of the cholera spirillum was not performed, and it has been shown recently that organisms exist in water, especially in polluted water, which simulate the cholera germ very closely in their bacteriological characteristics and which can be distinguished from it only by the application of this agglutination test. Unless this agglutination test be employed we are unable to attach any weight whatever to reported findings of cholera spirillum in waters after the lapse of long periods.

Q. Then you disregard and attach no credit to the determinations made by such observers?

A. In the light of recent discoveries I am compelled to accept the position as stated. The agglutination test is now
10246 recognized by bacteriologists as essential to the identification of these organisms and within the last few months an important paper has been published in the Zeitschrift fur Hygiene, from one of the leading German Laboratories, in which it is shown that organisms formerly classed as cholera microbes, and preserved in various bacteriological laboratories are not cholera germs at all. It seems possible that some of the experiments to which you refer were conducted not with the genuine cholera germ but with some of these sewage bacteria which there is every reason to anticipate would have a greater longevity than the cholera germ itself.

Furthermore, the isolation of a spirillum from a polluted water into which cholera spirilla had been introduced would have little or no significance unless the agglutination test were applied.

Q. Professor, is it not a fact that competent analysts and observers have found the cholera germ able to live in sewage as long as from seven to thirteen days?

A. I have already indicated very clearly my answer to that question in the two preceding answers. I do not believe that it has been so demonstrated.

Q. And your reason for so believing is as stated in your preceding answer?

A. My reasons are as stated.

Q. What in your judgment did you say was the life limit
10247 of the cholera spirillum in ordinary river water?

A. I have no experimental data bearing on the question of the longevity of the cholera spirillum, under truly natural conditions, nor so far as I am aware do such data exist.

Q. So then in your judgment that question has never been answered by sanitary science?

A. The question as to the specific longevity of a true cholera spirillum under natural conditions, no sir.

Q. Professor, are bacteriologists in close agreement as to the longevity of the typhoid bacillus, under various conditions?

A. As I have stated in my answer to a similar question concerning the life of the cholera spirillum, the laboratory experiments that have been conducted in glass vessels have been under such varying conditions of temperature, age of typhoid culture employed, the nature of the water into which such a bacterium was introduced, and other experimental factors that it would be anticipated that the results would show some variation. The experiments that I have introduced in my testimony, which were made with as close an approximation as possible to natural conditions, have given, in my opinion, singularly concordant results, using different strains of typhoid bacilli, different numbers in a given quantity of water, and otherwise attempting to simulate conditions occurring in natural infection.

10248 Q. It is a fact then is it not that they differ widely as to the number of days during which typhoid bacilli may live in water and in sewage?

A. If you refer to these experiments that have been conducted during the last 15 or 20 years by different bacteriologists using different methods, and at different periods in the state of the science, and working under laboratory conditions varying very widely in fundamental and important particulars, it is of course true that the life of the typhoid bacillus has been reported to vary widely. I have myself found that in sterilized water taken from Lake Michigan a freshly isolated culture will live for 93 days, but that a freshly isolated typhoid culture introduced into ordinary sewage under natural conditions, lives but two days.

Q. It is an agreed fact among bacteriologists and sanitarians that typhoid fever germs live in water and in sewage is it not, after such germs have been discharged into such sewage or water?

A. It is, I think, generally conceded that some typhoid bacilli may retain their virulence, after reaching the water or sewage, just as some typhoid bacilli introduced into an antiseptic solution remain alive for a certain period and do not die instantly.

Q. Is it not a fact that a sufficient number of typhoid bacilli when discharged into a water supply by means of the sewers of a city or otherwise do create typhoid epidemics among the people who use that water supply for domestic and drinking purposes?

10249 A. In my opinion the epidemiological evidence that water can be a vehicle for conveying typhoid infection is overwhelming, as I have repeatedly stated in my testimony.

Q. Now, while scientists agree that typhoid fever germs when discharged into a running stream or water supply live and remain virulent in sufficient quantities to produce typhoid epidemics, is it not also generally understood by such scientists that the life of the typhoid germ depends for its duration upon the character of the water into which it is discharged, the natural conditions which surround it and the temperature of the water?

A. I think it is generally conceded that the character of a body of water into which a typhoid bacillus is discharged influences the period of longevity of such bacillus.

Q. May not the conditions in a water supply, such as a running stream, be of such changeable character as to permit at various times the interchangeable shortening and lengthening of typhoid germs which are being discharged into the water?

A. As I have indicated in my previous answers changes in the character of a water may influence within limits the longevity of a typhoid bacillus introduced into it.

Q. What limits do you have reference to, Professor?

A. It is my opinion that from such changes as might ordinarily be expected to occur in a natural body of water that
10250 the life of the typhoid bacillus would not be indefinitely prolonged by such changes. Under the favorable conditions existing in laboratory experiments when the typhoid bacillus is introduced into sterile water in glass bottles it has

been shown that the typhoid bacillus perishes after a short period. In natural waters a similar termination would undoubtedly occur even under the most favorable conditions that would exist in nature.

There is no evidence, bacteriological or epidemiologically that indicates that the typhoid bacillus multiplies in natural waters, but on the contrary all the available evidence shows that from the moment of introduction a diminution in the number of typhoid bacilli takes place. In other words, I do not believe that in natural waters the life of the typhoid bacillus can be indefinitely extended.

Q. What effect has the added volume of water from Lake Michigan upon the typhoid fever germs discharged from the sewers of Chicago as it passes through the Chicago River and the Drainage canal, as applied to the conditions and surroundings of those germs while contained in the sewage proper?

A. I have made no experiments upon the life of the typhoid bacillus in sewage taken directly from the city sewers of Chicago as compared with the life of the same bacillus in such sewage diluted 20 times with Lake Michigan water. I have, however, made some experiments upon the diminution in the number of colon bacilli in ordinary undiluted sewage and
10251 in sewage diluted 1 to 20 with Lake Michigan water,
and I find no difference in the rate of dying off of the colon bacillus in these two fluids, namely raw ordinary sewage and sewage diluted 1 to 20 with the waters of Lake Michigan.

It is conceivable that the life of the typhoid bacillus may be prolonged for a few hours if introduced into a less concentrated medium, owing to a difference in the intensity of the action of the toxic products, but I do not believe that such influences would extend the life of the bacillus more than a few hours.

Q. In expressing the above opinion you do so without having made a personal observation or analysis of the water under the two respective conditions do you not?

A. I have determined, as heretofore related in my testimony, the longevity of the typhoid bacillus in the sewage of the drainage canal. This longevity is so brief that, assuming that the bacillus dies out in concentrated sewage in less than two days, the difference can hardly be more than a few hours. The behavior of colon bacilli in concentrated and diluted sewage has also influenced me in forming the opinion that I have just expressed.

Q. The opinion which you stated with reference to the longevity of the typhoid germ in the drainage canal was fixed at a limit of 2 days was it not?

A. In the experiments that I have recorded in my tes-
10252 timony I did not find typhoid bacilli later than 2 days,
even when enormous numbers were introduced into the sewage, numbers much larger than would be at all likely to exist in the drainage canal under natural conditions.

Q. Assuming, Professor, that the sewage of Chicago be discharged into the drainage canal, as now, and that the water and sewage passes down the canal for a period of two days, at which point it is discharged into a reservoir from which a community obtains its water supply, would you consider that water as being free from typhoid fever germs, assuming also that there is an average rate of from 700 to 1000 deaths from typhoid fever in the City of Chicago per annum?

A. I should not wish to put myself in the position of recommending the introduction of sewage of any degree of staleness into a reservoir from which a public water supply was immediately taken out. The sanitary question is not the only one to be considered in such a connection. The aesthetic side is also worthy to be taken into account.

In discussing the results of my experiments performed in the drainage canal I have already stated that I should not as a sanitarian be willing to place two days as the utmost limit of longevity of typhoid bacillus in such water although this was the extreme limit found in a considerable number of carefully conducted experiments. This time ought at least to
10253 be doubled and possibly trebled in order to insure safety.

So far as the introduction of sewage contained in the Chicago drainage canal is concerned, provided such sewage were from 4 to 6 days old, it is my firm opinion based on the experiments that I have made and all the information, epidemiologically and otherwise that I have been able to obtain that typhoid bacilli would not be alive in such sewage.

I should like to relate in this connection an incident connected with my work at the Lawrence Experiment Station in Massachusetts. Among the experiments conducted there, were some experiments upon the filtration of city sewage through beds of sand. From one of the tanks used in these experiments an effluent was obtained which, chemically and bacterially, was very pure, although it had passed through only 5 feet of sand and was in point of time less than 5 days removed from the original sewage.

The analytical results, chemical and bacterial, obtained upon this effluent were so convincing that a number of those engaged in the experiments at the Lawrence Experiment Station at that time, including Professor Sedgwick, Mr. Hazen and myself, drank of this effluent and suffered no ill effect.

The results of the experiments that have been made by
Professors Russel, Zeit and myself are, in my opinion,
10254 as convincing as those obtained in the Lawrence Experiment, and in my opinion such sewage, under the conditions described, that had been infected 6 days before would be free from typhoid bacilli.

Q. Assuming, Professor, that the canal mentioned in the preceding question was of sufficient length to permit a flow of 6 days, and the other facts being as assumed in the preceding question, would you consider the water as being free from typhoid fever germs?

A. I should not hesitate to consider it as being free from typhoid bacilli.

Q. Professor, have you made any investigations as to the longevity of a typhoid fever germ in the waters of the Illinois River at Averyville?

A. I have not personally made such investigations, but I know of examinations made by Professor Russell in connection with the experiment that has already been described.

Q. That experiment was made in the same manner in which you made your experiments?

A. In substantially the same manner, I believe.

Q. Do you know, Professor, whether typhoid fever bacilli are influenced in death rate more rapidly by the toxin created by themselves or by the toxin created by other forms of bacteria?

A. Those substances that are spoken of in a general way
10255 as toxins have not been isolated as definite chemical
bodies and studied as such.

It is, therefore, difficult to answer your question which, as I understand it, is as to whether the products of the growth of typhoid bacilli are not more detrimental to typhoid bacilli than the products of growth of other micro organisms. The question is one which would have to be investigated with pure cultures and carefully controlled laboratory conditions, and there would be certain experimental difficulties. I know of no data directly bearing on your question.

Q. Do typhoid fever germs create toxin while in an unnatural state?

A. Understanding you to mean by unnatural state the conditions that prevail when typhoid bacilli are confined in glass vessels or other receptacles outside of the animal body, I would say that the meaning of the question, as I understand it, is not altogether clear. I am not sure whether you refer to substances that are poisonous for man or substances that are poisonous for other bacteria or substances that are poisonous for the typhoid bacillus itself.

Q. Are toxins thrown off by typhoid bacilli at any other time than when they are in course of growth and multiplication?

10256 A. Assuming that by your question is meant the formation of any chemical substance, poisonous to any living organism including in this the typhoid bacillus itself and other bacteria, I would say that the cells of practically all bacteria contain within themselves substances, chemical compounds, that are injurious to certain other organisms and there is no reason to suppose that the typhoid bacillus is peculiar in this respect. The disintegration of the cells of typhoid bacilli may give rise to substances in the immediate neighborhood of such disintegrating bacilli which are poisonous for various forms of organic life.

Q. Professor, do you understand the products of decomposing and disintegrating typhoid bacilli to be the toxin usually and naturally thrown off by such bacilli?

A. Assuming that by this question you mean to ask whether the toxin liberated by the typhoid bacillus which is responsible for the peculiar symptoms and lesions of typhoid fever in man originates from dead and disintegrating bacilli rather than from living ones, I will say that I do not.

Q. State, Professor, whether or not typhoid fever germs throw off toxins of any character while contained in water other than the toxins created by disintegration and decomposition of the typhoid cells themselves?

10257 A. Assuming again that by toxin you mean toxic products, I will say that I do not know whether typhoid bacilli contained in water emit, during life, any product harmful to themselves or to other organisms. Nor do I know whether, if such be the case, such products emitted during life are different from those that may pass into water from the disintegrating and breaking up of the cells after death. I do not believe that any accurate information on these two points exists.

Q. I will ask you, Professor, if it is not a generally accepted truth that typhoid bacilli will perish more rapidly from the effects of the decomposing and disintegrating typhoid cells which immediately surround them than from the disintegrating and decomposition of other bacteria?

A. I certainly do not know that to be a generally accepted truth.

Q. May not that, in your opinion, be a fact?

A. I have no opinion to offer on that point. I know of no evidence enabling one to form an opinion one way or another.

Q. Reasoning from the analogy of nature, I will ask you, Professor, if it is not reasonable to believe that typhoid bacilli would perish more rapidly on account of being surrounded and buried in their own filth and the products and by products of its own decomposing matter more rapidly than surrounded by such products and by products and decomposing matter produced by bacilli of a different nature and character? 10258

A. I do not see how such a conclusion can possibly be drawn. For example, to take an instance from bacteriology. In a mixture of bacillus anthracis and bacillus pyocyaneus, the anthrax bacillus will die out much more readily than in a culture where anthrax bacilli are present alone. The products of bacillus pyocyaneus upon bacillus anthracis seems to be much more injurious than the products of bacillus anthracis upon itself.

I know of absolutely no ground for assuming or supposing that the products of one micro organism are more injurious to itself than the products of every other micro-organism are to that particular one.

Q. Professor, with reference to the special analysis which were made by yourself in connection with Professor Zeit and Professor Russell upon the longevity of the typhoid bacilli, I will ask you if these parchment sacks were suspended in the water to their full depth?

A. They were. The glass tube to which the parchment sack was attached alone projected above the water.

Q. How far above the water did the point of the glass tube project?

A. I should say on the average several inches.

Q. How large was this glass tube, that is the opening?

A. About two-thirds of an inch.

10259 Q. On table 1 introduced in evidence by you, Professor, when you testified with reference to those special examinations, was this water that was used taken from the drainage canal at Lockport and the experiment carried on at that particular point?

A. It was. The parchment sack was filled with sewage taken directly from the canal at Lockport and then suspended in the float and typhoid bacilli immediately introduced.

Q. When were these determinations made with reference to the initial colon count of sewage bacteria?

A. The sample was brought immediately to the laboratory and plated at once.

Q. And the determination for the sewage bacteria, the colon bacilli and the streptococcus was then and there made?

A. Yes sir.

Q. And those determinations represented the laboratory determinations of the quantitative amounts or numbers of the respective bacteria contained in that water?

A. Yes sir.

Q. I notice that this table, Professor, says that the approximate amount of typhoid bacilli was 12000 per cc. May that have been greater or less?

A. The number may have been anywhere between 11000 and 13000. The number was determined by plating from a suspension in proper dilution and counting exactly the number of typhoid colonies appearing on the plate. All bacteriologists recognize, however, that where such large numbers are dealt with the determination is an approximate one and not exact to the individual unit. 10260

Q. Now, in plating these samples of water from this parchment sac after it had been suspended in the canal for 12 days or more, is it not a fact that bacteria other than typhoid appeared in large numbers upon the plate?

A. Upon some of the plates, yes, sir. The special media used, however, suppress a very large proportion of the ordinary sewage bacteria while permitting the typhoid bacillus to grow. In some cases over 90 per cent. of the sewage bacteria are suppressed by these special media.

Q. Do not other forms present themselves with the same rapidity as the typhoid?

A. Certainly.

Q. Forms that resemble the typhoid?

A. In some cases, yes.

Q. How many plates did you use, Professor, on an average in making these respective determinations?

A. 2 or 3.

Q. Do you consider that a sufficient number?

A. A sufficient number for what?

Q. To determine the presence or non-presence of typhoid bacilli in these experiments? 10261

A. I am not altogether sure that I understand the question. The details are set forth in each case. Thus, in table 1, on the fifth day after infection 1 cc.. of the water which originally contained 110,000 ordinary bacteria and 12000 typhoid bacteria was examined. This cubic centimeter of water when plated in Drigalski medium developed only 86 colonies in all, it being remembered that there were at the outset approximately 12000. Eight out of the total number of 86 colonies which developed on this plate were selected as the only ones closely resembling typhoid colonies. These were studied in detail and none of them proved to be typhoid bacilli.

In this case, therefore, the presumption is very strong indeed that out of the 12000 typhoid bacilli originally present in that cubic centimeter of water not one had survived for the period of five days.

Q. How much of the water contained in the sac did you analyze on the 5th day, of table No. 1?

A. The table shows that 3 separate cubic centimeters were examined. These 3 cubic centimeters, together contained initially 36000 typhoid bacilli. Not a single typhoid bacillus was found in this quantity of water at the end of five days, and the conclusion is irresistible that these 36000 had perished.

Your question seems to me to ask for an explanation
10262 as to the significance of the examination of small quantities of water. Assuming that typhoid bacilli were originally uniformly distributed throughout the contents of the sac, each cubic centimeter theoretically contained 12000 bacilli. If these typhoid bacilli are found to have vanished completely from 1 or from 3 cc. of the water after 5 days the inference is plain and unescapable therefore that no typhoid bacilli remain alive in the other 600 or 700 cc. in the sac. It is not the absolute disappearance of each individual that is shown in each of these experiments but the relative and absolute death rate.

Q. Professor, what per cent. of the original 12000 would have given the rigid reaction of typhoid in the event they had been plated immediately after being deposited into the parchment sacs?

A. I believe that all of them would have given the typical reaction if they could have been recovered immediately from the sac.

Q. Did you make an effort at such determination?

A. In one case, table 6, a sample was taken from the sac 10 minutes after infection of the sac, and 1-10000 of the mixture plated in Drigalski medium. Out of 14 colonies taken from this plate 13 proved to be typhoid, indicating a typhoid content of this water of at least 130000.

It should be said, however, that in this case not all of the typhoid like colonies on the plate were picked off.

10263 Q. Is it not a fact, Professor, that in all laboratory experiments, there is a certain percentage of shrinkage from the original number of typhoid bacilli placed in the mixture examined?

A. I think that is so. Some of the bacilli die immediately or very shortly after their introduction.

Q. Is it not a fact that because of the delicacy of the determination that a certain percentage of them are not recovered?

A. Assuming that by delicacy of determination is meant the difficulty of procuring the isolation and correct identification of the typhoid bacillus, I would say that by the use of ordinary media that is undoubtedly true. With the use of these special media, however, that we have employed in this experiment, I think the shrinkage from this source is exceedingly slight. The media used gave results that were to me quite surprising in the accuracy with which typhoid colonies could be differentiated and correctly identified in the presence of other forms.

In this particular case, on table 6, where 1-10000 of a cubic centimeter of water was examined 10 minutes after infection and 13 typhoid colonies were found on this plate, not all of the colonies that might have been typhoid were taken from this plate and it seems to me probable that had all the colonies been taken substantially the same number of typhoid 10264 bacilli would have been found as was originally introduced.

Adjourned until 1:30 p. m., February 13, 1904.

10265 1:30 p. m., Saturday, February 13, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. EDWIN O. JORDAN,

resumed the stand for further cross-examination by Mr. Jeffries, and testified as follows:

Q. State whether or not it was impossible according to the plan used by you in making these special determinations for any of the typhoid bacilli to have been suppressed or withheld from development on the plates?

A. I think it is possible that some slight retardation of development may have occurred in the case of Drigalski and Horrock's media, but there was absolutely no suppression, so far as I could determine, on Hiss's medium.

Q. You did not use Hiss's media on tables 1, 2 and 3, did you?

A. No, sir; these were the earliest experiments and we did not find until the experiment had proceeded for a few days that Hiss's medium was especially favorable. It is my opinion, moreover, that such suppression as occurred was due to a weakening or attenuation of typhoid bacilli which was premonitory to death.

Q. All of the colonies which appeared upon the plates were not fished off of the plates and examined afterwards, were they?

A. No, sir; we very soon learned in the progress of the experiments to distinguish sharply between typhoid-like 10266 colonies and those that were not typhoidal. For example on the Drigalski media the colon colonies were red and could not have been mistaken for typhoid colonies by the most superficial observer.

Q. Were all of the blue colonies fished off?

A. On many occasions, yes, sir.

For example, table 14, after 2 days on MacConkey's medium all of the typhoid-like colonies on the plate were fished and this was usually done, especially after the first 24 hours. This was not true as regards colonies taken from the plates through the first day, since the number of typhoid like colonies was so great that the labor of picking off and examining all of them was so great and obviously unnecessary that it was not undertaken. As soon as the number of typhoid germs seemed to be diminishing, all the typhoid-like colonies were taken off. In the later days of these experiments, that is to say especially after four or five days, it was very difficult to find any typhoid-like colonies on the plates at all and only those colonies could be taken that seemed to bear some semblance, however remote, to the typhoid colonies.

Q. Is it not likely that the colonies which were fished off the plates were merely surface colonies and that there were others which were submerged on the plates?

A. The plates were allowed to develop until the colonies that were at first submerged came to the surface. The submerged colonies in these media in many cases presented
10267 typhoid-like appearances, so that it was not necessary for them to make their way to the surface in order to cause suspicion as to their character.

Q. Was it not necessary in order to obtain or determine the presence of typhoid bacilli in these experiments to have plated at least 10 plates in each instance in order to guarantee accuracy?

A. In this case what was aimed at, as I have stated several times, was the proportionate mortality rather than the absolute presence of a lingering typhoid bacillus in a given quantity of the sewage. If the results showed, when 360,000 per cc. were introduced into the contents of a sac originally, that after three days searching, examination of 1 cc. showed no typhoid bacilli the significance of the experiment is apparent. If such a death rate was maintained during the first three days as to cause the disappearance of 360,000 bacilli from 1 cc. of the water it seems fair to assume that substantially the same mortality had prevailed in the other cc. of the sac. And although it is undoubtedly possible that a few straggling bacilli might have remained alive, even these specially resistant forms would, in my opinion, perish speedily since the mortality rate among the typhoid bacilli generally had proved so very great.

Q. Is it not a fact that the tables of these special observations which you have introduced show that you did not make a searching examination of which you speak in your last
10268 answer, by reason of the fact that in certain instances your examinations ranged from 1-10000 to 1-10 part of a cc.?

A. In reply to this question I would call special attention to the fact that these examinations of relatively small quantities of water to which you refer were in the early days of each experiment, and that on the later days it is true in substantially every case that 1 cc. of the water was plated and examined. The numbers of typhoid bacilli introduced in several of these experiments was so enormous that it would have been absurd to examine larger quantities of the water since the typhoid bacilli were readily found in much smaller quantities.

In table 15, for example, after 5 days, 3 examinations were made, one of 1-10 cc. and two each of 1 cc., and although 857,000 bacilli per cubic centimeter were introduced into the contents of this sac on the day of infection none were found after 5 days in a searching examination made of 1 cc.

Q. Professor, even in the examinations where it shows that you discovered the typhoid bacilli by an examination of a small quantity or a small part of a cc., your tables also show that you failed to find it when at the same time you examined a larger quantity of water. Will you explain why such results pertain?

A. On reference to the tables I fail to find any such constant relation as that stated in your question.

10269 Thus in table 13, after 1 hour 1-1000 of a cc. was plated in Hiss's media, and out of 25 colonies fished 20 proved to be typhoid.

From 1-1000 of a cc. plated in Drigalski, out of 6 fished 4 proved to be typhoid.

From 1-10000 of a cc., also plated in Drigalski, out of 3 colonies fished 2 proved to be typhoid.

From 1-100 of a cc. in MacConkey's out of 15 fished 15 proved to be typhoid.

After 20 hours 3 samples of 1-1000 of a cc. were plated and the typhoid bacillus found in all of them. One sample at this same time was plated in 1-100 cc. and typhoid bacilli were found. The same is true after 28 hours. I am unable to discover in the records of the experiment anything suggesting the condition to which you refer.

On table 14, after 20 hours 3 plates were made from 1-1000 of a cc. and the typhoid bacilli were found in one of these plates; 2 were made from ten times this amount of water and the typhoid bacillus was found on both plates.

After 2 days in this same experiment 2 plates were made of 1-100 of a cc. of water and 2 of 1-10. In both 1-100 cc. samples typhoid were found and in one of those of 1-10.

Such a relation as that indicated in your question does not
obtain, as a general rule, although .certain instances
10270 can be selected from the tables in which the typhoid
bacillus was found among colonies selected with plates
made with a smaller quantity of water while none were found among colonies selected from plates made with a larger quantity of water. This may have been because a larger number of colonies were examined in one case than in the other or because they were not there in the larger quantities of water, although by chance a straggling individual might occasionally be encountered in a small quantity of water.

The same occasional variation is noticed sometimes in examinations for the presence of the colon bacillus, as every bacteriologist has had occasion to determine.

Q. How do you explain a discrepancy of this character as shown from the tables that where 1-10 part of a cc. of water was examined and 1 cc. of the same water was examined at the same time, as, for instance, on the second day of table number 10, shows a larger number of colonies fished out as having the appearance of typhoid bacillus or typhoid colonies in the smaller quantities examined than in the larger quantities of water examined?

A. In referring to the table mentioned, I find there is no statement on this table to the effect that only the typhoid-like colonies were fished from these plates, and as the record stands
in the table no such condition is implied as that indicated
10271 in your quesion. I may say that it happened very fre-
quently in the conduct of these experiments that there
was a very small number of typhoid-like colonies on the plate, and in such cases other colonies were taken in order to extend the number of examinations made. This is the condition to which you refer in table 10, and the same thing obtains in many of the other tables. Especially in the later days of these experiments, it was often very difficult to find any typhoid-like colonies at all. Sometimes colonies had to be taken from plates for examination when their resemblance to genuine typhoid colonies was exceedingly remote and problematical.

Q. Were there not more colonies developed upon the plate when a large quantity was used in the observations than when a small quantity was used?

A. More colonies of all kinds, certainly.

Q. And in such cases was it not more difficult to distinguish true typhoid upon the plates developing the larger quantity of water?

A. Not when the plates were made with the proper quantities of water. The dilutions of the water varying by 1-10 presented no material difficulty.

Q. Then why was it necessary to fish off more colonies in one instance than the other?

A. It was not necessary. It was simply a matter of chance that on some plates more colonies were taken than on
10272 another, except in those instances to which I have already referred, when all the typhoid colonies were taken off a plate as happened in the early days of this experiment.

Q. Professor, on table XIII A, the analysis of the water on the 10th day, where you found the 3 typhoid colonies, I will ask you if those three colonies could not be more readily found in that particular observation than if contained in the one preceding it on the same day, with a smaller quantity of water, but wherein there were a large number of colonies found upon the plate?

A. No, sir, quite the reverse is true. The Hiss medium on the whole, as I have stated several times, differentiated more sharply than the MacConkey medium.

Q. Would they not be more liable to be submerged in the one instance than in the other and disappear on the surface of the plate?

A. If these typhoid colonies had developed on the Hiss plate instead of on the MacConkey they would, in my opinion, have been quite as likely to have been detected as on the MacConkey. The differentiation on the Hiss medium is very sharp.

Q. Professor, were there any analyses made of the water contained in the parchment sac, under table XIII A, on the tenth day, than the two samples shown upon the table?

A. There were not.

10273 Q. After having discovered the three typhoid colonies did you subsequently examine the contents of that sac?

A. As will be noticed by reference to the table, this sac, the record of which is tabulated in table XIII A, was a companion to the one tabulated in table XIII. No typhoid colonies had been found in either of these after the second day, and from the way in which the preceding experiments had resulted, it was supposed a continuous negative result would be maintained so that on the day this sample was taken, the sac was removed from the water. It was not known until some weeks later that the colonies taken at this time were genuine typhoid bacilli.

Q. Were any other efforts made thereafter to examine the water contained in these parchment sacs as long as 10 days whereby various quantities of water were examined by plating out 10 or more plates in each instance for the purpose of making a more correct and accurate determination as to the existence or non-existence of the typhoid fever colonies or germs contained in the water up to and longer than the 10th day, or did you rely solely upon what you had previously found, and attribute this finding to the lodgement of some foreign substance to which was attached a typhoid bacillus upon the parchment and above the water line as the only reason why a further and more extended examination along this line should not be made?

10274 A. As the records show the sac referred to was one employed in one of the later experiments of the canal, and soon after the completion of these experiments all the sacs were removed from the water.

I should explain once more the method of procedure adopted in isolating and identifying the typhoid organisms. The plates were made as soon as the samples were brought to the laboratory and incubated for 48 hours. The colonies developing on these plates were then examined by a long and laborious test taking for its completion several weeks. It was not until long after all the sacs had been removed from the water and the series of experiments brought to a termination, that final identification was arrived at in the case of the most of the typhoid colonies. The results were not known until the whole series was finished and tabulated.

As regards the sudden appearance of these three colonies on a single plate late in one of the experiments I can only say that the most plausible explanation for their appearance in this way is, in my opinion, the one that I have given. According to the doctrine of probability if typhoid bacilli were alive in the water in these sacs between the second and the tenth day they should have been found and their presence noted in some of the many hundreds of examinations made. The fact that 10275 they were not so found indicates, in my opinion that they were not present in the water, but found their way into the sac by some such accident as that I have mentioned.

Q. How many observations were made of the water contained in the sac as shown by plate XIII A?

A. Examinations were made on eight different days, and of 207 different colonies. In several instances, as indicated in the notes at the foot of this table, all of the typhoid-like colonies appearing on the plate were fished and examined. That was the case when 1-10 of a cc. of water was examined on the third day of the experiment. All of the typhoid like colonies appearing on the Drigalski medium and all of those appearing on the MacConkey medium on that day were fished and examined, no typhoid colonies appearing among them. If these three typhoid germs whose presence in one plate was manifested on the 10th day, had been alive in the water throughout this period, it would be reasonable to expect that other straggling individuals would have been found in the interval between the third day and the tenth, especially since quantities as large as 1 cc. of the water were examined several times, beginning as early as the fourth day of the experiment, when on this same medium all the typhoid like colonies were fished and examined.

Q. Is it not a fact, Professor, that as shown by table XIII A the initial colony count of sewage bacteria contained 10276 240,000 bacteria per cc. and colon bacilli at the rate of 1000 bacteria per cc. and typhoid bacilli at the rate of 285,000.00 per cc.; that the sac from which the observations were made contained about 700 cc., and that the 207 colonies fished represented the number of colonies examined for typhoid fever bacilli out of the entire initial number of bacteria contained in the parchment sac on the day of its introduction into the water, the examination of the 207 various colonies taking place from day to day for eight days, beginning three days after the introduction of the parchment sac into the drainage canal at Robey street and continuing for eight days or until the 10th day after the submergence as aforesaid?

A. The question seems to me to involve an entire misconception of the conditions under which these experiments were conducted. I should like to point out that on the 7th day the plate made in nutrient agar, developed with 1-10 of a cc. of water contained only 670 colonies per cc. There is, in other words, an enormous decline from the initial content of the water. To the 240,000 sewage bacteria were added, in this experiment, 285,000 typhoid bacilli, making a total of 525,000 of all kinds, per cc. In 7 days only 6700 bacilli of all kinds were present per cc. in the water of the sac, a reduction in other words of from over 500,000 bacteria per cc. to 6700 bacteria of all kinds.

Instead of the initial number of bacteria in the sac being present, therefore, throughout the conduct of the experiment, the number is very much smaller than was originally 10277 the case, and it seems to me only reasonable to suppose that of this 6700 bacteria present in a cc. of the water on the seventh day the larger number belonged to the more hardy sewage bacteria, while the more delicate typhoid bacillus had perished in even greater numbers than shown by the enormous mortality that prevailed among the sewage bacteria themselves.

It is not proper, therefore, to make comparison between the number of colonies examined in the earlier days of the experiment when the number of bacilli in the sac was large, with the number of colonies examined in the later days of the experiment, when the total number of bacilli in the water had shrunk to such relatively insignificant proportions.

Q. I will ask you, Professor, in view of your last answer, how it is that in a case of the neutral agar, as on the seventh day of table XIII as referred to by you in your answer, developed only 670 colonies while on the ninth day, with the same quantity of water observed, the same plate or character of plate developed 1460 colonies, and I will also ask you if in your answer to the last question you have taken into consideration the number of bacteria that are retarded or suppressed by reason of the earlier character of plates used by you and about which you have testified heretofore?

A. Taking the last part of your question first, I would say that I purposely selected for comparison of colony counts

10278 the ordinary neutral agar plate in which no suppression occurs.

I may add that this was the kind of plate used in determining the initial number of sewage bacteria and so is directly comparable with it.

As regards the appearance of a different number of colonies on the agar plate on the seventh day and on the ninth day, I would say that the difference is so small as not to create special interest or concern in the mind of any bacteriologist who has had experience in plating samples of water. It is possible that the sample taken on the ninth day may have been slightly longer in transit, but even supposing that no such difference in time of plating occurred, such differences in number as that shown between 670 and 1460 are sometimes found in duplicate samples of water plated from the same bottle by the same observer at the same time and in the same medium.

Q. Then from your last answer I assume it to be a fact, generally recognized by bacteriologists, that it is not a safe proposition in making these determinations or in making determinations of this character to use in your investigations less than ten plates at one time in order that the bacterial contents of the water may be properly observed?

A. I do not see how such an inference can be properly drawn from the answer that I have given.

Q. As to the agar plate used by you in your determina-
10279 tions that degree of suppression or retardation of ordinary water or sewage bacteria did not take place as was stated by you in your direct examination in reference to these tables and these experiments to be one of the objects of this particular character of work?

A. I made the statement that the Drigalski and MacConkey media, as used by me, suppressed a large number of the ordinary sewage bacteria. I did not intend to make nor do I believe that I made the statement that neutral agar was used for the purpose of suppressing such forms.

I may add that the neutral agar plates that appear in some of the tables were made primarily with a view to determining the correct colony count for exact comparison with the initial number of bacteria, since the initial number of bacteria as given under the head of each table was ascertained by the use of this neutral agar media.

Q. But is it not a fact, Professor, that the 207 colonies fished from the plates as shown by table XIII A are the only colonies developed from the contents of the parchment sac at that place which were specifically examined for typhoid determinations?

A. That is correct. These were the only suspicious typhoid-like colonies that were examined. I would point out, however, that 170 of these were examined before the 10th day, not a single typhoid colony being found among them.

10280 On the 10th day out of 13 colonies taken from one plate 3 proved to be typhoid.

Q. Is it not also a fact that during the 8 days only 7.02 cc. of the 700 cc. contained in the parchment sac were developed, on Table XIII A?

A. I have already pointed out the fallacy of interpretation involved in such a question and any direct answer that could be given to it. The rate and extent of mortality among the typhoid bacilli is the significant thing in these tables rather than the quantity of water examined.

I should, however, like to point out that even viewed in the narrow sense in which your question is asked that this quantity of water, namely, 7.02 cc. contained originally about 20,000,000 typhoid bacilli and that in the course of 8 days examination only 3 typhoid bacilli were found.

Even when looked at in this way which seems to me open to misconstruction it is certainly a highly remarkable and significant fact that out of 20,000,000 bacilli only 3 should be found even assuming what in my opinion is not correct, namely, that these 3 typhoid bacilli had remained alive in the waters of the sac during this long period of investigation.

Q. On the 10th day, Professor, as shown by table XIII A, only the surface colonies were fished, were they not?

A. Yes, sir, according to the statement made in the note.

10281 Q. These sacs, as they were suspended in the water, were well shaken each day, were they not?

A. Yes, sir, Mr. Irons, who had charge of collecting the samples was under specific instructions from me to mix thoroughly the contents of each sac before taking samples, and I have every reason to believe that he followed out these directions.

Q. Did the water in these sacs extend to the glass tube, the upper end?

A. I think in some cases it did. I am not sure about all the sacs.

Q. Could this deposit containing the 3 bacilli of typhoid as shown on table 13, on the 10th day, have remained there any length of time without having been disturbed, as explained by you in your direct examination?

A. I see nothing improbable in that assumption. A particle of organic matter in the sewage with typhoid bacilli adhering to it and lying underneath it, might adhere to the glass and remain there for several days finally to be dislodged by some special accidental occurrence.

Q. Knowing that those conditions would likely pertain should not a more extensive or extended analysis of the water be made than was made, in order to determine its bacterial condition?

A. In reply, I would say that if I understand the question correctly it implies that this source of error might have been foreseen. As a matter of fact it was not foreseen by me
10282 and the possibility of an accident of this character did not occur to me until after the experiments had been closed.

I do not regard, however, the general outcome of these experiments or the deductions to be drawn from them as affected by this accidental occurrence.

Q. Professor, in your direct examination you spoke of the great care urged upon Mr. Irons in shaking each time the contents of the sac and running the water up into the glass tube, so that the water could be drawn with a pipette. In this case would not the sides of the tube and the parchment sac have to be washed down each day, if your instructions had been carefully obeyed?

A. I have already answered that question. It seems to me that a particle of suspended matter present in the sewage at the time a large number of typhoid bacilli were present might adhere with such tenacity to the glass as not to be washed down during a series of examinations.

I should also like to call attention in this conneciton to the fact that no samples were taken from this particular sack until 3 days after the infection of the tube. The washing up of the sewage from the sack into the tube, due to agitation of winds, etc., might have caused some of these particles to dry with such firmness in the first few days, that subsequent motion over them
in the process of agitating the contents of the sac did not
10283 dislodge these firmly adhering particles. An exceedingly
minute concrete particle in the sewage, no larger than the point of a needle, might have clinging to it many thousands of typhoid bacilli.

Q. Professor, how long after these parchment sacs were suspended in the water before they became coated with this bryozoan?

A. This growth was especially noticed in the sacs set in the canal at Robey Street. The coating appeared, as I recall it, in some 8 or 9 days after the sacs were immersed.

Q. Did you not state, Professor, in your direct examination that it appeared upon the sacs within two or three days?

A. There may be some confusion as to the time of appearance of a slime on the walls of these sacs and the appearance of the bryozoan.

Q. How soon did the slime appear after the sacs were submerged?

A. At Robey Street usually within two or three days.

Q. Were these parchment sacs of sufficient strength to hold the water?

A. They were.

Q. Were they air tight—I mean by that, would they permit the diffusion of air through the walls of the sac? Before the water was put into them?

A. I think not, but I am not sure on this point.

Q. Would they hold the water within the sac while sus-
10284 pended in the air?

A. Yes sir, they were tested on that point. I am speaking now of the sacs that were used in the experiment. Some sacs were found defective, having been injured in the process of making, and these were discarded. The sacs used in the experiment were tested in that direction.

Q. What were the differences between the parchment sacs and the celloidin sacs or receptacles?

A. One difference was that the celloidin sacs were a little more fragile and had to be handled more carefully and kept moist to avoid breaking. Diffusion takes place a little more rapidly in the celloidin sacs when they are made properly, otherwise the conditions are very similar.

Q. Did these slimy substances form on both the celloidin and the parchment sacs?

A. In my experiments I had no celloidin sacs in the water of the drainage canal.

Q. Is it not a fact that the formation of the slime and the bryozoan upon the exterior of the sacs prevented diffusion through the walls of the sacs, rendering the conditions exactly similar to a laboratory experiment?

A. I do not see how this could have been the case. The formation of slime may have retarded diffusion in some slight degree, but I do not see how it could prevent it altogether or even hinder it materially. As evidence of the similarity of conditions prevailing in the slime coated sacs in the drainage
10285 canal and sacs not so coated with slime I may instance the
laboratory experiments that I made, when the sacs did not become coated with slime, but the course of events in these sacs ran a parallel course to that obtaining in the slime coated sacs in the canal showing essential identity of conditions as far as the bacterial life was concerned.

Q. Would not that retardation of the diffusion depend upon the extent of the formation of the brazoa upon the exterior of the sacs?

A. It might to some extent, but the sacs were carefully observed with this very point in mind, and no material difference was found in the behavior of sacs rather heavily coated with slime and those relatively free from it. The changes in the bacterial content of the sacs were very much the same at Robey Street and at Lockport, although on the sacs at Lockport there was relatively very little slime.

Q. How can you tell that there was diffusion in those sacs coated with slime and Bryozoa.

A. I have already stated that the events shown to take place in the slime-coated sacs and in those without such slime coating were substantially the same. I see no grounds for assuming that the coating of slime could materially retard diffusion.

Q. Do you understake to say that there was that same diffusion from within and without the sac as there would be and was during that time in the running water of the canal?

10286 A. I believe the conditions to be essentially the same.

Q. In what way do you use the word essentially?

A. So far as products affecting the life of the bacteria are concerned.

Q. Do you believe that the diffusion through the walls of the sac was sufficient to permit the products and by products of the bacterial contents of the water in the sac to pass through the wall and out of the sac, and also the products and by-products of the bacteria in the water itself to pass from the main body of the water into the sac under the same conditions and to the same extent as it would be diffused, distributed and mixed as though in the running stream?

A. Some of the products and substances would in my opinion not be readily diffusible. Assuming, however, that no diffusion whatever occurred, the changes that take place in the content of the sac would be still of the utmost significance since there would be simply a portion of the water of the canal present under similar conditions of temperature, in each of these sacs and whatever took place in such a body of water might be reasonably assumed to take place also in the waters of the canal.

Q. That answer is based altogether upon the proposition that all parts of the water in the canal are equally charged with polluting material from substances and that the bacterial counts are the same at all times at that particular place in the
10287 canal during the 8 days that the parchment bag was suspended in the water, is it not?

A. That is not quite correct for the reason that reference to the tables of the experiment will show that the water into which the typhoid bacilli were introduced varied considerably in bacterial composition in the different experiments.

Q. Professor, if these sacs became coated with slime which you have referred to in your direct examination, is it not a fact that they thus became impervious to all substances and impervious to dissolved oxygen?

A. I do not know that that is so, but assuming that it were true the fact still remains that the changes in the bacterial content of these sacs are the same whether the sac be coated with slime or not.

So far as dissolved oxygen is concerned, there is probably very little if any of this in the waters of the drainage canal and I may further recall the fact that the tubes were open at the top and freely exposed to oxygen.

Q. It is your opinion then that there is very little dissolved oxygen in the waters of the canal?

A. In a water of the character of that in the drainage canal I do not well see how there could be much dissolved oxygen.

Q. And there would be less in the parchment sac used in these experiments, would there not?

A. I have no means of knowing whether there would or would not.

Q. Professor, you analyzed bacterially the waters of
10288 Lake Michigan during the prevalence of typhoid fever in
Chicago did you not, prior to the opening of the drainage canal?

A. Yes sir, I have made a number of examinations of Lake Michigan water as drawn from the tap in the University laboratory.

Q. State, Professor, whether or not there were more bacteria in the waters of Lake Michigan, as shown by the colony counts upon your examination, than there were in the waters of the Illinois River at any point examined by you during this entire investigation?

A. Yes sir, I have several times found more bacteria in water drawn from the laboratory tap than found at Averyville and at Grafton.

Q. As a general proposition was not the reverse true, in this to-wit: that you found more bacteria as shown by the colony counts in the waters of the Illinois River than in the waters of Lake Michigan?

A. I have not made a sufficiently extended examination of Lake Michigan water for a long period covering different seasons of the year, different wind and temperature conditions, etc, to be able to answer that question.

I may also mention that a decline in the numbers of bacteria usually takes place as a water passes from mains and service pipes so that the conditions in Lake Michigan may not be correctly represented by the colony count obtained upon samples of water drawn from a tap.

10289 Q. Prior to the opening of the drainage canal how far out in Lake Michigan was the water of the lake affected by the sewage of Chicago, if you know?

A. I do not know.

Q. Did you make any examination on that subject?

A. I did not.

Q. Professor, assuming that typhoid fever germs pass to the bottom of a body of water, either a river or a lake, and become deposited in the sediment, I will ask you if it is not more likely that such germs would afterwards be washed out and removed from the sediment, if deposited in the bed of a river than if deposited in the bed of Lake Michigan, opposite the mouth of the Chicago River, taking into consideration the average depth of a river, together with the depth of the water in Lake Michigan at the given point?

A. Assuming what seems to me contrary to the fact, namely, that typhoid bacilli can be deposited in such sediment and maintain their vitality for any considerable period, it would of course follow that where changes in the surroundings and velocity were very pronounced such germs would be more likely to be picked up and carried along than in cases where the bottom ooze was not disturbed.

Q. Assuming, Professor, that typhoid fever germs are 10290 carried out into Lake Michigan and deposited in the sediment of the lake would they be afterwards taken up and be carried into the water supply of the City of Chicago as freely and to the same extent as though they had been deposited in such a running stream?

A. Assuming indefinite continuance of vitality on the part of the bacillus I should say that the answer to that question depended upon the extent to which the sediment in the bed of Lake Michigan was infected and the degree to which such infected sediment was disturbed. I do not know how frequently or how profoundly such sediment is stirred up and becomes mingled with the water. The water as drawn from the tap is certainly very turbid at certain times.

RE-DIRECT EXAMINATION,
By Mr. Todd.

10291 Q. Professor, will you distinguish between the terms "presence of sewage" and "effect of sewage" as the terms were used by you in answer to a question of Mr. Jeffries?

A. When I stated that the effect of sewage was present in the waters of the Illinois River at Averyville or Grafton, I referred of course to the fact that the chlorine present in such large quantities in Chicago sewage was manifest in the water of the Illinois River at this point, and also the fact that the large amount of nitrogenous matter introduced into the Chicago sewage was shown by the amount of nitrates and other nitrogenous compounds present in the water of the Illinois River at Averyville. The effect of the addition of sewage to such a river water as shown in the chlorine and the nitrogenous content might persist for hundreds and thousands of miles
10292 irrespective of any change that might occur in the sewage itself. Thus, the chlorine would not disappear from the water of the river if the river were thousands of miles instead of hundreds of miles long.

I should make this distinction between the effect of sewage and its presence.

Q. On cross-examination you were asked several questions pointing to the possibility of the typhoid bacillus being able to swim away from injurious or toxic substances? Do you know how fast this bacillus can move?

A. Some investigations have lately been published on the speed of a typhoid bacillus in the Archiv fur. Hygiene, 1903, 46, page 311, by Lehmann and Fried. These show the results of careful measurements made of the speed of the typhoid bacillus and other bacteria. The mean of the highest and the mean of the lowest observations are given in this paper. Moving at its highest speed a typhoid bacillus was found to move at the rate of four and one-half (4 1-2) inches in an hour, the minimum rate being about one-fifth of this. From one to five inches per hour, therefore, would represent the speed with which a typhoid bacillus could move.

10293 In a river flowing at the rate of half a mile an hour the velocity of the current then would be about 5,000 times as great as that of the typhoid bacillus, so that this organism would be helplessly borne along and brought into contact with various toxic substances without being able to remove itself from their neighborhood.

RE-CROSS EXAMINATION

By Mr. Jeffries.

Q. Do you know of any means of determining accurately and definitely the velocity which may be obtained by the typhoid fever germ in water?

A. These data that I have referred to afford the most recent information that I know of bearing on this subject. The measurements were carefully made with the microscope. It does not seem likely that under natural conditions the velocity would vary more than shown by the figures obtained by these investigators.

Q. There is nothing in those experiments that show that any artificial means was used for the purpose of producing the most rapid probable velocity of these particular germs?

A. The observations on other species of bacteria made
10294 at the same time with those upon the typhoid bacillus
show that even those species of bacteria known to be most highly motile do not vary in their speed very much from the figures thus quoted. The typhoid bacillus itself is a very actively motile organism and a rate of 10 to 12 inches an hour would be an enormous speed for any microbe under any conditions.

Q. Do you know the volume of the particular particles of toxic products that are generally found in polluted waters?

A. In regard to the nature of these so called toxic products in water very little is known, as I have already stated in my testimony. They are, however, doubtless in solution and not in the form of concrete solid particles.

Q. A very short space of removal may only be necessary, to bring the particular bacilli away from the disturbing toxic products into more formidable surroundings, may it not, taking into consideration the size of the particular bacilli?

A. I should think that would not be the case for the reason that the diffusion of dissolved substances through water takes place at a very rapid rate and it seems unlikely that there should be a much greater concentration of these toxic bodies at one point in a mass of water than at another. The diffusion through the water and the mixing caused by the moving
10295 would tend to bring about a very uniform condition of the water within a space of several feet.

Q. Then by the addition of water the diffusion becomes more scattered and less concrete and effective, so far as its deleterious effect upon the bacilli is concerned?

A. I have already stated that that is in my opinion the most plausible explanation for the more rapid disappearance of typhoid bacilli in highly polluted waters as compared with pure waters, namely the greater concentration of the toxins in the sewage polluted waters.

Q. Professor, from your answer to the first question put to you by Mr. Todd, in re-direct examination, in which you described the difference between presence of sewage and effect of sewage chemically speaking, in water, do I understand you to say from that that none of the bacterial counts which may be found in the Illinois River at Averyville come from Chicago, and that all bacteria originating at the city of Chicago have disappeared before Averyville is reached? I mean by that, all bacteria of every kind and character that may be deposited or discharged into the Chicago River or the drainage canal at Chicago?

10296 A. Taking into consideration the enormous number of bacteria and the large number of species discharged into the drainage canal at Chicago and the relatively small number of bacteria found in the water of the Illinois River at Averyville, and taking into consideration also the continuous discharge of bacteria into the Desplaines and Illinois Rivers between Lockport and Averyville, from the sewers of Joliet, La Salle and from the drains of many smaller streams or places, it seems evident that by far the larger number of germs introduced by the Chicago sewage must have perished long before Averyville is reached. Whether every individual bacterial cell entering the drainage canal perishes before reaching Averyville is a matter difficult to determine. There is this indirect evidence, however, gathered from the composition of the various streams tributary to the Illinois. These streams, such for example as the Fox, the Sangamon and others, have not received the drainage from Chicago and yet their bacterial content, so far as numbers is concerned, is almost identical with that of the Illinois River at Averyville.

From my study of species of bacteria isolated from the Illinois River at Averyville as compared with the species
10297 present in the Chicago drainage canal it seems to me
unlikely that any significant numbers of bacteria find their way from the canal to Averyville.

It is impossible to state, however, that some bacteria belonging to saprophytic species adapted to an aquatic life may not survive long enough to pass from the drainage canal to Averyville.

Q. It is your opinion, then, is it Professor that no sewage bacteria or pathogenic bacteria of any kind or character, originating in the sanitary district of Chicago and discharged into the Chicago River or drainage canal pass down the Illinois River as far as Averyville under all conditions that have existed or may exist in the future?

A. I certainly should not be willing to express an opinion as to what might obtain under future conditions.

Using the term pathogenic bacteria in the way which I assume that it is meant, I would say that it is my opinion that few if any pathogenic bacteria pass down the Illinois River under existing conditions as far as Averyville.

10298 Q. But you will not say that they do not pass down as far as Averyville?

A. It is impossible to say that a few straggling individuals may not pass so far, just as it is impossible to affirm that they do pass as far as Averyville.

Q. Now, Professor, in what way do you assume that the term pathogenic bacteria is used in the question and as expressed in your answer?

A. I understood you to mean the pathogenic bacteria ordinarily regarded as pathogenic for man.

EDWIN O. JORDAN.

ADJOURNED UNTIL 10:00 A. M., MONDAY, FEBRUARY 15, 1904.

10299 10 A. M., Monday, February 15th, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

N. MAC L. HARRIS,

a witness called in behalf of the defendants, having first been duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION BY Mr. Todd.

Q. State your name?

A. Norman Mac Leod Harris.

Q. What is your business?

A. I am employed as an assistant in the Chicago University, Associate in Bacteriology.

Q. Under whom do your duties fall?

A. Under Professor Jordan.

Q. How long have you been connected with the University of Chicago?

A. Since June 15th.

Q. What business were you connected with, prior to that time?

A. I was associate in Bacteriology at Johns Hopkins University.

10300 Q. For how long?

A. From October, 1897, to May, 1903.

Q. Under whom did your duties fall, in the Johns Hopkins University?

A. Under Prof. Wm. H. Welch.

Q. From what institution did you graduate?

A. From the University of Toronto.

Q. Did you take a Post-Graduate degree anywhere else?

A. Yes sir, in London, England, I obtained the diploma of the Royal College of Surgeons, and Licentiate to the Royal College of Physicians, London.

Q. Did you do any work under the direction of supervision of Prof. Jordan, for the Sanitary District of Chicago, in connection with an experiment made in the Drainage Canal?

A. I did.

Q. What part of that work did you perform?

A. The preparation of certain media used for the concentration of the organisms.

Q. Were the preparations of these media done by you according to the directions and under the supervision of Prof. Jordan?

A. By myself, upon consultation with him, upon certain points.

Q. After the media were prepared, what did you do in connection with the experiments?

10301 A. My duties were the identification of the organisms, isolated by Miss Lincoln, who was an assistant.

Q. And were you and Miss Lincoln in the laboratory together?

A. Not in the same room, we were working apart. Occasionally I would go in and see her work.

Q. Miss Lincoln is the lady that Prof. Jordan referred to as being his assistant in his laboratory there?

A. Yes sir.

Q. After the identification of the bacteria was made—this identification was made under the direction and supervision of Prof. Jordan?

A. It was.

Q. After that was made, what else did you do?

A. I simply kept a record of my daily work.

Q. And were these records submitted to Prof. Jordan?

A. They were.

Q. As the work progressed?

A. Yes sir.

Q. And everything you did in connection with the experiment, was done under the direction and supervision of Prof. Jordan?

A. Yes sir.

Q. After you obtained the instruction he gave, in regard to the method to be pursued?

A. I did.

10302 No Cross Examination.

Signature Waived. F. S. B., Com'r.

ERNST E. IRONS,

a witness called in behalf of the defendants, having first been duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION BY
Mr. Todd.

Q. What is your name?

A. Ernst E. Irons.

Q. What is your business?

A. I am assistant in the University of Chicago, in Bacteriology.

Q. Are you employed there now?

A. Not during the present quarter, no.

Q. But do you still retain your connection with the university?

A. I do, at present.

Q. What are you doing now?

A. I am in the Presbyterian Hospital as interne.

Q. When did you graduate?

A. In the University of Chicago, in 1900.

Q. After your graduation, what did you do?

A. I was associated with Prof. Jordan, in bacteriology.

Q. How long were you connected with the university under Prof. Jordan in bacteriology?

A. From January, 1897.

10303 Q. Did you do any work in connection with streams examination, under the direction of Prof. Jordan, in the year 1899 and 1900?

A. I did.

Q. At what place did you do the work?

A. At the University of Chicago.

Q. This work was done in connection with the examination of what rivers?

A. The Illinois river, and the Mississippi and the Missouri.

Q. The results of that examination has been published in what is known as Streams Examination by the Sanitary District?

A. It has.

Q. As well as in the tables introduced in evidence by Prof. Jordan?

A. Yes, sir.

Q. What part of that work, in a general way, did you do?

A. I made the bacteriological examinations.

Q. Did you receive the samples as they came into the laboratory from the water takers?

A. I received part of them in association with Mr. Stevens.

Q. And after the samples were received by you, what was done with them?

A. They were properly labeled, identified and examined.

Q. The examination that you pursued in this matter
10304 was the examination under the direction of Prof. Jordan?

A. Yes, sir.

Q. For that period?

A. Yes, sir.

Q. And all the reports you made were given directly to him?

A. Yes, sir.

Q. This laboratory is his working laboratory that you worked in?

A. It was.

Q. And under the immediate supervision of Prof. Jordan?

A. Yes, sir.

Q. And the results of those examinations that you have heretofore indicated, are the tables that are published and which have been testified to be Prof. Jordan's tables?

A. Yes, sir.

Q. All the work you did in connection with these examinations, was done under the supervision and under the direction of Prof. Jordan?

A. Yes, sir.

Q. Mr. Irons, did you do any work under Prof. Jordan, in connection with the colony count, and the coli determinations, for the period of 1901?

A. I did.

Q. What work did you do?

A. I established laboratories at Peoria, Grafton, and
10305 St. Louis. My chief work was at St. Louis, but from
time to time I was at Peoria and Grafton for a day at a time.

Q. In establishing these laboratories, under whose directions were you acting?

A. Under Prof. Jordan's.

Q. Do you know whether the City of St. Louis had laboratories established at these three points at the time the laboratories were established by you?

A. They did.

Q. Do you know whether water was taken from the same points in the river, that water was taken for the laboratories you have just testified as having been established at these three points?

A. So far as I know, the samples were taken at Peoria, from the same points. At Pekin, I do not know, I am not sure about that. At St. Louis and Grafton, I believe the samples were taken at the same points, so far as I know.

Q. What laboratory did you have charge of?

A. The St. Louis Laboratory.

Q. Who else was there in connection with you?

A. Mr. Sackett.

Q. That is the gentleman that has already testified in this case?

A. I think he has.

10306 Q. At what points was the water taken that was analyzed in the St. Louis Laboratory?

A. From the Mississippi river, Chain of Rocks, four samples, and from the Missouri river, at Bellefontaine.

Q. What determinations were made from the water thus secured from these places?

A. Determinations of the colony count and colon determinations.

Q. How long after the water was taken, was it before they were plated?

A. In the case of the samples at the Chain of Rocks, the samples were examined on the spot in a temporary laboratory fitted out at the Chain of Rocks, that was done by Mr. Sackett. The samples from Bellefontaine, Missouri river, were brought to the laboratory, arriving in about two hours after collection.

Q. All these determinations made by you and Sackett were tabulated?

A. They were.

Q. And the results reported to Prof. Jordan?

A. They were.

Q. Were these examinations made in pursuance to directions given you by Prof. Jordan?

A. They were.

10307 Q. Were these examinations made in pursuance to directions given you by Prof. Jordan?

A. They were.

Q. And under his directions and supervision?

A. They were.

Q. After you had completed the work at St. Louis, what was done with the results of that work?

A. Prof. Jordan had charge of all the results.

Q. They were sent to him?

A. They were.

Q. Those are the results of that laboratory that has been offered in evidence here by Prof. Jordan, and you are the assistant that did the work under his direction, that he has testified to?

A. I am.

Q. Did you do anything under the direction of Prof. Jordan in connection with an experiment made in the drainage canal, for the Sanitary District of Chicago?

A. I did.

Q. State what you did?

A. I had certain boxes constructed and placed in them
10308 parchment sacs containing various cultures, and samples of water.

Q. From whom did you get the parchment sacs?

A. The parchment tubes were bought from a chemical company in the city, and were made into sacs by me.

Q. How did you make the sacs, just describe the process?

A. I cut off sufficient sizes, or pieces of tubing from the roll, and fitted in the upper end a glass tube, about ¾ of an inch in diameter, and rolled up the lower end in such a way as to seal it. The joints at the upper end and the lower end were then saturated in a solution of rosin and tallow, and bound around with twine. After construction, the sacks were tested in the laboratory to see that there were no breaks in them.

Q. Did the sacks come as tubing?

A. They did.

Q. What test did you employ to ascertain the integrity of the sacs?

A. The sacs were moistened, filled with water, suspended, and then observed to see if any minute points of fracture appeared in the outside, which would indicate perforation.

Q. After you had prepared the sacs in the manner that you have indicated, did you use any sacs that gave
10309 evidence of perforation?
No, sir.

Q. After the sacs were prepared as you have indicated, what was then done by you?

A. The sacs were taken out to the drainage canal and filled with the water in the canal. After they were filled they were again suspended and observed to see whether there were any perforations. In case there was a perforation, the sack was thrown out.

Q. Then what was done?

A. The sacs were suspended in the wire cage. Some of them were inoculated with typhoid cultures which had been previously obtained, and some of them were allowed to remain without any inoculation.

Q. What were those sacs called that were not inoculated?

A. They were called control sacs.

Q. The sacs that were inoculated, what were they inoculated with?

A. They were inoculated with suspensions of typhoid bacilli.

Q. What do you mean by suspensions of typhoid bacilli?

A. A colony of typhoid was grown in the incubator for 24 hours in bouillon, then a portion of this culture was
10310 placed in sterile normal salt solution in a flask.

Q. Who prepared these cultures of the typhoid bacilli?

A. Do you mean originally?

Q. Yes, sir?

A. There were three cultures employed, obtained from the bodies of typhoid patients by Dr. Rosenow, at the county hospital.

Q. Did you secure these cultures from Dr. Rosenow?

A. Directly, yes, sir.

Q. After you secured them from him, what did you do with them?

A. I handed them to Prof. Jordan.

Q. And then, when did you get hold of them again?

A. I received them at the laboratory from Dr. Harris, who had examined them in the mean time.

Q. In what form did you receive them from the media?

A. In agar streak cultures.

Q. Then what did you do with them?

A. I made a bouillon culture for each of them as required and inoculated them after 24 hours into a normal salt solution.

Q. How were these typhoid strains designated?

A. As typhoid X, Y and Z.

10311 Q. Now, after you prepared the culture in suspension, as you have described it, what was done with it?

A. A certain amount of the suspensions was placed in certain of the sacs, which had been placed in the wire cage in the canal.

Q. Now, how were the sacs numbered?

A. The sacs were numbered A. B. C, and so on, down the alphabet, the letter designating a certain series, and then a number of similar sacs of the series was made. These were designated A 1, B 1, etc., and A2 B2, and so on.

Q. And after the box was prepared, and the sacs inoculated, and placed in the water, was this in accordance with the instructions given you by Prof. Jordan?

A. That was all under his instructions.

Q. Then what did you do?

A. After inoculating the sacs, and agitating them, samples were removed from the sacs for immediate examination.

Q. Will you describe what you mean by agitating the sacs? 10312

A. Attached to the lower end of each sac was a cord, which is brought up and tied to the rack holding the neck of the sac. The bottom of the sac was alternately brought to the surface and lowered, this was done repeatedly for ten or fifteen times.

Q. Then after you had agitated the sac, what did you do?

A. Samples were taken from the sac.

Q. What means were employed for taking samples?

A. I used sterile 10 c. c. pipettes with a rubber bulb attached to the upper end. The sample of the water was drawn up in these pipettes and placed in sterile 50 c. c. bottles.

Q. After it was placed in the sterile bottles, then what was done?

A. The bottles were sealed and taken to the laboratory at the University.

Q. And after they were taken to the laboratory at the University, what was done with them?

A. They were examined by Miss Lincoln.

Q. And then what was done?

A. That was where my work ended.

Q. Did you keep a record of what you did?

A. I did.

10313 Q. Did you keep a record of the time at which the samples were taken?

A. I kept a record of the time they were inoculated, and the time they were removed, and the time they were delivered at the laboratory, and the condition of the cage, and sacs, at each visit.

Q. What was done with the record that you kept?

A. It was handed to Prof. Jordan.

Q. When you put these sacs in the water, did anything form on them?

A. There was a growth of water organisms which, on examination, proved to be brazoa.

Q. How soon after these sacs were placed in the water, did these brazoa appear on the outside of the sacs?

A. Little small spots began to appear about the third or fourth day, about the fourth day, and these gradually became larger, so that after a number of days there was a coating over the surface of the sac.

Q. About how many days does it take to make a complete coating over the surface of the sacs?

A. I should say about 14 days.

Q. Did the brazoa appear on the sacs at Robey street and at Lockport?

A. At both places.

Q. At the same time and in the same quantity?

10314 A. No, they appeared somewhat earlier at Robey street, so far as I was able to observe.

Q. Did they appear on all the sacs uniformly?

A. Not entirely uniformly, the position in the box seemed to make some little difference, but I was unable to determine just what the reason was.

Q. All of the work which you did in connection with this experiment as you have detailed it, you reported to Prof. Jordan?

A. I did.

Q. And was done under his direction and supervision?

A. It was.

Q. Did you at any time make any examination of the water of the Mississippi river at Quincy, Illinois, for the purpose of determining the presence of the bacilli coli communis?

A. I did.

Q. When did you make this examination?

A. That was in the fall of 1902, in September and October, and in December, 1902, until February, 1903, and a week in March, 1903.

Q. For whom did you make this determination?

A. This determination was made in connection with some
work that I was doing for the American Steel and Wire
10315 Company, in connection with sulphate of iron for the
purification of water.

Q. Have you prepared a table showing the results of your examination of the water of the Mississippi river at Quincy, for that time?

A. Such a table appears in the report that I made.

Q. Was that table made by you?

A. It was.

Q. Who took the samples of water?

A. I took them, myself.

Q. All this work was done by you personally?

A. Yes, sir.

Q. Was the same method pursued in this examination that was made for the coli determinations in the laboratory at St. Louis?

A. Practically the same, yes, sir.

Q. Will you read the table in evidence that you prepared there of the waters of the Mississippi river at Quincy?

A. It is as follows:

10316 TABLE

Showing the relative frequency of occurrence of B. coli communis in Mississippi river water at Quincy.

Date.	No. of samples.	.001 c. c.			.01 c. c.			.1 c. c.			1. c. c.		
		+	—	?	+	—	?	+	—	?	+	—	?

Q. Did you examine the results of the coli determination at the station of Grafton?

A. I did.

Q. Were you there at that station?

A. From time to time I was. About every two weeks.

Q. How does the presence of coli bacilli in the Mississippi river at Quincy compare with the coli bacillus at Grafton?

A. Judging from the determinations that I made during the course of my work for the Steel Company, the colon bacillus was much more numerous in the Mississippi river at Quincy than it is in the Mississippi river at Grafton, or of

10317 the Illinois at Grafton.

CROSS-EXAMINATION, by Mr. Corum.

Q. Mr. Irons, from what school are you a graduate?

A. University of Chicago, and Rush Medical College.

Q. Where are you employed now?

A. As interne in the Presbyterian Hospital.

Q. When did you graduate?

A. At the University of Chicago, in 1900.

Q. From Chicago, in 1900?

A. Yes, sir.

Q. Did you attend any school since that time?

A. The Rush Medical College.

Q. And you graduated from that school?

A. Yes, sir, in 1903.

Q. What time in 1903?

A. December, 1903.

Q. How old are you?

A. Twenty-six years old.

Q. Now, these experiments that you made, were made under the direction and supervision of Prof. Jordan?

A. They were.

Q. In each instance you did as you were told to do by him?

A. With the exception of this Quincy matter, yes, sir.

10318 Q. You were then working for the American Steel and Wire Company?

A. I was.

Q. Now, you say you placed some laboratories at Grafton?

A. At Grafton, Peoria and St. Louis.

Q. When did you place this laboratory at Grafton?

A. That was about September 28th.

Q. Of what year?

A. 1901.

Q. How long did that remain there?

A. The Grafton laboratory remained in operation until December 15th, I think.

Q. 1901?

A. 1901.

Q. Did you personally superintend it during its existence?

A. Mr. Sayer had charge of the laboratory.

Q. You were not present there at all times?

A. No, I was not.

Q. At what other point did you place a laboratory?

A. At Peoria and St. Louis.

Q. When was the laboratory placed at Peoria?

A. The first week in October, 1901.

Q. How long did that remain?

A. Until about January 10th, if I remember.

10319 Q. Did you personally superintend that one?

A. Mr. Schule had charge of that laboratory.

Q. You were not there present at all times?

A. I was not.

Q. The other laboratory, did you personally superintend that during its existence?

A. I did.

Q. At all times?

A. At all times except when I was called away on other matters.

Q. Now, you stated that you took four samples from the Chain of Rocks in the Mississippi river?

A. Four samples were taken.

Q. Did you take those?

A. We had collectors who took those samples under the direct supervision of Mr. Sackett.

Q. Now, as I understand, you took some sacs out to the canal, yourself?

A. I did.

Q. How many of those?

A. Between 30 and 40, I should judge.

Q. And where did you place those?

A. They were placed in the canal at Robey street and at Lockport.

Q. Near each other, and how close were they together, those at Robey street?

A. The sacs were placed at Robey street in a box 4 feet long and 3 feet wide.

10320 Q. All in that box?

A. All the sacs were not in the box at the same time. because several of the experiments were repeated from time to time.

Q. Now, those at Lockport, did you say?

A. At Lockport.

Q. Now, how were they placed?

A. They were placed similarly.

Q. In a similar kind of a box?

A. In a similar kind of box.

Q. What sort of sacs were they?

A. They were parchment sacs.

Q. Were they such as to admit the diffusion of air?

A. The upper end of the tube was open to the air.

Q. But would the sacs themselves permit the air to be diffused?

A. The sacs themselves were beneath the surface of the water.

Q. What remained above the water, how about the diffusion of air, what remained above the water?

A. That would allow the diffusion of air, the same as most solids will allow the diffusion of a small amount of gas, if long enough time is allowed, but ordinarily speaking, it would not.

10321 Q. What do you mean when you say ordinarily speaking?

A. There were no punctures in them.

Q. They would not permit it, unless they were punctured, is that the idea?

A. Any parchment membrane will allow the diffusion of a small amount of air if long enough time is allowed.

Q. Now, before these sacs were taken out did you test them thoroughly as to whether they would permit the water to soak through?

A. At the time of removing each sac, it was inspected in the same way, it was inspected when placed there.

Q. I mean prior to placing them in the canal, did you give them a thorough inspection to see whether there was any leakage?

A. I did.

Q. Test them thoroughly?

A. Yes, sir.

Q. Then, when you took them out to the canal they were not tested again?

A. They were.

Q. Why, if they had been thoroughly tested before?

A. As a matter of scientific exactness, they were tested again.

Q. And you did not detect any leakage on either test?

A. If there was a leakage, it was reported at the time.

Q. And then what was done with those sacs?

10322 A. They were thrown out.

Destroyed?

A. Yes, sir.

Q. After these sacs were put in the box, they were permitted to remain there, as I understand, for different times?

A. They were.

Q. How long was it until you removed the first sac?

A. Only a matter of three or four days.

Q. Did you remove the first sac?

A. I did.

Q. What did you do when you removed it?

A. I removed the entire contents for a chemical examination.

Q. What did you do with the contents?

A. Took it to the University.

Q. Take it along in the sacs?

A. It was taken in a chemical bottle.

Q. Was the bottle sealed?

A. The bottle never passed from my possession until it was delivered. The bottle was sealed and did not pass from my possession until it was passed to the person who was to examine it.

Q. You made a chemical analysis of it?

A. No, I made no chemical analysis.

10323 Q. Who did make that?

A. I don't know; that is, I don't remember the man's name.

Q. Did you remove all of those sacs in the box at Robey street?

A. All the sacs that were removed, I removed.

Q. Were they all removed that were placed in there?

A. They were.

Q. And you removed them all?

A. Yes, sir.

Q. How long until you removed the last sac?

A. The last sac was removed at the end of the experiment. The last sac was removed about the 10th of November.

Q. They were placed in there when?

A. The first sac was placed in there, I don't remember the date.

Q. Were all of these sacs intact when they were removed by you from the box?

A. No, they were not.

Q. How many of them were not, if you remember?

A. Well, there were several sacs which remained a matter of about 18 days, as I remember, that were perforated when removed.

Q. Several of those?

A. Yes, sir.

10324 Q. Could you tell how long they had been perforated, Mr. Irons?

A. Indirectly, I could. By judging from the other sacs which I examined that were not perforated, at different periods of time.

Q. Then how long had these been perforated, if you can determine it indirectly?

A. I should judge that the sacs remained intact about on an average of about 17 days.

Q. While these sacs were in the canal, you spoke about a string being attached to them by means of which you would agitate them, what was the purpose of that?

A. The purpose of the string?

Q. Of the agitation?

A. At the time of taking samples, it was decided that the sample should represent the contents of the entire sac, and the agitation was used in order to completely mix the contents of the sac, so that the sample should be a fair sample.

Q. That was done only at times when you took the samples from the particular sac, was it?

A. Yes, sir; or at times when it was decided to inspect the sac possibly without taking samples.

Q. Could you not have inspected the sac without agitating it?

A. It would have to be agitated to some extent,
10325 because it would be impossible to see the sac in the water.

Q. Did you put this typhoid culture in the sac?

A. I did.

Q. Where did you procure that?

A. From Dr. Rosenow.

Q. You simply acted on his statements about where he obtained that culture, you knew nothing about that of your own personal knowledge, did you, Mr. Irons?

A. No, I know nothing except that I obtained the culture from him.

Q. And acted upon what he said, about where he obtained it?

A. Yes, sir.

Q. These bottles that you put your samples in, were they sealed, hermetically sealed?

A. The samples from the sacs were collected in sterile glass stoppered bottles containing about 75 c. c.

Q. And the bottles were sealed?

A. The bottles were sealed with a rubber cloth over the stopper, fastened by a rubber band around the neck of the bottle.

Q. Referring to that agitation again, Mr. Irons, would 10326 not the tendency be in shaking the sac in that manner, to shake down whatever might be attached to the sides of the sac, and it would fall to the bottom as a sediment, would that not be the natural tendency?

A. I do not think it would.

Q. Why would it not?

A. Because, if there is other sediment, by its nature, it will be found at the bottom of the sac, if it is present at all, so that in order to examine that fluid, we agitated it.

Q. Then, anything on the side, or in the bottom, would appear in a liquid?

A. Anything lodging of such a nature, that could float off in the agitation, would appear in the liquid.

Signature waived. F. S. B., Com'r.

10327 MARY C. LINCOLN,

a witness called in behalf of the defendant, having first been duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Mr. Todd.

Q. What is your name?

A. Mary C. Lincoln.

Q. What is your business?

A. Bacteriologist.

Q. Where are you employed?

A. I am employed at the Food Preservaline Company, M. Cohen Brothers.

Q. Chicago, Illinois?

A. Chicago, Illinois.

Q. Did you do any work under Prof. Jordan at the Chicago University, in connection with an experiment made by him on the waters of the Drainage Canal for the Sanitary District of Chicago?

A. I did.

Q. In what capacity were you then engaged?

A. As an assistant doing the laboratory work.

Q. Did you receive the samples that were brought into the the laboratory by Mr. Irons?

A. I did.

Q. And what was done with these samples when they were brought into the laboratory?

A. They were plated by me.

Q. Was the work which you did in connection with these samples done under the direction and supervision of

10328 Prof. Jordan?

A. It was.

Q. This was his private laboratory in which you were engaged?

A. Private laboratory.

Q. And the results of that work was tabulated by him in the tables that have been introduced here in evidence?

A. It was.

CROSS EXAMINATION BY
Mr. Corum.

Q. Did you have anything to do with picking off the typhoid colony?

A. I did.

Q. Did any one assist you in that?

A. Only Dr. Jordan, and Mr. Irons twice, I think.

Signature waived. F. S. B., Com'r.

Adjourned until 2 p. m., same day.

10329 2 P. M. Monday, February 15, 1904. Continuation pursuant to adjournment. Present, the Commissioner, and same counsel representing the respective parties.

F. R. ZEIT,

recalled for further direct examination by Mr. Todd, testified as follows:

Q. Prof. Zeit, since you gave your testimony in this case, last October, have you made any experiment upon the longevity of the typhoid bacillus?

A. I have.

Q. Was this experiment made by yourself, or in conjunction with some one else?

A. It was made in conjunction with Prof. Jordan and Prof. Russell.

Q. Will you state the general plan as outlined for the making of this experiment?

A. The plan outlined was that Prof. Jordan should determine the longevity of typhoid bacilli under the most natural conditions, as would obtain in the drainage canál, both at the beginning of the drainage canal and at its end, and that Prof. Russell was to determine the same question with regard
10330 to the longevity of the typhoid bacillus at Averyville
and that I was to determine the same question in Lake Michigan water, and in the Chicago River.

Q. Did any one assist you in this work?

A. Yes sir, my assistants Dr. Bassett and Dr. West. Dr. Bassett is an assistant and instructor in bacteriology at the Northwestern University Medical School, and Dr. West is my assistant at the Post-Graduate Medical School.

Q. After the stations at which each of you were to do your respective work were selected, what were the general plans which you adopted in carrying on this experiment?

A. I adopted two plans, the first was to use parchment sacs, the second plan was to use celloidin sacs, both intended to allow osmosis, and both to contain the typhoid bacillus in the presense of the normal saprophytes present in the water of Lake Michigan, and the Chicago River.

Q. Will you describe the characteristics of the parchment sacs and the celloidin sacs for the purposes for which they were used in these experiments?

A. Both allow osmosis to take place the parchment sac as well as the celloidin sac. The only object of using them was to allow the saprophytic bacteria in the sacs to multiply 10331 without retaining their excretions in the sacs which might destroy the typhoid bacillus. In this way, there was a free interchange between the excretions of bacteria imprisoned in the sacs, as well as the products of micro-organisms in the free waters of the Lake, as well as the Chicago River.

The principal object was to allow free interchange and to have the conditions in the sac the same that they were outside of the sac, with the one exception that, inside of the sacs there were, besides the usual water bacteria and saprophytes, also typhoid bacilli.

Q. How were these parchment sacs and celloidin sacs prepared?

A. Parchment sacs of a size to contain about 1000 cc. of water were folded at one end twice, and then also folded lengthwise, at the upper end around a glass tube and then tied with a string, after which they were, the folds and string were covered with a mixture of sealing wax, tallow and rosin. In the upper end was inserted a glass tube of the size of about ten mm. which was tied in with a string and sealed with sealing wax, tallow and rosin.

The celloidin sacs were prepared from what is known as Park Davis's Veterinary Capsules, No. 00. These are 10332 made of gelatin, and into each capsule was inserted a glass tube of a diameter of about 5 mm. Then the capsule, which contained 30 cc. of water, was coated over with 6 % celloidin solution. A number of coats of this solution were applied, always allowing drying between each application, and then the sac was filled with water and the gelatin inside allowed to dissolve with heat. It was then repeatedly washed out, so that finally only the celloidin sac together with the glass tube was left. Both kinds of sacs, the parchment sacs as well as the celloidin sacs were tested. We tested them by first blowing into them, the sacs being under water, and looking for air bubbles. Second, we tested them by introducing an albumen solution into the sack and then testing the outside fluid in which they were suspended for 24 hours, for albumen. If these tests were negative the sacs were considered satisfactory and they were used in the experiment.

The sacs were sterilized before use whenever we inoculated the boiled water of Lake Michigan, or boiled Chicago River water with typhoid bacilli. We did this in order to see how long a typhoid bacillus could live if other bacteria were killed 10333 by boiling bacteria normally present in the Lake Michigan water, or in the Chicago river water, were present. The principal experiments that were made were, however, always made by filling the sacs, both parchment and celloidin sacs, with the Chicago river water, or Lake Michigan water, and then inoculating the non-boiled raw water with typhoid bacilli about on an average of 500,000 to the cc. of water in the sac, and then suspending all these sacs in the water according to what water was in the sac. If it was Chicago river water, why, then the sacs would be suspended in a box, and if it was Lake Michigan water, the sacs were suspended in a jar in my laboratory at the Post-Graduate Medical School.

Q. After these sacs were prepared, tested and sterilized in the manner that you have indicated, what method did you pursue in infecting the sacs with typhoid bacilli?

A. The sacs were inoculated with typhoid bacilli which had grown upon agar slants, for 24 hours in the incubator. Of these, coli grown on agar slants enough material was placed into the sac to produce a mixture of about 500,000 typhoid bacilli to the cc. of the water.

Q. Where did you get the cultures of the typhoid fever germs that you planted on the agar slant?

A. We received one strain of typhoid bacillus from Prof. Jordan marked "Bacillus X." These bacilli were obtained from the blood of a typhoid fever patient at the Cook County hospital. The other bacillus we received from Parke, Davis & Co., in Detroit. This bacillus had been used to immunize a horse. With this bacillus we also received the serum of the immunized horse.

Q. After these cultures of bacilli were received by you, what did you do with them?

A. We inoculated many other agar tubes from them, and put them in the incubator over night, and these were the cultures which we used.

Q. After your culture was prepared, what method did you employ for infecting the sacs of parchment and celloidin that you prepared?

A. We suspended these sacs in the Chicago River at the Ashland avenue bridge in a box, and similar sacs were suspended in a jar of water through which fresh Lake Michigan tap water was constantly flowing. At the time they were suspended in these two localities, we plated out upon agar, and, from now on we plated out every day from these sacs which we had 10334 in the Chicago River, and in the laboratory with the tap water, and made agar plates. We made agar plates every day, from both Lake Michigan and also river water, from these sacs.

Q. Will you describe the boxes into which these sacs were suspended?

A. The boxes were prepared in the same manner as Prof. Jordan prepared his. The boxes were suspended in the same manner except that we had inside of the box a cross piece on which were fastened a number of burette clamps into which the glass tubes of the parchment sacs were clamped, the sac being suspended in the water. The celloidin sacs were suspended in the same manner, the open tube closed with cotton, the same as in the parchment sacs and passing out for some distance above the outside water.

Q. What was the purpose of the cotton?

A. The purpose of the cotton was principally to prevent the entrance of other bacteria except those in the water, and second, to allow free access of air. It acts as a germ filter, but does not prevent the entrance of air.

Q. How were the sacs which you have described, infected with the typhoid bacillus that you had prepared?

10335 A. In the parchment sacs we took a suspension of typhoid bacilli in sterile water made by distributing material from colonies grown upon the agar slants for 24 hours. We took these watery suspensions of typhoid bacilli to the Ashland Avenue bridge. The sacs were suspended in the box in the river, under the south side of the bridge. We filled the sacs, first with river water, and then added to the 800 cc. of river water enough of our watery suspension of typhoid bacilli to make in the sac a mixture containing between 200,000 to 1,500,000 typhoid bacilli per cc. We made these experiments numerous times. We used an average suspension of 500,000 typhoid bacilli to the cc. in the sac.

Q. After these sacs were infected in the manner that you have indicated, what was the next step pursued by you in the experiment?

A. We would plate out at once and then go there the next day and remove from the parchment sac by means of a sterile pipette a quantity of the water in the sac after the sac had been shaken. We would always first loosen the burrette clamps, take out the whole sac and see whether it was still patent, and that there was no leak. If there was no leak, we would shake the sac and then remove by means of a sterile pipette, a quantity of water which was placed into a sterile flask which we had 10336 brought along. This flask was immediately taken to the laboratory and here plated out. We would plate out on agar, and we would use for each agar plate .001 cc, .01 cc, .1 and 1 cc, and sometimes larger quantities, as much as 5 cc.

Q. How soon after the sacs were suspended in the drainage canal at Ashland avenue would it be before the samples were taken out in the manner you have just indicated?

A. The first samples were usually taken after 24 hours and after that, daily. We took one sample a day from the moment that we placed the sacs in the river.

Q. Who placed these sacs in the river?

A. Dr. Bassett and myself.

Q. You had personal supervision of this experiment?

A. I did.

Q. And all parts of it?

A. And all parts of it.

Q. Confining yourself now to the experiment at Ashland avenue, how many sacs of parchment and celloidin were placed in the Chicago river at that point by you?

A. There were 8 experiments made at each place, that is, eight experiments at the Ashland avenue bridge in the river water, and 8 experiments made in flowing lake water from the tap of the Post Graduate laboratory.

10337 Q. How many of these 8 sacs at Ashland avenue which you employed in this experiment were celloidin, and how many were parchment?

A. There is some difference between those experiments. In the case of parchment sacs we filled each sac only once, and would take samples daily from the sac. In the celloidin sack experiment we used very many sacs, and took out a whole sac every day and took it to the laboratory. We never took any samples of water out of the celloidin sacs in the river but always took a whole sac. We would take for one experiment as many as 8 or 10 celloidin sacs to the river filled and infect them and suspend them all, and bring home one of these sacs every day, and plate out from it at the laboratory. In other words, we avoided any possible contamination of the specimens to be plated out, and used 8 to 10 celloidin sacs for one experiment, whereas, with the parchment sacs, one sac always made one experiment and we would take out 25-30 CC water from that, daily.

Q. Now, professor, will you explain in detail the definite means employed, the manner in which they were employed, in making the experiment at Ashland avenue?

A. After the parchment sacs were filled and infected with the suspension of typhoid bacilli that we had taken to the place, we then took from the mixture a specimen of water from
10338 the sac into a sterile flask and took that home to the laboratory for control. The next day, and every day following, Dr. Bassett would go to the box and obtain from this sac a quantity of the fluid after examining the sac for holes, nd bring this material in a sterile flask to the laboratory. At he laboratory every day, then, we would plate out this material n a number of plates, using .001; 0.01; .1; 1 cc, and someimes more of this water from the parchment sac. Common gar was used. The agar plates, which were placed into the ncubator over night, were then examined from day to day and ny typhoid like colonies were inoculated into Hiss's medium. This was done for several days, the colonies which in Hiss's ledium proved to be non-motile bacteria, or which proved to e gas producers were thrown aside. Only those colonies in iss's medium which showed no gas but showed a diffuse oudiness due to the motility of the organism that had been

growing there, were then tested with the serum obtained from Parke, Davis & Co. of the immunized horse which would agglutinate typhoid bacilli in a dilution of 1 to 1000, almost instantly. If by this test we found that such a colony was
10339 a typhoid bacillus, we would take it for granted that the typhoid bacillus was still present. When it was impossible to get any positive Widal serum reactions by this means, then we would take that plate in which we were unable to find typhoid bacilli and inoculate from it Hiss's tubes, taking every colony that had grown on it. Then, again, from Hiss's Medium, we would pick out the motile, non gas producers and make a Widal serum test. We would sometimes, also use Litmus milk.

Q. Professor, will you explain the bacteriological significance of the strain of the typhoid bacillus which you used together with the significance and meaning from a scientific standpoint of the serum of the horse, which you employed in this experiment?

A. The object of using preferably the Parke, Davis bacillus "O" was to enable us by means of the Widal test to quickly find colonies of typhoid bacilli if present. In other words, we avoid very much labor in the way of running the colonies
10340 through so many different culture media. We could tell the typhoid bacillus sometimes almost immediately. We could tell it sometimes directly on the plate. I have taken agar plates after they had been in the incubator and right away picked up a typhoid like colony and tested it with the serum of the immunized horse. The reason we preferred this bacillus to the "X" bacillus was because we could do so much more work. We could examine so many more colonies and we would find typhoid bacilli much quicker. We would avoid a great deal of troublesome examination. When we were satisfied that we had a Widal reaction in the dilution of 1 to 1000, we put that down as positive that the typhoid bacillus was present.

The whole method of diagnosis of a typhoid bacillus, that is the most certain and acceptable one is that of being able to agglutinate typhoid bacilli by certain substances which are present in the serum or in the blood of the person who has typhoid fever, or the immunized animal which has been injected with typhoid bacilli. If an animal is injected with typhoid bacilli in a less dose than that which would kill it, the result is that a substance is produced in the animal's serum which agglutinates typhoid bacilli, which clumps them.

10341 The typhoid bacillus is normally a very motile and active bacillus, but when small traces of the serum of an immunized horse or the serum of a typhoid fever case is added to a watery suspension or the fresh bolliuon culture of motile typhoid bacilli, they lose their motility and aggregate in clumps. This constitutes one of the essential points of diagnosis and therefore we preferred to use the Parke Davis bacillus in most of our experiments.

Q. What relations existed between the strain of typhoid bacillus that you used, and the serum of the immunized horse which you used?

A. It was the homologous germ. It was the germ which had been used for immunizing the horse, and therefore the test was more to be depended upon than if we had used the serum of a typhoid fever patient which had been infected with another strain of typhoid bacillus.

Q. Where did you secure the serum which you used, and how did you get it?

A. We received both the typhoid bacillus with which this horse had been immunized as well as the serum of the immunized horse at the same time from Dr. Larned, the Chicago representative of Parke Davis Co. who had told me that they had an immunized horse whose serum would agglutinate the homologous germ in the dilution of 1 to 50,000, or 1 to
10342 60,000.

We found, however, that it would agglutinate it only in 1 to 1000.

Q. What other strain of typhoid did you use in the experiment, or at Ashland avenue, in the Chicago river?

A. We used a strain received of Prof. Jordan's laboratory, typhoid bacillus "X," which was obtained from the Cook County Hospital from the blood of a patient having typhoid fever.

Q. Will you describe the part of the experiment conducted at Ashland avenue with the celloidin sacs?

A. We would take from 8 to 10 celloidin sacs for one experiment to the Ashland avenue bridge together with suspensions of typhoid bacilli in water, which had been grown on agar in the incubator over night, and would then fill all the sacs by

removing the cotton stopper and placing the sacs under water. We would not entirely fill these. We would pour out some of the sacs and we would then infect them with our suspension, to a number of 500,000 typhoid bacilli per 1 cc and then insert the cotton stopper, place their glass tubes into the burrette clamps, suspended in the water, only the glass tubes
10343 sticking out, and we would remove one sac and take it to the laboratory every day, and proceed in the same manner of plating out and differentiating, as we did with the water specimen of the parchment sacs.

Q. What strains of typhoid fever did you employ in these celloidin sacs?

A. In the celloidin sacs we only used the Parke Davis strain.

Q. In the parchment sac?

A. In the parchment sac we used both strains, the bacillus X of Prof. Jordan and the Parke Davis bacillus.

Q. Were these mixed together in the parchment sac?

A. They were not. We either used the one or the other.

Q. How many parchment sacs did you use at Ashland avenue?

A. Six.

Q. How many celloidin sacs did you use at Ashland avenue?

A. 16 to 20, I should say, because some broke. We took 10. We usually took 10, but some accident would occur once in a while. We intended to have 10, and take one out every day after we knew how long the typhoid bacilli lived at Ashland avenue bridge, by the parchment sac experiment. We took 10 sacs of celloidin for one experiment knowing that we would not find them any longer than ten days, but usually some of
10344 them would break, so that probably we had 16 to 18 sacs in all, suspended.

Q. How would this breakage occur?

A. This breakage would occur by dropping one and breaking the glass upon the stone foundation of the bridge. The whole danger of breaking existing at the time that we put them in, not at the time that we took them out, and if one sac would drop, then why, the glass tube which was very long, was broken. We could not use that tube. It was not the sac that broke. The to use the parchment sacs longer than 10 days. That is also the reason why we used the celloidin sacs only 10 days. Feeling certain that we had examined every colony on the plates in one of the first experiments after typhoid bacilli could not be found any more and that the results were negative after 3 days, we thought that 10 days was all that was necessary to follow up the experiment on an average in future experiments.

Q. Have you stated everything connected with the Ashland avenue experiment, now?

A. No, I have not. We have also made experiments in which we have taken the river water and filtered it through a Pasteur filter and then have plated it out to make certain that no water bacteria had passed through the filter. Such raw, filtered river water we infected with typhoid bacilli and found that typhoid bacilli die in this water also in two days, in 10349 some instances, so that it would appear that there is in the water itself something which destroys typhoid bacilli even if no saprophytes are mixed with typhoid bacilli. The reason I mention this is because in some of my former testimony, I laid particular stress upon the fact that I thought the disappearance of the typhoid bacillus in the experiments reported at that time was principally due to the overgrowth of saprophytic bacteria, whereas, as a result of these experiments, I conclude that there are in this river water certain substances, possibly excreted substances of saprophytes, which alone are sufficient to prevent the growth of the typhoid bacillus and even to destroy it within a very short time.

We have also made experiments in which we inoculated a typhoid bacillus into boiled river water. And in these experiments the bacillus lives longer than it did in the raw but filtered river water. In boiled river water containing no living bacteria, into which we inoculated typhoid bacilli, they would live longer than they would in the unboiled, filtered sterile river water.

10350 Q. How much longer, Professor?

A. Three days longer.

Q. In the boiled filtered water?

A. Yes sir.

Q. How long did they live in the parchment sacs and the celloidin sacs which you employed at Ashland avenue?

A. The longest was three days. There is not so much difference between the presence of saprophytes in the sacs and the effect of raw filtered water on typhoid bacilli.

Q. Did you make any other experiments in conjunction with this experiment?

A. I made, in one instance, an experiment by which I added to the water from a parchment sac, immune serum of this horse, and then collected the preciptate in the form of a conical glass tube and added peptone solution to this precipitate, hoping that if I had escaped any typhoid bacilli by the other method, this way I could enrich the number of typhoid bacilli, if any had been left alive. I tried this several times, always adding again serum of the immune horse in that way, hoping to agglutinate and precipitate the typhoid bacilli of the whole quantity of water used, and in that way obtaining all the typhoid bacilli that were present in the water, and getting it to the bot-
10351 tom, pouring off the rest and adding nutrient material to the residue because it is a fact that immune serum agglutinates typhoid bacilli, but will not kill them. So I thought if I used large quantities of the water I might be enabled to find typhoid bacilli later than in the other experiments, where only small quantities of water are used for plating out. I was entirely unsuccessful here in finding typhoid bacilli probably because these experiments were only made after the other experiments showed the disappearance of typhoid bacilli. I am convinced the method is a good one and will enable us to find typhoid bacilli if they are there, much easier because we can use a larger quantity of water for this test. If we have enough serum, we can agglutinate all the typhoid bacilli and they fall to the bottom and can be grown again on plates because the precipitated clumps of typhoid bacilli are not dead.

I was unsuccessful, after the third day, in the river water, by this method, to find any typhoid bacilli.

10352 Q. Did you employ that method before the third day?

A. I experimented on it before I employed it. I added a very small loop full of bouillon culture to a liter flask of water, and of this liter flask full of water took one loop full and added it to another liter glass full of sterile water, and tried the experiment upon this dilution in the second flask and had no trouble in finding typhoid bacilli.

Q. How many cc in a liter?

A. 1000.

Q. What success did you have in agglutinating the X strain sent to you by Prof. Jordan, with the horse serum?

A. That agglutinated, although not in as great dilutions. The best that we could do was to agglutinate a dilution of 1 to 30 or 1 to 40. We also inoculated a few rabbits with this bacillus, the serum of the animals which lived never agglutinated the same bacillus X, in a greater dilution than 1 to 50, or 1 to 100. Feeling that the Widal test was such an important one in our work for the identification of the typhoid bacillus, we preferred to use the Parke Davis culture mostly.

Q. How did the Parke Davis culture compare in vitality with the X strain? 10353

A. The vitality was just as great if not greater. It was more motile than the bacillus "X." It was a great deal more motile than the bacillus X.

Q. In making this experiment at Ashland Avenue how comprehensive was it as far as the known methods of bacteriology for the determination of typhoid in the water was concerned?

A. I would say that the manner employed here of using a membrane that allowed osmosis of the fluids outside of the sac in the river as well as the excretions of the bacteria multiplying inside of the sac to pass freely in and out, conditions were produced which were as nearly those existing in nature as could be artificially produced. This experiment shed more light upon the true conditions of the longevity of a typhoid bacillus in polluted streams than we have known in the past. The opinions of bacteriologists the world over have varied as to the length of time that a typhoid bacillus would live in lake and river waters and I am satisfied now that this variation in their statements as to its longevity is not due so much to the varying vitality of the typhoid bacillus as to the presence in the water of certain substances which in one case will destroy a typhoid bacillus quicker than in another. 10354 I think that these variations can only be explained by such experiments as we have made. The fact that even in the raw filtered river water, free of all saprophytes typhoid bacilli die rapidly is evidence that there is in this water something which destroys the typhoid bacillus quickly. That effect must vary in different rivers, and such variation is due to the greater or lesser presence of substances excreted by saprophytes which explains the greatly varying statements of different authors.

Q. Professor, will you explain in full the experiments which you conducted with Lake Michigan water?

A. With Lake Michigan water we used parchment sacs and also celloidin sacs. The parchment sacs were filled with Lake Michigan water from a tap at my private laboratory at the Post Graduate Medical School, second floor. The infection of the sacs with typhoid bacillus, first the X bacillus, afterwards the Parke Davis Bacillus, was done exactly in the same manner as those in the Chicago River. The sacs were then suspended in a large earthenware jar by burrette clamps, in the same manner as in the river. The sacs were prepared in exactly the same manner and the water from the tap was, by means of a
10355 large rubber tube, allowed to flow day and night, the tube extending to the bottom of the earthenware jar, and the fluid overflowing the top of the jar, so that at all times fresh tap water was flowing through the jar, on the outside of the sacs. After the sacs were placed, small quantities of water were removed from the sacs daily, after removing the sac and testing it for holes, and then shaking the sac. The mixture from the sac was plated out in agar, using for the agar plates .001, .01, .1, 1, 2, 3, and 5 cc. daily. The colonies that appeared upon this agar in the incubator were inoculated into Hiss media. The number of colonies sometimes was very small and every colony on the plates was inoculated into Hiss media.

During the first four or five days we would usually succeed in picking out a typhoid suspicious colony from one of these plates, which immediately gave a Widal test, so that would be set aside. The longest that we found typhoid bacilli here was for 8 days. At the time when they disappeared on the ninth day we would take every colony on all the plates and inoculate every one into Hiss tubes. This was repeated several times to get all the colonies and pass them all through Hiss meria and
10356 then only those which showed motility in Hiss media and which produced no gas were then passed through the usual culture media and were tested with the immune serum.

The longest that we found typhoid bacilli was 8 days. Sometimes we did not find any after 4 days.

Q. Did you employ the celloidin sacs in this experiment?

A. The celloidin sacs were also used. We used possibly some 30 celloidin sacs with lake water and took one celloidin sac out every day.

Q. When you speak of one experiment with the celloidin sacs does that experiment embrace a series of 10 celloidin sacs that were inoculated to the same degree of infection with typhoid bacillus in which you took one of those sacs each day?

A. In the case of Lake Michigan water the series of sacs usually consisted of 15, in some of these experiments for 15 days, once for 20 days. The 20 days was parchment. When I say 30 sacs with the celloidin experiments I mean 2 complete series
of experiments of 15 sacs each. We made six parchment
10357 sac experiments, but one sac broke in taking it out. So
there are two completed experiments with celloidin sacs and five completed experiments with the parchment sacs.

Q. In the waters of Lake Michigan?

A. In the waters of Lake Michigan—tap water.

Q. Did you make any other experiments in conjunction with this experiment in Lake Michigan?

A. We also here inoculated sterilized Lake Michigan water in sacs with typhoid bacilli, and these lived 10 days longer than in raw filtered lake water. They varied a little.

Q. What other experiments did you make?

A. That is all.

Q. What were the results obtained in the experiment of Lake water that you have detailed?

A. In the lake water the typhoid bacillus lived at the longest 8 days, when mixed with the unsterilized lake water. At times we were unable to find the bacillus after the 4th day.

Q. How near in your opinion does the experiment made by you yourself simulate natural conditions?

A. The conditions are as close to natural conditions as it is possible to make them.

10358 Q. Were the conditions of the experiment which you
[illegible]ve introduced more or less favorable to the longevity of the typhoid bacillus than the natural conditions of the water in which the experiment was made would be?

A. I do not think that there is much difference between the conditions in the sac and the conditions outside.

Q. What reasons have you for supposing that the conditions described in your experiment closely simulate natural conditions.

A. Because the surroundings of the typhoid bacillus in the river are the same as those in the sac, by osmosis of the different fluids, and as I have already stated before the principal cause of the death of the typhoid bacillus in water is evidently the presence of some saprophytic products which are outside of the sac just in as large a quantity as inside of the sac, and if there existed any difference these differences would be quickly equalized by osmosis.

Q. Professor, does this experiment which you have made and introduced furnish you with any basis for an opinion as to the life of the typhoid bacillus in the waters of the Chicago River and Drainage Canal and Illinois River?

A. Yes sir. As a result of the experiments which have
10359 been made by all of us, Professor Jordan, Professor
Russell and myself, I am of the opinion that typhoid bacilli can not live in the drainage canal or in the Chicago River or the Illinois River for more than three days.

Q. What is your opinion, based upon all the knowledge which you possess in regard to this experiment, and other experiments made by you, as to whether the typhoid bacilli coming from the sewers of Chicago and entering the drainage canal and from thence into the Illinois River could survive the journey from Chicago to St. Louis, a distance of 357 miles, and be a danger and a menace to the inhabitants of St. Louis using the waters of the Mississippi River at the St. Louis intake, or the residents of Missouri using the waters of the Mississippi River, as it passes along the eastern shore of the State of Missouri, for domestic and drinking purposes?

A. It is my opinion that it offers absolutely no danger to the citizens of St. Louis and that no typhoid bacillus coming from the sewers of Chicago will live to reach there.

Adjourned until 10:00 A. M., Tuesday, February 16, 1904.

10360 10:00 A. M., Tuesday, February 16, 1904. Continuation pursuant to adjournment. Present the Commissioner and same counsel representing the respective parties.

DR. EDWIN C. ROSENOW,

a witness called in behalf of the defendant, having first been duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION by Mr. Todd.

Q. What is you name?

A. Edwin C. Rosenow.

Q. Of what college are you a graduate?

A. Rush Medical College.

Q. When did you graduate from Rush?

A. 1902.

Q. Where do you live, Doctor?

A. Presbyterian Hospital, Chicago.

Q. What business are you in at present?

A. I am an interne at the Presbyterian Hospital.

Q. Before becoming connected with the Presbyterian Hospital were you connected with any other hospital?

A. Why, in a way, I was only secondarily connected, as 10361 Fellow at Rush Medical College in pathology.

Q. Professor Jordan has testified in this case to having received three strains of the bacillus typhosus from you, to be used in the experiments which he made on the life of that organism in the drainage canal. When did you give him those typhoid bacilli?

A. Why, I don't remember the exact date. I have notes that would give the exact date.

Q. About when?

A. Some time last September.

Q. Where did you get them from?

A. I got them from three cases of typhoid fever in the Cook County Hospital.

Q. Did you give to Professor Jordan a clinical diagnosis of the patients from whom these germs were taken?

A. You mean the diagnosis or history?

Q. Yes sir?

A. Why, I copied the history of these three cases of undoubted typhoid fever and handed them to Mr. Irons, who in turn was to hand them to Professor Jordan.

Q. You have heard read the diagnosis of the three patients from whom typhoid bacilli were taken by yourself 10362 and handed to Mr. Irons and Professor Jordan, as testified to by Professor Jordan in his testimony in this case. Are you the doctor who collected these samples?

A. Yes sir.

Q. Are the statements that I have read to you from Professor Jordan's testimony as to the clinical history and diagnosis of these cases the correct history and diagnosis that you gave to Professor Jordan with the samples that you collected?

A. Yes sir.

Q. Doctor, state how these samples were collected from these three patients?

A. Why, the blood of the first patient was collected as given in there, from the medium bacillic vein of the arm with a glass syringe, in a sterile manner. The blood was then used to inoculate the various media from which the typhoid bacillus was isoluated in pure culture. The urine from the second case was collected in a sterile bottle of about the size of 10 ounces. That urine was taken to the laboratory by myself and the various inoculations made from which the typhoid bacillus was isolated and the feces were collected from a sterile bed pan, into a sterile test tube, and also taken to the laboratory and 10363 the inoculations made at once.

Q. And after the typhoid bacillus was separated from these three patients, what did you do with the typhoid bacillus?

A. After proving and testing it every way as being typhoid bacillus, I handed them to Professor Irons.

NO CROSS-EXAMINATION.

Signature waived. F. S. B. Com'r.

10364

PROF. F. R. ZEIT

resumed the stand for further re-direct examination by Mr. Todd, and testified as follows:

Q. Professor, upon examining your testimony that was given yesterday, I find that you did not state the size of these parchment sacs or celloidin sacs that you employed in this experiment. Will you please state how large they were?

A. The parchment sac was of a size to contain 1000 cc of water. The celloidin sac was of a size to contain 30 cc. of water. The measurements of a parchemnt sac were 24 inches by 3 inches. The size of the celloidin sac is about 3 inches by 1 inch.

Q. Professor, as an expert in bacteriology and clinician, availing yourself of all bacterial knowledge which you possess based upon this experiment, as well as knowledge obtained from other sources, what is your opinion as to whether a typhoid bacillus, lying in the sediment of a polluted stream such as the Illinois River, for a period in excess of 60 days would be able to cause typhoid fever when taken into the human system after it had remained in such sediment for that length of time?

A. It is my opinion that after that length of time there would be no typhoid bacilli present any more. The conditions existing in material on the bottom of rivers and lakes 10365 by sedimentation must contain organic material and saprophytic bacteria which again would produce substances that would destroy the typhoid bacillus if it was present in just as quick a manner as they do in the river or lake water. In fact I should think that being so much closer in contact with the saprophytic bacteria in the presence of organic material that the quantity of these poisonous substances produced by saprophytes would be even greater and cause typhoid bacilli to die at least as quick if not quicker under these conditions than in flowing water.

Q. What is your opinion as a bacteriologist and pathologist as to whether typhoid bacilli coming from the sewers of Chicago, through the drainage canal, deposited on the bottom of the Desplaines and Illinois Rivers between Chicago and Peoria can remain there for a period of 30 to 60 days and yet retain their dangerous qualities as well as their pathogenesis?

A. By what I have learned from the experiments that we have made, that is impossible. Typhoid bacilli die under those conditions in three days.

Q. From your personal knowledge of the Illinois River 10366 and your knowledge as a bacteriologist and pathologist, together with all bacterial knowledge which you possess, derived from every source, what is your opinion as to whether the sewage from the City of Chicago, passing through the drainage canal into the Illinois River at different seasons of the year and at different stages of water in the Illinois River, would be a danger and a menace to the inhabitants of the State of Missouri using the waters of the Mississippi River for drinking and domestic purposes, and to the citizens of the City of St. Louis in particular using the water of the Mississippi River at the intake tower at the chain of rocks for drinking and domestic purposes?

A. It is my opinion that they would never reach the intake of St. Louis alive, because it has been proven by our experiments that they die in three days or less in the water of the drainage canal and the Illinois River, so that they could never reach the lower course of the Illinois River even.

Q. What is your opinion as a bateriologist, based upon your examinations of the waters of the Illinois, Mississippi and Missouri Rivers as to which one of these three rivers disclose the least amount of impurity of pollution?

10367 A. The Illinois River, bacterially speaking, was less polluted during my investigations than either the Missouri or Mississippi. During all of my examinations in the past that has been the case.

Q. If the Illinois River discloses from such examinations made by you the least amount of impurity, what would be the effect of the waters of the Illinois River emptying into the Mississippi River at Grafton and subsequently uniting with the Missouri River at its mouth, upon the united waters of the Mississippi and Missouri Rivers at the intake tower of the chain of rocks?

A. As the Illinois River is bacterially purer than the Mississippi River it could only improve conditions by dilution.

Q. Does the mixture of the Illinois with the Mississippi and Missouri Rivers, as indicated in the foregoing question, create any added danger to the already polluted and contaminated waters of the Missouri and Mississippi River below Grafton?

A. It does not, in my opinion. The very reverse would be true, according to my former answer.

Q. Do you consider the sewage of Chicago emptying into

the drainage canal and the Illinois River, which in turn empties into the Mississippi River, a menace and a danger to the inhabitants of the State of Missouri, using the waters of the
10368 Mississippi River for drinking and domestic purposes and to the citizens of the City of St. Louis taking their water supply from the intake tower at the chain of rocks, from the Mississippi River?

A. I do not for the reasons stated in my former examinations, in which I stated that the Illinois River at Averyville was purer, bacterially, than any part of its course from Chicago to Grafton, and that I considered that absolute purification from saprophytic as well as pathogenic bacteria had taken place above Averyville.

Q. Taking into consideration all the knowledge which you possess in regard to the bacterial and physical conditions of the waters of the Illinois River and its tributaries and the river itself, the different towns sewering into the Illinois River and its tributaries, the population upon the watershed of the Illinois River, both rural and urban, the stages of the river under all conditions, during all seasons, what is your opinion as to the effect of flowing the sewage from Chicago through the drainage canal into the Desplaines and Illinois River, upon the inhabitants of the State of Missouri, using the water of the Mississippi River for drinking and domestic purposes?

10369 A. The contamination produced by the sewage of Chicago would be all practically removed before it reaches Averyville, according to my investigations and answers in this case, in which I have expressed these convictions at some length. I am speaking now, of course, of bacterial purification and not of chemical substances, but I should judge that also chemical purification has taken place so as to convert dangerous organic compounds into non-dangerous ones, as soon as saprophytic life has again decreased and thereby shows that the end products of organic material have been produced by saprophytic multiplication, and I therefore can not consider this a danger or a menace to the citizens of St. Louis or the citizens of Missouri using the water for drinking and domestic purposes.

CROSS-EXAMINATION

By Mr. Corum.

Q. Professor, your experiments consisted in placing these sacks, the parchment and celloidin sacks in the waters of the drainage canal and in the waters of the lake?

10370 A. Yes sir, in the case of lake water we used tap water which was kept flowing continually. The other experiments were made in the Chicago River.

Q. That tap water came from the lake?

A. Yes.

Q. And you did not place any of these sacks in the Illinois River?

A. I did not.

Q. Or in the Mississippi River?

A. I did not.

Q. The only two waters in which these sacks were placed by you were the waters of the canal and the waters of the lake?

A. No sir, in the water of the Chicago River just where the drainage canal begins at Ashland Avenue Bridge. That is still the Chicago River.

Q. How many sacks did you place in there near the Ashland Bridge?

A. Celloidin sacks?

Q. The celloidin sacks first?

A. We placed 6 parchment sacks in the river, and we placed between 16 and 20 celloidin sacks in the river.

Q. Now, who removed these parchment sacks from the river?

A. Dr. Bassett.

10371 Q. How soon after having placed them in there did he remove the first one?

A. 24 hours.

Q. Do you know what course he pursued in removing the sacs?

A. He would loosen the burette clamp, take hold of the glass tube at the top of the parchment sack, lift it out, examine it for leaks after holding it a while, then shaking it and then replacing it. After removing the cotton stopper, he took out, by means of a sterile pipette a quantity of water, placed it in a sterile flask that he had brought with him, replaced the cotton stopper, and brought it immediately to the laboratory and plated it out.

Q. Then he put this same sac back into the box again?

A. Immediately after he had inspected it and had shaken it, it was placed back.

Q. Did he take any further samples from that sac?

A. He took one sample each day from every sac?

Q. From each sac?

A. Yes sir, these sacs were not all put in at the same
10372 time. The celloidin sac experiments followed the parchment.

Q. We are talking about the parchment sac. During the examination of these samples which were removed from the parchment sacs on the first day you found some typhoid germs?

A. Yes sir.

Q. In each sample?

A. The first day we found always typhoid bacilli in the sacs.

Q. Did you examine each of the sacs?

A. In every sac we found them.

Q. On the second day did you find typhoid germs?

A. On the second day we sometimes found the germs and sometimes not. On the third day the same, we found sometimes germs and sometimes not. After the third day we were never able to find any more.

Q. On the first day did you find the germ in considerable amounts?

A. Yes sir, in large numbers.

Q. Have you any means of comparing the number that
1073 you found on the first day with the number that were in the sacs at the time you placed them there?

A. Yes sir.

Q. How was that comparison?

A. Dr. Bassett will be on the stand this afternoon and he has all the counts of every sac, and how many colonies there were. I am not reciting from memory and I should judge that there were about 500,000 of typhoid bacilli to the cc. of river water in the sac, that is every cc. contained a half a million typhoid bacilli, therefore we had no trobule in finding them the first day. When the sacs were seeded very lightly, that is much less than a half a million, we would occasionally find them gone the second day. I am speaking now of heavy seedings in all these experiments, because we found that that was necessary to judge as to when they were really gone.

Q. Suppose that in a certain sac that you found on an examination the second day that there were no typhoid germs in it? Then you examined that sac for the third day and found typhoid germs in it---how do you account for that?

A. That has never happened.

10374 Q. Did it not happen in one of your examinations that in an examination of the samples that were taken from a certain sac on a certain day you did not find any typhoid germs and afterwards, on the following day, or some day following that you would examine the same sac and find typhoid germs in it?

A. That has happened in none of our experiments, simply because when we thought that all typhoid bacilli were gone we would go back to that plate and go over it so thoroughly that we could usually say that we have examined every colony that had grown. We would sometimes find typhoid bacilli on the second day in a plate after we had been unsuccessful in the first attempt not having examined enough colonies. We can say that in no instance did we find typhoid bacilli after a day on which we found none, in our experiments. That holds good for all of them.

Q. After a day when you had examined to see whether there were any typhoid germs, would you take any samples after that?

A. We would take samples for ten days and more in some of the first experiments.

Q. And in no instance did you succeed in finding any germ?

A. In no instance. In the first experiment that we made 10375 we examined the contents of our parchment sac, the first sac that we used, for twenty days. That is when we were getting acquainted with the conditions necessary for the experiment and in that sac also typhoid bacilli had been seeded very heavily, over 1,000,000 per cc. They could only be found for three days. After the third day the whole character of the plate changed suddenly. For three days in succession we would have plates with numerous typhoid colonies, in this first sac, seeded very heavily with typhoid bacilli, and after the third day it was just as though normal water had been plated out. An entire change of the whole character of all the plates took place,

Q. Please state the reason for using the different kind of sacs?

A. The celloidin sacs, we felt, were safer to use. They had proven reliable in bacteriological animal experiments, in which for instance, we would take tetanus bacilli into a celloidin sac, close the sac and place it in the abdomen of an animal. The
animal would die of tetanus, although the bacteria re-
10376 mained in the sac. The bacilli would grow in the sac and
at no time in our laboratory experiments have we ever seen bacteria pass out of the sacs, but only toxic excretions of bacteria would pass out and produce convulsions. In that way we had in the past studied the effect of toxins removing from the experiment the effect that the germ itself might have, and it was principally due to the success of this method, that we used it also here with the water to allow osmosis.

Q. Why did you not use it exclusively?

A. The parchment sac was larger and we could make one sac do for a great many experiments. Cellodin sacs we could use only in smaller sizes, although we made them 20 times as large as they are usually made for animal experiments, by having these big verterinary gelatine capsules. We had to use 8 to 10 of these for one experiment, in the river removing one sac each day, because we could not very easily take water from these celloidin sacs. Now, in the laboratory experiments with lake tap water we did use some of the celloidin sacs several days because we were under less difficulties in removing portions of water from the delicate little sac, but in the river we found it was necessary to always take the complete sac home.

10377 Q. In the lake water I understand that at the expiration of ten days or eight days---

A. In the lake water the first experiment, both with lake water and with river water was 20 days and after that, when we found that bacteria died so much earlier, we would run the experiment 10 days and sometimes 15 days, but always ten days taking cultures every day.

Q. And how long did you find that the typhoid germ survived in the lake water?

A. In the lake water the longest time we found them was eight days. One time we thought we had found them on the ninth day, but further examination proved that this was wrong.

Q. Professor, you stated yesterday that you had found the typhoid germ to survive in boiled river water for the space of three days?

A. In boiled river water? You mean in filtered river water.

Q. I understood you to say boiled and also filtered?

A. No sir. In filtered river water I stated the germs live 2 days only, that is filtered through a Pasteur filter.

Q. How many days?

A. Two days. 2 days is the longest that they live in filtered river water. We have done that numerous times now and
some of the experiments in fact were finished yesterday
10378 and we know that the filtered river water as it exists now
will kill typhoid bacilli in two days, river water containing no bacteria whatever.

Q. I want you to explain the reason for the different length of life of the typhoid bacilli in boiled river water and in filtered river water?

A. Having proven that filtered river water, free of all germs, kills typhoid bacilli within two days, and also knowing that the boiling of such river water allows the same bacilli to live a longer time I conclude that by boiling you destroy certaind poisonous saprophytic products present in the water and that, therefore, in boiled river water the typhoid bacilli will live somewhat longer than they would in filtered river water. Under the same conditions in lake water typhoid bacilli will live eight days in the filtered lake water, and have lived fifteen
to eighteen days in the boiled lake water.

10379 Q. What property is taken from the water by the process of boiling that tends to add to the longevity of a typhoid bacillus?

A. I take it that the saprophytic products that destroy the typhoid bacilli are destroyed by boiling and that therefore the typhoid bacillus which enters boiled water can live longer than in water that has only been filtered, because the saprophytic products filter through the filter.

Q. Now Professor, are these saprophytic products to be found in the waters of the drainage canal?

A. They are.

Q. And in the waters of the Illinois?

A. And in the waters of the Illinois.

Q. Are they to be found in all waters?

A. They are to be found in all waters in which there is any pollution whatever. As soon as the water receives any organic material, such as sewage or other material, saprophytes begin to multiply in the organic material and produce these saprophytic products which are harmful to the disease producing bacteria.

Q. Is there any way of removing these saprophytic products other than by boiling?

10380 A. There is not so far as I know.

Q. Is it eliminated by the running of the stream?

A. I do not think that it is eliminated by the running of the stream, it is simply diluted.

Q. By the addition of other waters?

A. Yes sir.

Q. And if the other waters are infected by the same product why of course there would be no betterment of conditions?

A. If the other streams are polluted with the same material the same saprophytic products are produced which are again harmful to disease producing bacteria. The reason of the saprophytes multiplying more in water than the disease producing bacteria is because the temperature of the water is more favorable to the multiplication of saprophytes than it is to the multiplication of parasites, therefore pathogenic or disease producing bacteria can not multiply in lake or river water. They are not destroyed, if the lake or river water was pure and free of all polluting organic material and therefore free or practically free of saprophytic life. As soon, however, as there is any pollution whatever with organic material you have an increase of saprophytes and an increase of saprophytic products and then the few disease producing bacteria that are
10381 present, and that were unable to multiply, are now destroyed by the saprophytic products. I originally thought that this effect of the disappearance of the typhoid bacteria was really due more to the over growth of saprophytes, making the

conditions of life for typhoid bacilli unfavorable, than to the saprophytic products which are diffused through the water, but I have convinced myself now by these filtering experiments, that there is in the river water sufficient of these saprophytic products present to destroy disease producing bacteria.

Q. Now, Professor, if the boiling of the water destroys the saprophytic products, why is it that a germ will not live indefinitely when placed in water having been boiled?

A. Because some of the saprophytic products are not destroyed by boiling. What I call saprophytic products are substances of a very complicated nature of which we know very little in chemistry or bacteriology. We do not know today even the chemical composition of the diphtheria toxin or antitoxin, and similar products. We know but very little of the chemistry of these products. They are no doubt very complex and very numerous, innumerable. Some are more affected 10382 by heat, some are less. But we can not conclude that all those which are poisonous are destroyed by heat because we know that that is not true. Some of the poisonous products are not destroyed by heat although most of them are.

Q. Now, in making your investigation as to the longevity of the typhoid germ in this boiled water you found sometimes that they lived three days and from that to fifteen days?

A. In boiled water in Lake Michigan they lived as long as 15 to 18 days.

Q. Now, did you make some experiments in which you failed to find any prior to the expiration of 15 days?

A. In boiled lake water we have always found them for 15 days and even more. That is we found them for 15 days and then did not always examine any further. Now, such is not the case in the river. In the river, while they also lived longer in boiled than in filtered water, they disappear sooner so that there must be present in the river water certain substances that are injurious to the typhoid bacillus which are not destroyed by boiling, although river water is not as deadly to the typhoid bacillus when boiled, as when it is only filtered.

Q. Do bacteria living but not multiplying in water produce these saprophytic products?

10383 A. They do not. Saprophytes are non-disease producing bacteria, they do not produce infection, whereas disease producing bacteria are parasites and produce infections. The saprophyte is a germ that lives on dead organic matter. Disease producing germs are germs that live on living organic matter.

Q. Do bacteria, living but not multiplying in water, produce any product?

A. I should judge not. The products of the germ are due to the multiplication of the germ. When the germ finds food and multiplies in a favorable temperature then it also produces excretion products. If, therefore, no multiplication takes place, the food conditions are unfavorable and the temperature conditions are unfavorable, and if it does not multiply it will not produce these excretion products. To illustrate: If you inoculate a nutrient bouillon tube with the diphtheria bacillus and you place that tube in the ice box where the bacillus can not multiply, it will not produce diphtheria toxin in the tube. It will only produce diphtheria toxin if you place it at blood temperature where the bacillus multiplies and uses up organic material in the bouillon and when it multiplies it produces excretion
10384 products which are so poisonous that 1-100 of a cc. can kill an average size guinea pig in 15 minutes. Now, if you prevent that multiplication by lack of food or low temperatures there will be no poinsons in the tube, so I should answer your question by saying that they will not produce such poisonous products when they do not multiply.

Q. You say that the only object of using these parchment and celloidin sacs was to allow osmosis so that excretions would be removed?

A. Yes sir, the excretions of the saprophytes in the sac could be removed. Objections were made to some of my previous experiments in which I had filled liter flasks of the water of the lake or the water of the Illinois River or the Mississippi River or the Missouri River and then infected them with typhoid bacilli and then determined how long typhoid bacilli would live in those bottles. It was stated that in my bottles the saprophytes could multiply more rapidly than the typhoid bacilli and therefore the products of the former would remain in my bottles and kill the typhoid bacilli. I have admitted that to be possible, and that is one of the reasons why we made these experiments so as to exclude and overcome the objection raised by Mr. Jeffries.

10385 Q. Would the toxin products or other bacteria excretions pass through these sacs?

A. Just as well. The toxic products in the sac could pass out and the toxic and other excretion products of the bacteria outside of the sac in the river could pass in, so that there ought to be a fairly free interchange of different bacterial products through the wall of the sac in and out. By osmosis the conditions would eventually become the same in regard to the quality of the bacterial products present outside as well as inside of the sac.

Q. Would the dissolved oxygen of the river or other water used pass through the sac?

A. That would.

Q. Now, in reference to the length of life or longevity of these typhoid germs, Professor Jordan, I think, multiplied the length of life by two in order to be certain and I think probably by three. Now, Professor, as a precautionary measure what do you say about that?

A. I have here given purely the results of my experiments. In those experiments we were careful to take up every colony shown on some of those plates so that I know typhoid bacilli were not there any more. Further, in some of the waters
10386 in which the typhoid bacillus had disappeared after the third and fourth day we would employ the method which I described yesterday of agglutinating and precipitating typhoid bacilli from a large quantity of water—we usually used 50 cc. of water. We would add to that the immune serum, clumping the typhoid bacilli that were present in the water, and then we would take the sediment from this quantity due to the clumping of any typhoid bacilli, if there were any, and plate those out. Now, it has been shown by that method which is one of the most recent ones, that you can detect the typhoid bacilli if there was one part of typhoid bacilli to many thousand million parts of water. It was this method which I quoted yesterday as having experimented with, to first see if I could find them that way. By this method I was unable to find them on the fourth day. I think I may say that the bacilli were not present in that water. Now,

I see no reason why I should extend the time and say that they may be present so much longer or that certain very resistant forms of bacteria might be there so much longer. I simply want to apply the results of the experiment and say that they could be found so long at the longest. Now, sometimes I have found them to live a shorter time for one day. I have stated the longest time for which we were able to find them with the most exhaustive work in detecting them. If we were to
10387 judge that certain resistant forms could live very much
longer then the value of these experiments would be doubtful. If this was simply a matter of speculation as to whether they might not live twice as long or three times as long as the experiment, it might be argued also that they could live ten times as long. I think I want to strictly confine myself to the actual findings that I have given here and say that they live that long and that I know by the experiment on the filtered water of the river that they die in two days or less and in non-filtered river water in three days or less.

Q. Professor, would not the length of the life of these germs depend sometimes upon their virulence and the strength of the particular germ?

A. Some germs are slightly more resistant than others, but we had a very motile and very resistant germ.

Q. To which one do you refer now, strain X or B?

A. The strain "O," the Parke Davis strain, which was used in the immunization of a horse for the purposes of prospective serum treatment of typhoid fever patients.

Q. Was not that a somewhat unreasonable thing, Professor?

A. What?

Q. The treatment of a horse?

10388 A. It was not unusual. Parke Davis & Co. are trying
to produce immune serums for the treatment of infectious diseases, and in doing so they must experiment with many different cultures to obtain the highest immunizing value of the serum in the horse, and they would naturally confine their experiments to one germ that had proven the most efficient, the most virulent germ. That is the one they must use. For their diphtheria anti-toxin, they must immunize horses. They have

to raise the virulence and vitality of the diphtheria bacillus to such a point that the poisons produced by this germ will kill an animal in the dose of .01 cc. The virulence and vitality of the germ is usually increased by passing it through a series of animals, and a horse is then immunized by repeated injections of these filtered poisons. Afterwards the blood serum of the immunized horse is used as anti-toxin for the treatment of patients. In the case of their typhoid bacillus, the high agglutination power of the horse's serum speaks best for the activity and virulence of the typhoid bacillus used in our experiments.

Q. This was the first horse that was ever immunized with typhoid germs within your knowledge, was it not?

A. I do not know how many horses they are immunizing, but this is not the first one.

Q. Do you know of others?

A. Dr. Larned tells me they had numerous horses that are injected continually with all kinds of disease producing 10389 bacteria or toxins.

Q. Now, Doctor, this strain taken from the horse is manifestly different from the strain that would be taken from the typhoid fever patient?

A. All typhoid bacilli come from human cases, not from the horse. We have also used one strain that came directly from the blood of the typhoid fever patient, bacillus X received from Prof. Jordan. Of the horse we used only its serum. The bacillus was used for injecting the horse and producing an agglutinating serum.

Q. Now, there was a difference in those strains, was there not?

A. There was no difference in the results of the experiments between the two germs.

Q. Then in your opinion there was no difference between these two strains?

A. There was no difference in those two strains as far as I could see except in the Parke Davis strain we had, besides the bacillus, the serum of a horse which had been highly immunized with it. That made it so much easier for us to discover the typhoid bacillus in the plates when it was present.

Q. Doctor, did those sacs that you placed in the water become coated with any sort of material?

A. After ten days they had become quite coated and we 10390 found in the first experiment that the sac lasted about two weeks.

Q. After how many days did you say?

A. Ten days.

Q. So that the first you noticed of this coat being formed was after the expiration of about ten days?

A. The coat began to form already after a few days, but it was not very noticeable until five or six days and by ten days the coat was quite thick.

Q. What effect did this have upon the osmotic products of the sac?

A. The osmosis must have been slightly less than it was when the sac was fresh.

Q. Do you not think this coating began to form about the third day?

A. The coating was not noticeable until the third, or fourth or fifth day. It was insignificant the first days and was certainly such as not to prevent osmosis for a week, in the least. This slimy coat does not prevent osmosis. It may make it slightly slower but it can not prevent it. The only objection to the slimy coat was that after two weeks it would produce leaks in the sac and thus spoil the whole sac by that time.

Q. Did you find this same coating in the lake water experiments?

10391 A. In the lake water experiments it was much less although some coat formed also.

Q. Did you find it where you had boiled the water?

A. In boiled water, how do you mean?

Q. Well, after you had boiled this water and put it in these sacs did you find this coating on the sac?

A. We only kept that in bottles for a few days. In the lake water in ten days there is no appreciable coat on parchment sacs. If you keep it for two weeks or twenty days in the river the sac rots. If in the lake water it probably takes three weeks or maybe four weeks for the sac to become deficient by rotting.

Q. Now, you used the agar plates, I believe?

A. Entirely, from the first plating out.

Q. Now, did they show these colonies as clearly as the Hiss medium?

A. That is all a matter of experience. I have been able to detect large numbers of typhoid colonies on the agar plates in the heavily seeded sacs after three days. After three days the whole character of the plate was usually changed, sometimes after two days, and then if we did not find any more typhoid like colonies we would take off every colony on the plates and transfer it to Hiss medium. Every one of the plates from the river where we used 0.001 cc. of water, and in the case of
10392 lake water the plate to which 1-2 cc of water was used,
we found we could get plates with a few hundred colonies only. We would thus inoculate from one plate some 300 colonies, that is, all the colonies on the plate, into the Hiss media. None of these proved to be typhoid bacilli so that I could quite safely say that in that whole plate there was not one typhoid bacillus and this water had been stirred and mixed.

Q. Professor, I think you testified that in one experiment that a typhoid germ lived in lake water eight days and in another experiment a germ lived four days. Now, might not still another germ live for a longer period of time?

A. That depended upon the seeding. If the seeding was very heavy we would find them a little bit longer. If the seeding was light they would disappear in a shorter time. The same holds true also in the river when I gave three days as the longest time we found them in the river. I meant there the heaviest seeding that we used, that is over a million typhoid bacilli to every cc. of water in the sac.

Q. Does not the longevity of the germ depend upon its
10393 strength or virulence.

A. That is one factor.

Q. Then the life or the length of the life of the germ depends upon the hardness of the germ itself?

A. That is only one factor. The more important factors are the surrounding, temperature and food conditions and competitive other saprophytic bacteria present.

Q. What time of the year was it that you made these tests, Professor?

A. October, November, December and January.

Q. Suppose the tests had been made during the hot summer months?

A. I am quite certain that if these tests had been made in the hot summer months that we would have found them to die sooner yet than what we state here, because the saprophytic multiplication in the summer must be a great deal more pronounced than it is during the time of our experiment.

Q. But you made no experiments during the summer months?

A. We did not.

Q. What is osmosis?

A. By osmosis we mean the interchanging of material between fluids on two sides of an animal membrane, until
10394 the contents of crystalloids in the fluid on one side of the
animal membrane is the same as the contents of crystalloids on the other side of the animal membrane, and the equalization of the specific gravity of the fluids on both sides of the animal membrane. Now, to illustrate that still further: If on one side of the animal membrane we have a salt solution of a specific gravity we will say of 1040 and on the other side of the animal membrane we have a salt solution of a specific gravity of 1002, then osmotic pressure causes a passage of the solids through this membrane from the one of higher specific gravity to the lower until the two are equal. That is osmosis. In other words if there is an animal membrane between two fluids of different specific gravities, osmotic pressure is brought about in the direction from the higher to the lower, until the specific gravity of both fluids on both sides of the membrane is the same, and therefore if in our sacs the specific gravity produced by the multiplying of the saprophytes, resulting in excretions, which in my bottles might have destroyed the typhoid bacilli, but which here produce a greater specific gravity than existing in the water outside of the sac, then these increased saprophytic products would pass out through the parchment membrane sac
which acts just the same as an animal membrane, until
10395 the specific gravity outside of the sac were the same as
the specific gravity inside the sac and vice versa if the specific gravity of the contents of the sac was lower than that existing in the outside water, then the crystalizable substances, the so called crystalloids, of which nature are the saprophytic

or disease producing bacterial products, would pass into the sac until the specific gravity of the fluids on both sides were the same. Whenever the specific gravity of fluids separated by such membranes varies, osomotic pressure is set up from the fluid of the higher specific gravity towards that of the lower until the two are equalized.

F. ROBERT ZEIT.

ADJOURNED UNTIL 2:00 P. M., SAME DAY.

10396 2:00 p. m., Tuesday, February 16, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. VICTOR H. BASSETT,

a witness called on behalf of the defendants, first having been duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Mr. Todd.

Q. What is your name?

A. Victor H. Bassett.

Q. Where were you graduated?

A. I graduated from Knox in 1896, from Knox College at Galesburg, Illinois.

Q. After graduation what did you do?

A. I took up a scientific work in the University of Wisconsin, beginning in 1896.

Q. How long were you there?

10397 A. I was there until the fall of 1899.

Q. Who were you under in the University of Wisconsin?

A. I went there in the spring of 1896. For the first two years I was assistant in chemistry under Dr. Daniels, and the following year I became assistant to Dr. Russell and remained with him one year.

Q. After leaving the University of Wisconsin where did you go?

A. I went to Johns Hopkins Medical School.

Q. At Baltimore?

A. Yes, sir.

Q. How long were you there?

A. Four years.

Q. While there what did you do?

A. I took the medical course and acted as an asistant at the same time.

Q. Assistant under whom?

A. I was assistant under Dr. Harris, in Dr. Welch's Pathological Laboratory, specifically in the place of what they call a student assistant.

Q. And did you do anything else in Baltimore except that?

A. During the last two years that I was there, during the summer season, I acted as bacteriologist to the Thomas Wilson Sanitarium where children who have summer diarrhoea are cared for.

10398 Q. After leaving there, what did you do?

A. Following my graduation in June I spent another summer at the sanitarium and on the first of October became an assistant to Professor Zeit of the Northwestern.

Q. Northwestern, what?

A. In the Medical College of the Northwestern University.

Q. Did you assist Professor Zeit in the experiment which he made upon the waters of the Chicago river and Lake Michigan, testing the longevity of the typhoid bacillus?

A. Yes, I did.

Q. What part of the experiment did you conduct?

A. I did what might be called the more active part of preparation and gathering of samples and then together we sought for the organism in the water samples gathered.

Q. Will you explain what you mean by preparation?

A. Well, it was necessary to prepare media, prepare sterile glass ware, to have cultures of the organism to be studied, to seed the waters studied, and place the preparations in the river and in the lake water, and collect the samples.

Q. What means were employed to make this experiment?

A. It was designed by means of placing suspensions of 10399 the typhoid bacillus in river water and in lake water, closed in parchment sacs and in celloidin sacs, suspended in river and lake water respectively, to subject them to the conditions which existed in the river and lake.

Q. At what points were those experiments conducted?

A. The examinations of the river water. The samples of the river water were taken from the Chicago river at the Ashland Avenue bridge. The lake water specimens were specimens of tap water taken in Dr. Zeit's laboratory, in the Post Graduate Hospital.

Q. How many sacs of parchment and how many sacs of celloidin were used in this experiment at Ashland Avenue?

A. I used five parchment sacs for the typhoid organism and one for the dysentry organism. I used one set of celloidin sacs in the river and one set of celloidin sacs for typhoid and one set for dysentery in lake water.

Q. What do you mean by one set?

A. Well, the celloidin sacs were made quite small. It is not easy to make them so large as the parchment sacs, so
10400 that in place of conducting the experiment by taking samples from the sacs, I prepared a number of sacs and subjected them to the same conditions and took one daily as a sample. In the lake water it was possible to take a small portion of the water from one of the celloidin sacs, on account of convenience of working in the laboratory.

Q. How were these sacs tested after being prepared?

A. They were tested first for their integrity, that is for the presence of holes. I did this by blowing them up, that is testing them as one does a bicycle tire by putting air pressure into them and placing them under water, I found that if there was only a minute hole that the escape of air would show its presence. I further tested them by determining whether substances which could not pass through parchment membranes by osmosis would be found in water outside the sac when the sac was suspended and filled with such substances. For this I used egg albumen in water solution. I filled the sac and left it suspended in water 24 hours to 48 hours and then tested the water outside the sac for albumen. In some cases I found albumen, in which case I found holes in the sac and discarded them, and when I did not find albumen and when they did not show
10401 the presence of holes by this air pressure test, I considered that they were intact. The celloidin sacs I tested in the same way. I also tested their osmotic property by placing in them solutions of salts which I might say would pass through permeable membranes, and I found these were

permeable to salts such as sulphate of magnesia. That shows that such substances can pass from them through them, even when there are no holes, and that osmosis could occur readily.

Q. After the sacs were prepared and taken to Ashland Avenue bridge, who placed them in the water?

A. I did.

Q. Just describe the method that you pursued in placing them in the water?

A. I had prepared the box about 3 feet long at first, and I lengthened it a little. The lower 2 feet of the box on each side was covered with a coarse netting, with a mesh about 3-8 of an inch, I judge. Inside the box was a shelf on which there was a series of clamps in which the glass tube in the top part of the parchment sacs could be clamped. The upper part of the box was outside the water, and the lower part underneath the water about 2 or 3 feet.. This box was fastened to the pier of
10402 the Ashland Avenue bridge, about 30 feet out in the river, where the water was said to be about 20 feet deep.
The celloidin sacs I placed in a box which I floated in the river, attaching them to a shelf. I tied them to little pegs.

Q. How were these sacs infected?

A. I prepared 24 hour cultures on agar of the typhoid organisms to be tested and then made suspensions in the first place in the water itself, infecting directly (or suspending the typhoid organisms in salt solution, which I then added to the water). In the earlier experiments I added to the water direct a certain amount of the agar culture of the typhoid organisms, that is of the growth upon the agar. The later samples I infected by preparing suspensions in 100 cc. of sterile salt solutions, and added varying portions of this to the sacs containing the water.

Q. Confining yourself first to the parchment sacs, how many typhoid bacilli were placed in these sacs?

A. In the first series of three sacs I infected heavily. Two of them I infected with about one and one-half million organisms per cc. The third sac I infected exceeding two million
10403 per cc. The water at this time that I used contained about 200,000 organisms per cc.

Q. In doing this work you were acting under instructions from Professor Zeit?

A. Yes, sir, we decided upon the plan of work.

Q. Now, after these sacs were placed in the water who collected the samples?

A. I collected the samples myself.

Q. What method did you employ in the collection of these samples?

A. In making the earlier collections I unlocked the box in which they were placed and carefully took the sacs out, shaking them up somewhat, by tipping them back and forth and then by means of the sterile pipette I withdrew about an ounce of water and let that run in the sterile bottle and carried it to the laboratory.

Q. Before taking the samples out of the sac what was done to the sac, if anything?

A. Well, I first observed the sac to see whether it was intact and then took the end of it and tipped it back and forth, shaking the water to get an even seeding, and usually also
10404 assisted the shaking of the water by drawing up some
of the water in the sterile pipette and letting it flow back.

Q. How were the celloidin sacs seeded and placed in the water?

A. It was necessary to seed those in a somewhat different way. I brought the water to the laboratory and then infected it in a similar way to that in which I infected the water from the parchment sacs and having made plates to determine the seeding then by means of sterile pipettes filled these small sacs from this stock solution of infected water.

Q. Then what did you do with the celloidin sacs?

A. The sacs were then taken at once and placed in the river?

Q. Who took them out of the river to the laboratory?

A. I took them.

Q. How many experiments did you carry on there?

A. I did five experiments in the river with parchment sacs.

Q. On the typhoid?

A. On the typhoid, one on the dysentery organism. I did one experiment, that is, I tested one set of celloidin sacs, infected with the typhoid organism, and one series infected with the dysentery organism.

Q. That made eight experiments?

A. In the river, yes.

10405 Q. Now, how many celloidin sacs in all were placed in the river?

A. I put from 6 to 10, a sufficient number, so that I could conduct the experiment about 10 days. When I used six sacs as I did in one case, I had to take the samples every other day, in the latter part of the experiment.

Q. How were the celloidin samples taken?

A. I brought the sac entire to the laboratory and then removed the water by means of a sterile pipette. I did that in the case of the river water. In the case of the tap water I at times left the sac remain in the water for several days. That is, I often did not remove the sac entirely, but took out a small portion as a sample and replaced the sac in the tap water, taking a second sample the following day.

Q. The typhoid bacilli that were placed in those sacs were typhoid bacilli given you by Professor Zeit?

A. I secured the first culture which we used from Professor Jordan. It was sent by him.

Q. That was the sample that Professor Jordan sent to Professor Zeit, known as strain X?

A. Yes, sir. The second was a culture sent to Professor Zeit from Parke, Davis & Company, taken from a case of 10406 typhoid fever, and known as their culture "O." In addition to that I used in some of my control experiments a third culture which we had in the laboratory and which I isolated from a case of typhoid fever in Johns Hopkins Hospital.

Q. After the samples were taken out of the water and delivered to the laboratory they were tested for the presence or absence of typhoid bacilli?

A. Yes, sir.

Q. When were these sacs first placed into the Chicago river at Ashland Avenue?

A. The first series was placed in the latter part of October, from the middle to the latter part, I should judge about the 20th. I placed a sac about the first of January. That was a celloidin sac, and also another parchment sac about the first of December.

Q. When were they taken out?

A. Well, I ran the experiments about ten days. Some of the sacs I left in, and did not take out at all, that is, I did not remove them from the water.

Q. When was the last sample of water taken from Ashland Avenue?

A. I am still taking it from the celloidin sac series.

What?

10407 A. I am still taking from one series. The last one I took complete was about the middle of January.

Q. That is what I mean, this experiment that Professor Zeit testified about?

A. Yes, sir.

Q. Now, after the samples were taken to the laboratory, analytical determinations made, everything was reported to Professor Zeit as to the results that were made, were they not?

A. Yes, sir; I made cultures and then we worked upon those cultures together, and I reported to him fully in regard to the work.

Q. The dysentry bacillus that was made at this time, was made by yourself?

A. Yes, sir.

Q. Professor Zeit did not participate in that?

A. No, sir.

Q. Will you detail the method that you used in the dysentry bacillus, and how the experiment was made, and when it was made, in full?

A. I tested the longevity of the dysentry bacillus in the river water, beginning the first of December, placing it in a parchment sac. I made a second experiment in the river 10408 water about the first of January, placing them in celloidin sacs. I made a third experiment placing the dysentry organism in celloidin sacs, in tap water, at about the same time. The sacs were prepared and seeded in a method similar to that which I have already described. I used cultures of bacillus dysenterial Shiga. I used two strains, one a subculture of Shiga's original culture, the alkaline form of the dysentry organism, and the second a culture of the acid form of the dysentery organism, isolated from a case of summer diarrhoea at Mt. Wilson in 1903, by myself.

Q. Where did you get the Shiga bacillus that you employed in this experiment?

A. This was a culture which was a subculture of one of the stock cultures at the John Hopkins Pathological Laboratory.

Q. Now, proceed, Doctor, with the experiment, just as you made it?

A. In the first series in December I seeded the river water with several hundred thousand of dysentery organism per cc. The water contained about 8,000 or 10,000 water and sewage organisms at that time. I took samples of the water daily and made plate cultures in agar agar, making a large number
10409 of plates, usually as many as 15 or 20. These plates were
set in the thermostat and at the end of 24 hours the colonies which appeared were marked. I then placed them in the laboratory a second 24 hours, and at the end of that time looked for colonies which had appeared on the second day. This process is one which was developed by Dr. Flexner and his pupils and has been specially valuable for the isolation of the dysentery organism. It depends upon the principle that the dysentery is slow in growing in mixed cultures and colonies usually do not appear in the first day. One is able then to pick out, with certainty, dysentery colonies from the colonies appearing later. I made subcultures from these which appeared in the second 24 hours upon special media making them usually on a slant litmus glucose agar on which dysentery organisms grow in a characteristic manner. I was able to throw out all gas formers, all alkali forms and all other organisms which grew in an unsatisfactory manner unlike the dysentery organism and proceeded then to cultivate the organisms which resembled dysentery and established their identity by the agglutination test with ante-dysenteric serum. In the experiment in the river I was able to find the organism for three days; and even with heavy seeding I found them only three days, and then up to
10410 about the tenth day I was unable to find any.

I made experiments in a similar way, about the first of December, using celloidin sacs, seeding them in a similar way, using, however, a rather smaller number of organisms, about 10,000 per cc. I was able to find the dysentery organism on the first and second days, in lake water, and on the first day only in river water.

Q. Did that complete your experiments on the Shiga?

A. Yes, sir, in connection with these waters.

Q. How long did you find that the Shiga bacillus lived in the waters of the Chicago river?

A. With a heavy seeding, that is, several thousand organisms per cc. I succeeded in finding it on the third day when it was mixed with water which contained a few thousand water bacteria per cc. When it was mixed in the proportion of 10,000 per cc. with water which contained several hundred thousand water and sewage organisms I found it only on the first day.

Q. What means did you employ for determining the presence of the Shiga bacillus?

10411 A. I used the plate method, and the method of marking the colonies and identifying by culture media and by agglutination of the anti-dysenteric serum as described.

CROSS-EXAMINATION, by Mr. Corum.

Q. Will you give the number of days which the typhoid bacillus lived in each of your experiments that were made at Ashland Avenue?

A. Of the first series of experiments made in October I started in with 5 sacs, one on the first day was punctured in taking it out, and I was obliged to discontinue that. One was a control in which I put salt solution infected with the typhoid organism. That became infected on the second day, and so was discontinued as a control. I found the typhoid organisms in there on the third day and not later. And of the other three sacs—these are parchment sacs—one which was infected with over two million organisms per cc. to about 200,000 water organisms, in that I found the organisms on the third day and not later, and I made a single culture as late as the 15th day.

10412 In the other two which were seeded with about one and one-half million organisms per cc., I found the typhoid organisms on the second day and not later than up to the tenth day.

That included all the tests made in October, making five experiments, omitting the one which I was obliged to discontinue.

I made a second experiment in a parchment sac, beginning the first of December. This was inoculated with about 20,000 organisms per cc. to about 8,000 water organisms, and in that I found the organisms on the first, second and third days, and later I did not find the typhoid bacillus, continuing experiments until the ninth day. In this on the fourth and on the ninth day I made a special examination by means of taking off all the colonies on a plate which was seeded with three hundred or four hundred organisms, and also by taking about 50 cc. of water, attempting to precipitate the typhoid organisms, if present, with serum and plating out the precipitate. These were negative on the fifth and ninth days. This method is the method that Schepilewsky described in the Centralblatt fur Bakteriologie, 33rd Volume.

10413 The next series was a series begun on the 30th of December, a series of celloidin sacs, which I inoculated with about 11,000 typhoid organisms per cc. to 640,000 water organisms. In this I found the typhoid organism on the first day, not on the second, fifth or ninth days, using the special methods already described.

I find that I was mistaken in that I had done one celloidin experiment in the river only and two experiments in the tap water, making seven in the river.

Q. Now, in your testimony you have been referring to the experiments in the river?

A. Yes, sir.

Q. In this Chicago river?

A. Yes, sir.

Q. Now, I wish you would refer to your experiments in the lake?

A. I did two experiments in October, suspending the sacs as described in Professor Zeit's laboratory, in one of which I infected with about one and one-half million typhoid organisms per cc. I examined those daily for fifteen days and found the organism on the fifth day. The second one I infected in a similar way and found the organism on the seventh day.

10414 In November, beginning the 18th of November, I did an experiment with the parchment sac, which I infected similar to those described and in that I found the organism on the eighth day and not later, for six days later. In this I determined by the methods described, the absence of the organism. I made a second experiment in which I placed a parchment sac in air and I found the organism on the 5th day and not later to the 12th.

I did another experiment in which I used celloidin sacs, infecting them in a similar manner, and I found the organism on the 7th day and not later to the 14th day.

Q. That was lake water, too?

A. Yes, sir. I did a control experiment in which I used boiled lake water, and I found the organism on the 15th day.

Q. When you speak of organism you mean what?

A. The typhoid organism.

Q. That is all of the typhoid experiments that you performed?

10415 A. Yes, sir, with the exception of some controls.

Signature waived. F. S. B., Com'r.

Adjourned until 10:00 a. m., Wednesday, February 17, 1904.

10416 10:00 A. M., Wednesday, February 17, 1904. Parties met pursuant to adjournment. Present the Commissioner and same counsel representing the respective parties.

There being no witnesses present, an adjournment was taken until 10:00 A. M., Thursday, February 18, 1904.

10417 10:00 A. M., Thursday, February 18, 1904. Met pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

PROF. H. L. RUSSELL

a witness called on behalf of defendants, being first duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION

By Mr. Todd.

Q. What is your name?

A. H. L. Russell.

Q. Where do you reside?

A. Madison, Wisconsin.

Q. What is your business?

A. Teacher.

Q. In what capacity?

A. I am in charge of the department of Bacteriology in the University of Wisconsin.

10418 Q. What institution were you graduated from Professor?

A. I received my bachelor's degree from the University of Wisconsin in 1888; remained there as Fellow in Bacteriology until 1890, and then went to Europe and studied in Koch's Institute in the University of Berlin, in the Zoological station at Naples, and in the Pasteur Institute at Paris. I returned to America in 1891 and took my Ph. D. degree at Johns Hopkins University.

Q. When did you assume the professorship in the University of Wisconsin at Madison?

A. 1893.

Q. What experience have you had in sanitary work?

A. I have been connected, since 1894 with the Wisconsin State Board of Health as Bacteriologist, and in that capacity as well as in a private capacity I have had to do with the analysis of waters from a bacterial point of view, for sanitary purposes.

Q. What water courses have you investigated?

A. We have had the examination of all the waters which were submitted for public analysis in the State since that time and have been engaged especially in an examination of
10419 the water supplies of the cities of Superior, Ashland, Marinette, Menominee, Michigan, Merrill, Steven's Point, Warsau, Eauclaire, Portage, Green Bay, Beloit, Baraboo, and Dubuque, Iowa, besides a number of smaller places.

Q. Have you made a special study of sanitary problems?

A. In connection with this work I have carried out investigations on the sanitary nature of waters.

Q. Have you studied any typhoid fever epidemics?

A. Yes sir. The very severe outbreak of typhoid fever in Baraboo, in the year 1901, and I had the examination of the waters at the time of the typhoid outbreak in Ashland, and just subsequent to the typhoid outbreak in Superior, Wisconsin. Also in Menominee, Michigan, and Marinette, Wisconsin. Those are the main outbreaks.

Q. Are you acquainted with the literature bearing upon typhoid fever epidemics?

A. Yes sir.

Q. Are you acquainted with any epidemics other than typhoid fever?

A. Relating to water born diseases?

10420 Q. Yes?

A. In connection with water born diseases I have studied the literature with reference to outbreaks caused by Asiatic cholera, organisms producing gastro intestinal diseases, dysentery, and also anthrax.

Q. Have you made a special study of water analysis?

A. In connection with the work previously mentioned it has been necessary for me to make a bacterial analysis of water in large numbers. I have not studied from a laboratory point of view the chemical side of it so much.

Q. What branch of sanitary science have you given special attention to?

A. Bacteriology.

Q. Have you had any experience in the interpretation of the chemical analyses of water?

A. In the course of our sanitary work in the State the waters are received by me. Samples of the same are taken out for bacteriological analyses and the balance of the samples turned over to the State Chemist. His report comes to me merely as a chemical report, without any interpretation, and it has been necessary for me to combine the results of the bacteriological and chemical examination, and give a proper

10421 interpretation of the coordinated methods of analysis.

Mr. Todd: Mr. Commissioner, have you compared all the tables and charts introduced in evidence with all the tables and charts contained in the book known as reports of Streams Examinations published by the Sanitary District of Chicago? I ask this question for the purpose of simplifying my examinations as I will refer to Streams Examinations instead of to the individual tables that have been introduced in evidence.

The Commissioner: I have made this comparison and have found that all the tables and plates printed in the publication referred to have been copied into the testimony in this case by the witnesses who have hitherto testified.

Counsel for complainant makes no objection to this interrogatory or answer.

Q. Have you examined and studied the bacterial and chemical analysis of the waters of Lake Michigan, the Drainage Canal, the Desplaines River, the Illinois River, the Mississippi River and the Missouri River as made by Professors Jordan, Gehrmann, Palmer and Burrill, the same being published in what is known as "Reports of Streams Examinations," published by the Sanitary District of Chicago?

10422 A. I have.

Q. What opportunities have you had for becoming acquainted with the water course from Chicago to St. Louis?

A. In September, 1903, I made a trip, in conjunction with a number of other individuals, from Chicago to St. Louis, by way of the drainage canal, Desplaines River, Illinois River, Mississippi River and had given me special opportunities for the physical examination of those streams.

Q. How was this trip made?

A. This trip was made by boat from Chicago to Lockport; we then went by rail from Lockport to Joliet, and from Joliet to Peoria on the Rock Island, and then took the Fish Commissioner's Steamer, Illinois, at Peru and made the continuous passage from there to St. Louis, stopping en route during the night so as to give an opportunity for the physical examination of the stream throughout its entire course by day light.

Q. Did you go up the Mississippi?

A. We went up the Mississippi at its junction with the Illinois to Grafton, for the distance of a few miles, so as to observe the physical conditions of this stream before and at its confluence with the Illinois.

10423 Q. Have you made a special study of bacteriology?

A. I have.

Q. What are bacteria?

A. Bacteria are one celled plant structures of the very lowest order of existence. Their methods of reproduction and nutrition ally them with the plants, not possessing green coloring matter, rather than with the animal forms of life.

Q. How are they classified and distinguished?

A. The bacteria are classified primarily on the basis of the form which the cell assumes, there being three fundamental type forms, known respectively as coccus, bacillus and spirillum. The extreme simplicity of the bacteria renders it necessary to bring into the classification of this group of plants a variety of

physiological data, which are not used in the classification of
the more highly organized forms of life. These physiological
data refer to the growth of the organisms on various kinds of
culture media, the reactions which are produced in these media
as a result of this growth, the appearance of the organisms
as grown in masses technically known as colonies and
their relations to other forms of life when artifically in-
10424 troduced into them, such as is the case with the patho-
genic or disease producing bacteria.

Q. How are they distributed?

A. The bacteria are almost universally distributed in nature, being found over the surface of the earth in varying numbers.

Q. What are the characteristics of bacteria peculiar to water?

A. The water bacteria, those that are normally native to this habitat, belong to the group of organisms which are technically known as saprophytes, that is, organisms living upon dead organic matter in contradistinction to the parasitic forms which live upon live organic matter. The water bacteria possess also in addition to this characteristic of growth upon dead material, the ability to thrive in solutions which contain a minimum amount of organic nourishment. So that under natural conditions in waters which are relatively free from organic matter many of these organisms possess the power of multiplication in a very great degree.

Q. Please distinguish between the so called saprophytic and parasitic bacteria?

A. The saprophytic bacteria live upon dead matter. The
parasitic bacteria grow in and on living material. The
10425 parasitic bacteria are divided into two groups one of
which is called the obligatory parasites, when the organ-
ism is unable to grow on any material which is not alive The facultative group possess the power of growing on both live and dead material. This production of pathogenesis is subject to material alterations in intensity, owing to the environmental conditions under which the organism is placed, and it is therefore possible to deprive a normal pathogenic organism of its power of producing a diseased condition in the number of susceptible hosts.

Q. Distinguish between the pathogenic and non-pathogenic bacteria?

A. The distinction of pathogenic and non-pathogenic bacteria is a different classification from the parasitic and saprophytic. The pathogenic bacteria are parasitic, although there are organisms that are capable of producing a pathogenic effect that are not strictly parasites. The non-pathogenic classification is merely a negative one, including all organisms which can not come under the pathogenic or disease producing class.

Q. What are the known pathogenic bacteria to man?

A. The most commonly recognized pathogenic organisms
10426 for man are those which cause the diseases of typhoid
fever, diphtheria, tetanus or lock jaw, Asiatic cholera, Bubonic Plague, dysentery, cerebro spinal meningitis and anthrax.

Q. What pathogenic bacteria are water borne when taken into the human body by means of drinking water?

A. The most common organisms of this class are the organisms producing the diseases of typhoid fever, cholera, dysentery, anthrax, under certain conditions also organisms capable of producing certain gastro-intestinal disturbances. These are the ones most likely to be disseminated through the medium of water.

Q. What is the bacillus prodigiosus?

A. The bacillus prodigiosus is a well recognized harmless saprophyte that is one of the best known of any which are studied in the bacteriological laboratories. The organism is especially easy to recognize on account of its ability to form a, red pigment on certain food media which with other means leads to recognition.

Q. Will you give its characteristics and life history?

A. The characteristics of bacillus prodigiosus are that it
10427 is a short plump organism. On culture material it is capable of liquefying gelatine, producing a funnel shaped liquefication in the test tube, in which there is a slight accumulation of red pigment. On the cut surface of a potato the organism grows luxuriantly forming a thick mass of bacterial growth which possesses a blood red color, changing to a metallic luster with increasing age. These cultures frequently possess a herring brine odor, which is a characteristic of the organism.

Q. Is it found in river water?

A. Bacillus prodigious is occasionally found in river water, as well as other locations of the outside environment.

Q. Have you found bacillus prodigiosus in the water of the western country?

A. Yes sir, in several instances I have found the organism known as bacillus prodigiosus under external conditions. Several of these cases have been in samples of milk which were examined, but in other cases I have found it in water supplies which were reasonably certain to be entirely free from any polluted material.

Q. Are you acquainted with the experiment made with the bacillus prodigiosus, by Dr. Ravold?

10428 A. Yes, I am conversant with the data which has been presented in connection with the case.

Q. Assume that 107 barrels of 40 gallons each of culture of bacillus prodigiosus, consisting of a thousand million bacilli to a c. c., as contained in said barrels was deposited in the Chicago Drainage Canal at the time, and late on the afternoon and evening of the sixth day of November, 1901, during a period of from four to eight hours. Assume further that immediately after the said barrels were emptied into the drainage canal, the laboratories at Lockport, Joliet, Pekin and Grafton on the Illinois River and the intake tower of the St. Louis waterworks, chain of rocks were notified, and that samples were collected at each of these places every hour of the day and night for the purpose of bacteriological analyses for the ascertainment of this bacillus prodigiosus and assume at Lockport these hourly samples, day and night, were taken from November 7th, to November 25th, a period of eighteen days, the total number of samples taken being 432. Assume that at Joliet these hourly samples taken day and night were taken from November 7th to November 25, a period of 18 days, the total number of samples taken being 432. Assume further that at Peoria these hourly samples were taken day and night from November 8th to November 10429 30th, a period of 22 days, amounting to a total of 528.

Assume that at Grafton these hourly samples were taken day and night from November 12th to December 15th, a period of 33 days, the total number amounting to 792, of which 384 were analyzed by Dr. Ravold.

Assume that the total number of samples taken hourly day and night at the chain of rocks was 720.

Assume that at the laboratory tap these hourly samples taken day and night from November 20 to March 1, 1902, a period of 100 days, amounted to a total of 2400.

Assume that the total number of samples analyzed at the different points for the period above mentioned was 5304.

Assume further that on December 4, at 8:45 A. M. 1 bacterium prodigiosus was found at the intake tower at the chain of rocks.

Assume that on December 5th, at 9:00 A. M. 1 bacillus prodigiosus was found at the intake tower, chain of rocks.

Assume that on December 8th at midnight 1 prodigiosus was found at the intake tower chain of rocks.

Assume that on December 6th at 8:00 A. M. at Grafton 1 bacillus prodigiosus was found.

Assume that on December 7th at midnight, at Grafton, 1 bacillus prodigious was found, and assume further that
10430 these five organisms were all the organisms of the prodigiosus that were found in the examination made from Lockport to the intake tower at the chain of rocks and the laboratory tap in the city of St. Louis which were made during the progress of this investigation as hereinbefore set forth and at no time was there more than one single bacterium found at each of these places.

Assuming all the facts as hereinbefore stated to be true, what is your opinion as a bacteriologist as to the value of this experiment as indicating the possible longevity of the typhoid bacillus as measured by the longevity of a bacillus prodigiosus and the probability that a typhoid bacillus entering the drainage canal from the sewers of Chicago would ultimately find its way through the Desplaines and Illinois Rivers to the St. Louis water works at the chain of rocks.

A. Taking into consideration the assumptions as indicated in the question and also considering the question in the light of all the knowledge which I possess with reference to the distribution of the organism known as bacillus prodigiosus under natural and normal conditions, my opinion is that this experiment does not in any way throw any light on the matter
10431 of the probable longevity of the typhoid bacillus as meas-

ured by the longevity of the bacillus prodigiosus, and the assumptions mentioned in the question propounded, leads me to believe it is highly improbable that the organisms reported to have been found on the fourth, fifth and eighth of December at the intake tower, chain of rocks, on the sixth and 7th of December were the same or derived from the organisms which were placed in the waters of the Chicago Drainage Canal at Lemont on the 6th day of November.

This conclusion is based upon the fact that a series of examinations made on the samples taken from the water of the Illinois river at Lockport, Joliet, Peoria and Grafton between the 7th of November and December 15th, amounting in all to 1752, and also samples taken from the intake tower at the chain of rocks, at the laboratory tap in the City of St. Louis, between November 20th and March 1st, amounting in all to 3120 failed to reveal the presence of the bacillus prodigiosus until 28 days had elapsed from the time the cultures were placed in the river at Lemont.

If the organisms which were reported to have been isolated from the waters of the Illinois river at Grafton and the Mississippi at the chain of rocks had been the same or the 10432 progeny of the same as those which were deposited in the Chicago Drainage Canal at Lemont, it would have been natural to expect that in the numerous preceding analyses which had been made, organisms of this species would have been found, as there is reason to believe that the flow of water from Lemont through the Illinois river to the City of St. Louis would not have consumed a period of 28 days.

Assuming that the organisms reported as bacillus prodigiosus, which were found on December 4, 5 and 8th, at the intake tower, chain of rocks, and December 6 and 7 at Grafton, were organisms derived from other sources than those due to the depositing of 107 barrels of cultures of the bacillus deposited on November 6th in the river, and assuming that hourly and daily samples were made at these stations along the course of the Illinois river from Lockport to Grafton, and from the waters of the Mississippi river at St. Louis, said analyses amounting in all to 5304, and assuming that in no case were any organisms belonging to the bacillus prodigiosus found in any of these stations, with the excepiton of the three germs found at the intake tower, chain of rocks, December 4-8, and 2 organisms found in the Illinois river at Grafton on December 6th and 10433 7th, after a period of 28 days after those 107 barrels of culture had been placed in the Illinois river at Lemont, and assuming the well known fact that the bacillus prodigiosus is a saprophytic organism, capable of living in the water under natural conditions a longer period of time than active, vigorous non-spore bearing parasitic bacteria, such as the bacteria of typhoid fever, it is my opinion that the results of the above experiment show that it is highly probable that the saprophytic bacillus prodigiosus had been destroyed in the waters of the Illinois river during the course of its flow from Lemont to Grafton and the City of St. Louis, and, therefore, assuming that such was the case it would be much more probable that the more delicate and easily affected organism of typhoid fever, entering the waters of the drainage canal of Chicago, from the sewers of Chicago, would not have survived a journey down the Illinois river and Mississippi river to the intake tower, chain of rocks, at St. Louis.

Q. What importance do you attach to the experiment as assumed in the hypothetical question?

A. As to throwing light upon the question at issue as to the longevity of the typhoid organisms, I do not consider 10434 the experiment detailed in the foregoing case, where bacillus prodigiosus were placed in the waters of the Illinois river, would be of any direct value, as the selection of this organism would not give conditions which would permit of a proper interpretation of the results obtained.

Q. Are there any other kinds of bacteria resembling the prodigiosus found in this western country?

A. It is not uncommon to find in water and under other conditions in nature, in this region as well as in other places, organisms possessing the characteristic which simulate those belonging to bacillus prodigiosus, by reason of the red pigment which they are capable of producing when grown upon the ordinary nutrient media and which might, therefore, be mistaken for bacillus prodigiosus unless the characteristics of the germs isolated were studied in detail so as to be absolutely certain whether the said organisms belonged to the species bacillus prodigious or not.

Q. Will you give the characteristics and pathogenic significance of the cholera germ?

A. The cholera germs belong to the class known as the spirillum, slightly curved, and therefore receive the name of comma bacillus, on account of its resemblance to the
10435 character comma. This organism is capable of growing on artificial media readily. On nutrient gelatine it is able to liquefy the gelatine, producing a characteristic appearance, both on gelatine plates and in gelatine culture. This is characterized by the formation of gas by products which are rapidly volatilized, causing the formation of a sharply defined pit, in the bottom of which the developing colony is to be noted. The organism upon agar is not especially characteristic. It grows under both aerobic and anaerobic conditions. It is capable of reducing nitrates to nitrites and possesses the well known and well characterized cholera red reaction which enables it to be readily distinguished from other spirillum. It is capable of producing toxic products which are able to produce fatal results in the bodies of experimental animals under certain conditions, although not normally doing so by ordinary means of inoculation.

Q. Of the tetanus germ?

A. The tetanus germ is a bacillus, spore bearing, producing a spore much larger than the mother cell, and therefore giving a drum head appearance to the organism in micro-
10436 scopic examinations, which is very characteristic. The germ is a strict anaerobe, therefore does not develop on ordinary nutrient media, exposed to contact with air. It is capable of growing in artificial media, in the presence of hydrogen or nitrogen, producing in gelatine cultures a very characteristic radiating growth which resembles an inverted fir tree. The germ is capable of producing a very powerful toxin which in exceedingly small quantities produces fatal results in laboratory animals.

Q. Of the anthrax germ?

A. The anthrax germ belongs to the bacillus group, is a very large organism for bacteria, square ended, spore bearing, grows readily upon artificial media; presents in gelatine a well characterized appearance; on agar, less distinct, causes the death of most kinds of laboratory animals upon inoculation of exceedingly small quantities of culture.

Q. The enteriditis sporogenes?

A. Bacillus enteriditis sporogenes is an organism which was discovered by Klein of England. He found it particularly common in sewage and waters polluted with fecal material. This organism is an anaerobic germ, spore bearing, capable of growing upon ordinary culture media; possesses char-
10437 acteristic appearance in milk which enables it to be readily recognized; is toxic for laboratory animals, although it is not usualy associated with disease conditions in man.

Q. Of the dysentery bacillus?

A. The dysentery bacillus is the organism which was discovered by Shiga in Japan, in cases of Japanese dysentery. It has also been recently found by Kruse in Germany, and Flexner in the Phillipines, both of whom have associated it with the production of bacillary dysentery in man. The organism is somewhat allied to the typhoid organism or the colon bacillus. It possesses culture characteristics more nearly related to the typhoid than any other important bacterial form, although it is readily distinguished from the typhoid organism by its reaction towards glucose sugar.

Q. Have you made any special study of the typhoid germ?

A. Yes, sir.

Q. Give the characteristics of the typhoid germ?

A. The typhoid organism belongs to a group of bacteria which is sometimes called the typhoid colon group. The
10438 organism is a germ capable of growing both in the body of animals and in artificial media. On gelatine it is incapable of liquefying the media. Surface colonies present an irregular contour, bluish gray by transmitted light, giving a peculiar lustre, which is quite characteristic on certain media. The organism grows well on agar, in colonies, producing, however, no marked change in the physical properties of the colony. It grows well in broth to which sugar is added, and in these media can be readily distinguished from the varieties of the colon group.

Q. Where are typhoid germs found.

A. Typhoid organisms are found, of course, in cases of typhoid fever, thriving and growing in the intestinal tract, in the lesions produced in the intestinal wall, spreading from thence into the interior tissues of the body where it is found most frequently and in largest numbers in the spleen. It is located in other portions of the body during cases of the disease and may even retain its vitality after convalescence. The organism appears in the feces and the urine of the typhoid patients and retains its vitality in these materials for varying periods of time after the same have been voided from the living host.

10439 Q. What germs do they resemble?

A. The species of bacteria included under the head of the typhoid germ closely resemble a number of other bacteria, not only morphologically, so far as form and structure are concerned, but also as to certain characteristics which they possess similar to other related organisms growing on ordinary nutrient media.

Q. Is it related to the colon bacillus, and if so, in what way?

A. The germ of typhoid fever belongs to a group of organisms which includes, in addition to this specific organism, other bacteria such as bacteria coli communis, or the colon bacillus, and also other bacilli which stand intermediate between the colon bacilli and the typhoid fever organism, which are known as the para colon and the para typhoid organism. The typhoid organism is, therefore, related to the colon bacilli, such relationship being expressed by the morphological similarity of the two organisms as to form and structure, size and arrangement of cells and in a number of growth characters, as exhibited by both organisms when grown on artificial media.

Q. What methods are employed for determining and identifying the typhoid bacillus?

10440 A. The determination and identification of the typhoid organisms is made by isolating the presumptive organism in pure culture from various sources and then transplanting these in various nutrient media in which the organism grows and develops, producing thereby characteristic by products, some of which are peculiarly specific to this organism and permit of its differentiation from other closely related organisms. Such differential tests may be applied as the growth of the typhoid bacillus in milk, to which litmus is added. Its growth in broth to which lactose is added. Its growth in a broth when litmus and dextrose is added, when the acidity of the media is increased by reason of the fermentation which is produced in the added glucose; also recognized by its inability to liquefy gelatine and produces colonies which are more or less characteristic, and is especially recognized by its power to cause an agglutination or a clumping of the blood serum of animals which have been artificially immunized against the typhoid bacillus by repeated injection of cultures of such bacilli in the body cavities of animals.

Q. Please give the longevity of the typhoid bacillus in the human body?

10441 A. The typhoid fever organism grows and multiplies in the human body, and is capable of retaining its vitality even after convalescence for a considerable period of time, as is shown by the continued excretion of the organism in the urine of patients, for weeks and sometimes even months after the disease has run its course, and still longer as has been shown by the isolation of the typhoid fever organisms from portions of the body such as the bone marrow where it has been found in a few cases even years after the disease had disappeared.

Q. Please give the longevity of the typhoid bacillus in soil?

A. The typhoid fever organisms is capable of retaining its vitality in soil for a varying period of time, depending upon the influences to which it is subjected and its environment. When deposited in the soil by burial, the organism rapidly loses its vitality so that at the expiration of a short period, measured by a few days, it can no longer be detected in the upper layers of the soil. When the soil is moist and the organism is deposited in typhoid dejecta, the germ is capable of retaining its vitality for a longer period of time, a period of time which may be measured by months. Some experiments indicate a retention of vitality for five or six months.

10442 Please give the longevity of the typhoid bacillus in water?

A. The longevity of the typhoid bacillus in water is materially shorter than it is under soil conditions, and here again depends largely upon the conditions of exposure. Where the organism is brought in contact with an aqueous medium with normal saprophytic bacteria, such as would naturally be found where the organism was exposed in sewage or polluted waters, the vitality of the typhoid germ is greatly impaired, and its longevity is thereby lessened, so that it is my opinion that under such conditions in waters of this character, the longevity of the organism would not normally be more than three or four days or so, but that in waters of a greater degree of purity where saprophytic bacterial life is not so abundant and therefore the vital concurrence between these native bacteria and the typhoid organisms would not be so great, the longevity of the typhoid organisms, under these conditions, would be increased so that it might be found in waters which would ordinarily be deemed as pure waters, even at the expiration of a longer period, possibly one or two weeks.

Q. Have you made any experiments upon the longevity of the typhoid bacillus in different kinds of water?

A. Yes, sir; I have carried out an extensive series of experiments in connection with this matter of the longevity of the typhoid organism. These experiments indicate that when the organism is exposed in water which is ordinarily pronounced as pure and which has first been sterilized by heat and thus deprived of its germ life and possibly of metabolic products of bacterial activity, this process changes the conditions of the water so that in these waters the germs of typhoid fever are capable of retaining their vitality for a period of time, measured by months. 10443

I have also conducted experiments where such water was deprived of its bacterial life by filtraton rather than by heat, and under conditions where the soluble products of bacterial growth in the water would be brought in contact with the typhoid organism.

Q. Please give the results of those experimnets?

A. The results of these experiments which have been made with waters sterilized by these two processes of heating and filtration indicate consistently that the vitality of the typhoid organism in raw water rendered sterile by filtration was considerably shorter than in the same water which had been rendered sterile by the application of heat. These results obtain not only where the amount of typhoid organisms which were seeded were even light, but also where large numbers, 10444 several thousand per loop, were inoculated. The results of these tests were uniform and indicated that without exception the vitality of the typhoid organism in such raw waters as these was much shorter than in water sterilized by heat.

10445 Q. Does the typhoid bacillus multiply and increase in nature?

A. So far as my experience goes, it is not my belief that the typhoid organism is capable of multiplying and increasing outside of the body under a natural condition. At least this is not the case so far as its relation to water is concerned, and the general opinion among investigators upon this subject is that when discharged with fecal material upon the surface of the ground it is exceedingly questionable whether there is any growth when brought in contact with soil bacteria.

Q. Are the conditions of laboratory experiments more or less favorable than the conditions in nature for the longevity of the typhoid bacillus?

A. The conditions in which laboratory experiments have been performed on the longevity of the typhoid fever organism, are, as a rule, more favorable for the prolongation of vitality of this organism, than would exist where the organism was exposed under natural conditions.

Q. What reason have you for this opinion?

A. This opinion is based upon the well known fact that when the typhoid organism is exposed under natural conditions, in, for instance, flowing waters, it is subjected to a number of factors of a detrimental character, exerting a detrimental influence which often can not be readily simulated under laboratory conditions, and which in the case of the laboratory experiments that have been published relating to the longevity of the typhoid bacillus, in many instances no attempt has been made to overcome. 10446

Q. Will the germ of typhoid fever live as long in polluted water as in pure sterilized water?

A. It has been recognized by practically all investigators on this subject that the organism of typhoid fever lives longer in sterilized water than it does under raw conditions and if such waters are polluted, if normal raw waters are polluted, it is my belief that the longevity of the germ would be much less than in the case of purer sterilized water.

Q. How do you account for this?

A. My opinion that the typhoid organism will not live as long in polluted as in pure waters which have been sterilized by heat, is based upon the fact that there exists an antagonism between the saprophytic bacteria, found in polluted waters, or the bi-products of the growth of these organisms and the typhoid organisms, which exerts a prejudicial effect upon the
10447 development of the typhoid germ, thereby diminishing its vitality and shortening its longevity.

Q. From your knowledge of the quality of the water in the drainage canal, the Desplaines river and the Illinois river, what is your opinion as to the longevity of the typhoid bacillus in those waters?

A. From my knowledge of the conditions which obtain in the water of the Chicago drainage canal and the Illinois river my opinion is that the longevity of the typhoid organism would not be beyond the average more than a few days, at the most, say three to four days.

Q. How do you account for your assumption that the life of the typhoid in the waters of the Illinois river and drainage canal and Desplaines river is shorter as compared to the laboratory experiments?

A. The reason assigned for the diminished vitality of the typhoid organism in the waters of the Illinois river in comparison with those which have been reported in laboratory experiments, is, that under the conditions under which the organism is exposed, in said stream, the germ would be subject to
10448 a number of environmental influences which would exert a prejudicial effect upon the vitality of the organism, and would thereby shorten the longevity of the germ to a period much shorter than would be found in an experimental test carried on in the laboratory conditions where the influence of these detrimental factors was more or less excluded.

Q. Have you made any experiments on the competition existing between the typhoid and the saprophytic bacteria?

A. Yes, I have made a large number of experiments on this very matter, of the vital concurrence or competition which would exist when the typhoid organism was exposed under artificial conditions to the influence of various saprophytic bacteria.

Q. Please state these experiments in full?

A. These experiments have covered a period of four or five years and have been conducted along a variety of lines. One group of these experiments have been made, where cultures of the typhoid organism were placed in celloidin sacs, which were germ tight and therefore would not permit of the passing out of the typhoid organism or the passing in of any extraneous organism, but which will permit of the passing in and
10449 out of the soluble products of the growth of these organisms. These sacs were placed in cultures made of nutrient material, to which material was added such as soil, water, and other matter containing divers forms of saprophytic bacteria. Under such conditions bacterial growth was of course abundant in the outside medium. The results of such experiments indicated frequently that the typhoid organism was unable to grow on the inside of these sacs, even when placed in nutrient medium, such as beef broth. In many instances not only was this inability to grow marked, but the organism was actually killed off. Further experiments have been made to isolate from these impure cultures, the organisms on the outside of these sacs which were capable of bringing about this change. It was possible to demonstrate in this way that there were a number of saprophytic bacteria such as the bacillus flourescencens liquefaciens, a well recognized and well known common water bacterium, that possessed the power of exerting an antagonistic effect against the typhoid organism to such an extent that the typhoid germ placed in nutritive medium inside of the sacs, was incapable of growth. Under such circumstances the typhoid germ itself was only brought in contact with the soluble products of the growth of the saprophytic water
10450 bacteria, which were capable of passing this permeable membrane. The fact that under such conditions the organism lost its vitality, indicates to my mind a specific illustration of the law of antagonism which is konwn to be operative with various organisms among the bacteria and which is undoubtedly a potent agent in the destruction of pathogenic bacteria in the outside environment.

Further experiments have been made where the typhoid

organism has been grown in normal waters, which have been rendered germ free by the processes of sterilization and filtration. In such cases the longevity of the typhoid germ is always shorter in raw water which has been rendered germ free by filtration, than it is in the same water which has been rendered germ free by sterilization. The process of sterilization by heat destroys in all probability certain toxic or prejudicial substances which are naturally present in waters where bacterial growth has previously existed. The direct antagonism between the typhoid organism and certain saprophytic bacteria was shown
particularly well in my judgment in a series of experi-
10451 ments in which boiled water was taken and inoculated
with the colon organism, and also one other well known water bacillus, the flourescence bacillus before mentioned. After these organisms had thrived and grown in boiled water they were then rendered germ free by filtration. This deprived the water of the bacteria themselves but left in the water the soluble products that had been produced by these organisms which were capable of passing the filter. Such filtered waters were then inoculated with typhoid organisms of varying strains, of varying age, with varying amounts, and it was observed that in a large proportion of the cases the typhoid organisms so inoculated into these waters which had previously supported the bacteria life of the saprophytic class, resulted in the early destruction of the typhoid germs. In fact, in two or three days time. Whereas, the same strains of the typhoid organism of the same age of culture in varying amounts similar to those that have been used in the other experiments were inoculated into the same kind of water which had been previously boiled, but which
had not been seeded with these saprophytic organisms.
10452 In these cases the typhoid organism lived longer. The
results of these conclusions lead me to believe that there exists in nature a direct antagonism between various saprophytic bacteria which are normally to be found in water, and the typhoid organism, and that such antagonism results in the loss of vitality of the typhoid germ very much more rapidly than would be the case if the typhoid organism was not exposed to such a prejudicial environment.

Q. Are there any other experiments aside from those you have detailed, which you know of, or have made yourself, touching upon the longevity of the typhoid as compared with the life of other bacteria?

A. These experiments which I have just detailed were not only made by myself, but have been investigated by a number of my advanced students working under my direction and the results have been confirmatory in a general way. The discrepancies in the results, being no more than I would naturally expect would occur where different observers have worked at different times under slightly different conditions.

Q. Are you acquainted with the physical conditions of
10453 the drainage canal, the Desplaines river and the Illinois
river, and the Mississippi from Chicago to St. Louis?

A. I have had an opportunity of examining into the physical conditions of the Chicago drainage canal, the Desplaines river, the Illinois river and the Mississippi river.

Q. Will you describe the dams in the Illinois river?

A. In the trip which was before mentioned I had an opportunity of seeing the dams which have been placed in the lower reaches of the Illinois River, and was able to note the effect these dams would produce upon the physical appearances of the river.

Q. What effect did those dams have upon the problem of sedimentation?

A. The rate of flow in the lower reaches of the Illinois river is much slower than in the upper, causing the river to spread out over a wider cross-section. The damming up of this stream through the construction of the dams on the various points of the river, widens still further the body of water in the river, causing slack water to exist for a considerable distance back to the extent that the height of the dam would
equal the normal fall of the river. As the fall per mile
10454 in the lower reaches of the river is relatively low in comparison to what it is in the upper portion, this damming
back of the stream of low water must amount to considerable. This retarded rate of flow of the current reduces the carrying power of the stream, as to the transportation of the suspended material, and thereby produces marked sedimentation. The subsidence of this matter carries down to the bottom of the stream much of the bacterial life which is present in the river,

thus purifying the water of the river, of its bacteria as well as relieving it of its suspended load of sediment.

Q. How is sedimentation in the Illinois river affected by the higher and lower stages of water?

A. At low water, where the flow is small, the result of the dams must produce slack water to a certain extent, causing sedimentation. At high water the load of suspended sediment in the river is a great deal increased owing to the eroding effect of the surface run off on the land. This increase in the amount of the load carried, naturally increases the possibilities of sedimentation, where there are no variations in the rate of flow of the current. As the flow per mile diminishes from the upper to the lower reaches of the river, the current is naturally retarded and thus has a tendency to deposit
10455 its load. On the contrary, the larger volume of water found in high water increases the rate of flow and tends to retard this rate of deposition.

If the river rises to high stages, where the banks are overflowed, which condition would easily be possible, as the Illinois river flows through a relatively low plain, the water spreads out over the banks and causes deposition by sedimentation.

On the trip taken in September, I noted locations where the water was several miles wide. These locations I would consider as giving favorable opportunity for the production of slack water to a greater or less extent and would therefore permit of the marked deposition of the suspended matter which might be present in the stream.

Q. Will bacteria respond to the law of gravity in the pure water of the running stream?

A. The specific gravity of bacteria is only a trifle above that of water. Hence the sedimentation of bacterial cells themselves cannot well occur in pure water freed from all insoluble sediment except in a state of absolute quiescence.
10456 In this connection I have made a large number of experiments on the vertical distribution of bacteria in lakes such as Lake Mendota, at Madison. In the winter when the lake is covered with ice, and therefore there are no disturbing currents due to wind action and temperature changes, the results of these experiments show that the upper layers of the water, although entirely free from sediment contain a rela-

tively large amount of bacterial life and in fact I am unable to ascertain that there is any material settling out of germ life by mere gravitation in waters which are pure, even in a quiescent condition, and much less so in that of a running stream.

Q. What is it that causes bacteria to settle at the bottom of a running stream?

A. The reason why bacteria settle to the bottom of a flowing stream depends not on the sedimentation of these organisms themselves, but on account of the subsidence of suspended matter in the stream. The small soil particles, which constitute the mud and silt found in running streams, carry
10457 down with them as they fall to the bottom of the stream,
a large part of the bacteria which may be found in such waters. In this way the germ content of the muddy water may be very greatly reduced by the sedimentation of its suspended load.

Adjourned until 2 P. M., the same day, February 18th, 1904.

10458 2:00 P. M., Thursday, February 18, 1904. Continuation
pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

PROF. H. L. RUSSELL

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Could sufficient water from Lake Michigan be carried through the drainage canal into the Desplaines and Illinois Rivers to create a condition of purity and clearness so as to preclude the operation of sedimentation in the Illinois River?

A. I am not familiar with the conditions well enough to know the maximum amount of water which it would be possible to pass through the drainage canal into the Illinois River but I think it extremely improbable that if all the sewage of the City of Chicago was discharged into said drainage canal that a sufficient amount of pure water could be discharged through this channel so as to produce a condition in the waters of the
Desplaines and Illinois Rivers which would preclude the
10459 operation of sedimentation in the latter stream.

Q. Assuming that the entire sewage from the city of Chicago should be diverted into the drainage canal and that one million cubic feet per minute should pass over the Bear Trap dam at Lockport, would that amount of dilution be sufficient after it reached the Illinois River, mingled with the sewage of Chicago, to so separate the matter in suspension in the Desplaines and Illinois River, as to prevent the operation of sedimentation of bacteria?

A. Assuming the present rate of flow to be somewhere in the neighborhood of 300,000 cubic feet per minute with the present amount of sewage discharged, and a condition of turbidity and sediment equal to that reported as existing in the sewage at the time of the analysis as made by Professors Jordan, Palmer, and Gehrmann, and reported in Streams Examination, I do not consider that an increase in the amount of Lake Michigan water to a point that would equal a discharge of a million cubic feet per minute over the Bear Trap Dam, would permit of entire separation of the suspended matter which would be present in the waters of the drainage canal to such a point that the dilution would prevent the sedimentation of such material and the consequent removal in part of the bacterial life in the water.

10460 Q. What sanitary significance does dilution have in considering the process of the problem of self purification of streams?

A. The increase in the volume of water noted in the flow of any stream is due to two causes. First, the water received from surface tributaries which constitute the so called run off from the surface of the land; second, the volume of water which comes from the percolation of the water directly through the soil, seeking a lower from a higher level, and therefore appearing in the drainage channels, either in the form of springs or oozing through the ground. This flow, known as the dry weather flow of a stream, together with the water which finds its way over the surface of the soil, are both factors which cause dilution in a stream, through an increase in the amount of water. The water contributed by the first factor is water which is rich in germ life of a saprophytic nature and those organisms present in the surface of the soil.

The water contributed in the second case is the ground

water supply which has been deprived almost if not entirely of its germ contents by filtration through large or smaller masses of soil, and the introduction of this comparatively sterile water would, therefore, greatly reduce the germ content in any
existing body. Whenever the possibility of disease bac-
10461 teria is present, the admixture of this relatively germ
free ground water, or even the surface run off, diminishes the number of disease organisms materially which would be present in any given body, although it might contribute in a considerable measure numerous water bacteria. The dilution of any polluted water therefore with waters coming from these sources would thereby greatly diminish the danger of contracting disease through the introduction of pathogenic bacteria.

Q. Is the danger of infection entirely diminished by dilution?

A. The infection of the human system from disease bacteria undoubtedly requires in some cases a simultaneous introduction of more than one specific organism of any disease. When water which is infected with disease bacteria is therefore diluted with water not containing these organisms the danger of infection which might arise from the ingestion of such water is really diminished, as the case of a given quantity of such water would permit of the absorption of a smaller number of those specific organisms connected with that disease, and it is entirely conceivable that in this way the amount of water which would be taken might contain less than the lethal dose.

Q. Is it a fact that the greater the dilution of sewage the
10462 less the danger from infection?

A. On the assumption that the danger of infection from sewage comes from the presence of pathogenic bacteria which find their way into the sewage from the fecal discharges, it is true that a dilution of sewage containing those organisms would diminish the number of bacteria of a specific kind, capable of bringing about this infection, and when it is further assumed that it is probably necessary in the case of intestinal diseases that there shall be a simultaneous introduction of more than one organism of a specific disease such as typhoid fever, it therefore follows that the dilution of sewage may reach a point where the danger of infection from sewage which might origially have been dangerous would be brought to such a point as to be relatively harmless.

Q. What effect does the dilution of the Chicago sewage with the water of Lake Michigan have upon the conditions of the water in the Illinois River?

A. The dilution of the Chicago sewage, as found in the drainage canal, with the purer waters coming from Lake Michigan would result in a diminution of the number of disease bacteria which might be present in Chicago sewage in any given volume, and would thus greatly minimize the danger of 10463 infection which might come through the ingestion of the water taken from the Illinois River.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois River, considered from the standpoint of dilution alone?

A. If we consider this question from the standpoint of dilution alone it is evident that the addition of water from Lake Michigan, relatively low in germ content and of a very much purer quality than would exist in the sewage as found in the drainage canal at Chicago, then the addition of this water would be a benefit to the sanitary condition of the water as found in the Illinois River.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois River, considered from the standpoint of chemical and bacterial changes taking place?

A. The addition of the waters of Lake Michigan to the sewage of the City of Chicago undoubtedly alters the sanitary condition of the waters of the Illinois River in that it dilutes a very impure and polluted water with waters of a much higher degree of purity. This must of necessity modify 10464 the conditions which would obtain from the standpoint of the chemical and bacterial changes which would take place in the upper regions of the river.

Q. If a sufficient volume of Lake Michigan water should be added to the sewage of Chicago so as to cause the elevation in the waters of the Desplaines and Illinois Rivers, what effect would this increased volume of water have upon the question of sedimentation in the Illinois River?

A. If a sufficient volume of water, Lake Michigan water, should be added to the sewage of the City of Chicago and discharged in the waters of the drainage canal, so as to cause an elevation in the waters of the Desplaines and Illinois Rivers to such an extent as would lead to the overflow of the low lands adjoining these rivers, this increase in the volume of water would undoubtedly facilitate the sedimentation of the suspended matter in such localities where this slack water existed.

Q. How does the physical condition of the Illinois River compare with the other rivers of the country, for the purpose of purification and sedimentation?

A. On account of the fact that the banks of the Illinois
10465 River are relatively low it is therefore possible at high
water stages for these banks to be easily covered and the widening of the stream during such stages of high water would lead necessarily to a retardation of the current and so cause to be deposited on these low lying lands much of the sediment which would be present in the stream and so would lead to a material sedimentation, and by reason of this fact to a material purification of the water in the Illinois River, when compared with other rivers in which the elevation of the shore was such as to prevent the ready overflow of their banks.

Q. From your knowledge of the physical conditions that obtain along the Illinois River as well as from the results of the analysis of the waters, both chemical and bacterial, as they appear in Streams Examinations, what effect, if any, does the sewage from Chicago, discharged into the drainage canal, have upon the waters of the Mississippi, as the same passes along the shore of the state of Missouri?

A. Taking into consideration the conditions which obtain in the Illinois River as to the sedimentation and dilution, and all other conditions that can be observed, which permit of the
production of chemical and bacterial changes in the sew-
10466 age, as revealed by the analyses reported in Streams Ex-
aminations, I do not consider that the sewage of Chicago, as discharged into the drainage canal, can have any material effect upon the waters of the Mississippi River except possibly to increase the amount of such undissolved salts as chlorine which are not taken out of solution and which would therefore find their way down the stream and thus probably

increase the chlorine content of the waters of the Mississippi River as they pass the shores of the State of Missouri.

Q. What is your opinion as to whether any pollution, dangerous to public health, entering the drainage canal from the sewers of Chicago, reaches as far down the Illinois River as the town of Grafton?

A. Basing the results which have been recorded on the self-purification of flowing streams on the fact that the typhoid organism does not thrive in natural waters, and it is only a question of how long it will live in waters of this class, that the time of flow is so great that pollution dangerous to public health would cease to exist in sewage passing from the city of Chicago to the Illinois River, down as far as the town of Grafton, from
the fact that experimental evidence shows that the ty-
10467 phoid organism will not live in highly polluted waters
like those of the drainage canal and upper portions of the Illinois River for more than a brief period of time, measured by three or four days, my opinion is that any pollution which would be dangerous to public health which might arise from the sewers of Chicago and enter the drainage canal would not exert any influence on the character of the waters of the Illinois River at its mouth, at the town of Grafton.

Q. What evidence have you that justifies the conclusion just expressed that no pollution dangerous to public health, coming from the sewers of Chicago, reaches as far down the Illinois River as Grafton?

A. The evidence which can be adduced for the justification of the conclusion just expressed rests upon an experimental evidence which has been adduced, which shows that organisms capable of causing typhoid fever will not live in the waters of the Illinois River for a sufficient period of time so that it would have been possible for them to have been carried from the sewers of the city of Chicago down the Illinois River as far as Grafton.

Q. What is your opinion as to whether any infectious matters coming from the sewers of Chicago, by way of the drain-
age canal, in a dangerous state reach as far down the
10468 Illinois River as the city of Grafton?

A. My opinion is that any infectious matters which may be discharged from the sewers of Chicago by way of the drainage canal, are deprived of their infectious properties by reason of the conditions which exist in the waters of the drainage canal and in the waters of the Illinois River before they have had time to have been carried by the waters of said stream from the city of Chicago down through the drainage canal and the Illinois River to the city of Grafton.

Q. Is there any evidence, bacterial or chemical, that you know of that would justify the conclusion that polluted and infectious matter coming from the sewers of Chicago would reach as far down the Illinois River as the town of Grafton.

A. I have no knowledge or any data whatever of a chemical or a bacterial nature that would justify the conclusion that the pollution brought through the sewers of Chicago to the drainage canal and thus finding its way down the Illinois River would be brought as far down that river as the town of Grafton, in a condition where it could be dangerous.

Q. Would the condition of low water in the Missouri River at a time when there was high water in the Illinois River
10469 be in any way a factor in carrying infected and polluted matters from the sewers of Chicago to the city of St. Louis?

A. If the typhoid fever organism is destroyed under natural conditions which obtain in the Illinois River, in the course of three or four days, the stage of water in the Missouri River and the Mississippi River would exert no effect as I can see on the carrying of infected or polluted water from the city of Chicago to the city of St. Louis.

Q. Professor Sedgwick, in answer to this question, on page 3545 of the record which I have, "Professor, will you state whether or not it is within the bounds of human possibility for any competent expert to say that in the period of low water on the Missouri River, such as is likely to occur at next Christmas time a thaw on the Illinois River waters shed might not endanger the lives of the people using the waters of the Mississippi below the mouth of the Illinois on the Missouri shore and at the city of St. Louis by sending to them in that water the suspended sewage of the sanitary district of Chicago," answered: "I do not believe that it is because in my opinion no

competent expert either can or will say that any means
10470 exist at present by which such unpurified sewage can be
warded off from the people on the Missouri shore and the citizen of St. Louis, under those conditions." I will ask you to state what is your knowledge in regard to the assumption that low water might exist in the Missouri at a time of flood water in the Illinois, and also state whether you know of any means existing in the Illinois River at present that would permit unpurified sewage from the city of Chicago to become a danger and a menace to the public health of the citizens of Missouri and the citizens of St. Louis?

A. From the knowledge which I have of the conditions which would exist if infected and polluted matters entered the drainage canal at Chicago and found their way down through the drainage canal, the Illinois River and the Mississippi River, I would say that I do not regard the assumption that low water might exist in the waters of the Missouri simultaneously with the existence of flood waters in the Illinois would have any effect upon the waters of the Mississippi as would exist at the city of St. Louis so far as the presence of infected and polluted matter derived from the city of Chicago was concerned. Also that the conditions which exist in the waters of the drainage canal and in the waters of the Illinois River under natural
10471 conditions would be such as to destroy infectious matter
capable of producing a disease, which were discharged into the waters and which originated from the sewers of the city of Chicago and that therefore it would be highly improbable that any unpurified sewage from the city of Chicago would pass through the waters of the drainage canal down the Illinois River and Mississippi River and reach the water supply of the city of St. Louis, which would be a danger and a menace to the public health of the citizens of that city.

Q. Professor, from your knowledge of all the conditions that obtain along the Illinois River, as well as your knowledge of the conditions that obtain in Chicago and the drainage canal, also your knowledge of the water supply in St. Louis, such as is had from the intake tower at the chain of rocks, what effect does the sewage from Chicago have upon the water supply of the city of St. Louis or upon the waters of the Mississippi River, as it passes along the state of Missouri?

A. From the knowledge which I have gained with reference to other conditions which exist in the waters of the Chicago drainage canal and in the waters of the Illinois River, together
with the evidence which has been presented as to the
10472 degree of purification which obtains in that stream, as
reported by the chemical and bacteriological examination made of the waters of the drainage canal and Illinois River and the Mississippi River, down to the intake tower at the chain of rocks, at the city of St. Louis, I do not consider that the introduction of the sewage of Chicago into the drainage canal exerts any deleterious effect upon the water supply of St. Louis or upon the waters of the Mississippi River as they pass the State of Missouri.

Q. Please state upon what facts you base your opinion that a typhoid bacillus will not live more than three days or four days under the conditions as they obtain in the Illinois River?

A. The conclusion that the typhoid organism will not live in the waters of the Illinois River for more than a period of three or four days is based upon an extensive series of experiments which were arranged and planned for conjointly with Professors Jordan and Zeit and myself, but carried out independently. These experiments were designed to show how long freshly isolated typhoid organisms would actually live under conditions as they obtained in the drainage canal and in the waters of the Illinois River.

Q. Please give the full details of the experiment made
10473 by yourself, as indicated in the foregoing question and
answer?

A. The experiment was planned at the time that a number of scientific men made the trip from the city of Chicago through the drainage canal, down the Desplaines and Illinois and Mississippi Rivers to the city of St. Louis. It was deemed advisable at that time to make an actual test of the conditions as obtaining in the waters of these rivers, as to just how long typhoid fever organisms would be capable of maintaining their vitality, when exposed to the waters of these rivers under as nearly natural conditions as were compatible with experimental methods. This experiment was planned by Professor Jordan of the University of Chicago, Professor Zeit of the Northwestern University and myself. The work was planned in detail and to each one of the respective parties was assigned certain particular steps to take in the experiment, each one assuming the responsibility for the individual part of the experiment under his own control.

It was designed to expose the typhoid organism to the waters as found in Lake Michigan and in at least three points in the waters along the Chicago River and Drainage 10474 canal, and at least one point along the course of the Illinois River. For the purpose of determining what relation the varying conditions of the water as found in Lake Michigan, Chicago River, drainage canal and the Illinois River would exert upon the mortality of the typhoid organism. The matter of detail and methods was thoroughly discussed at the time this trip was taken and it was decided in order to remove the possible objection which might come from the use of the laboratory stock cultures such as would be found in various bacteriological laboratories the virulence of which might be possibly attenuated to a greater or less degree through their cultivation upon artificial neutrient media for a varying period of time that it would be preferable to employ for the purpose of this experiment strains of the typhoid organisms which had been freshly isolated from the body of patients who were suffering from the disease of typhoid fever.

In order to remove the possible objection which might be urged against the use of merely one strain of the typhoid organism with a knowledge that there is under natural conditions some fluctuations in the virulence and possibly the vital- 10475 ity of different strains of the typhoid bacillus, it was deemed advisable to repeat these experiments and for this purpose said experiments were performed not with merely one culture but with three cultures which were freshly isolated from bodies of persons suffering with typhoid fever, and the use of which would therefore remove any possible objection which might exist, if such experiment had been performed upon only one strain of this organism.

During the time of this trip, when these arrangements were being made, the matter of technique was thoroughly discussed, and it was deemed advisable that in order to remove the objection which might be made to independent experiments conducted by different persons with culture material of possibly varying composition, it would be preferable for the work as outlined to be done in as nearly the same manner, so far as technique was concerned, and upon the same batch of culture material, so far as practicable.

With reference to the detail of the experiment it was decided that Professor Zeit should carry on the experiments in which the typhoid organism was exposed to the waters of Lake Michigan and the waters of the Chicago River; that Professor Jordan would carry on the experiments in at least 10476 two places in the waters of the drainage canal, and for that purpose it was decided to select the entrance and the end of the drainage canal; that I should carry on co-ordinate experiments in the waters of the Illinois River at such point as would represent the greatest possible degree of purification that would be likely to be found.

This variation in conditions of exposure of the typhoid organism was made on the assumption that if the organism was exposed in waters ranging all the way from the strongest concentration of sewage as found in the waters of the Chicago River and at the entrance of the canal, to the point of the greatest degree of purification which could be found in the waters of the Illinois River, and also with the pure waters of Lake Michigan, that this variation in conditions of exposure would be such as would produce the greatest possible range in the results as to the longevity of the typhoid fever organism, when exposed in such waters.

In accordance with this understanding the series of experiments which were allotted to myself were carried out 10477 at the city of Peoria where the conditions of exposure at Averyville were such as was deemed to show the most completely purified stage of the waters of the Illinois River.

For the purpose of this test a laboratory was established at the Bradley Polytechnic Institute, and an assistant placed in charge under my direct supervision for carrying on the detail of this work.

The waters which were infected with the typhoid culture were withdrawn by my assistant and plated out, cultures being taken therefrom and shipped by express to me at Madison, for further study. The cultures which were used in this experiment at Peoria were received by me from Professor E. O. Jordan, and was designated as culture typhoid X, typhoid Y and typhoid Z.

The technique of the experiment was carried out in the following manner:

Recognizing the difficulties which have heretofore obtained in experiments of a similar character in which the typhoid organism was tested as to its longevity in various waters
10478 where such experiments have been conducted in closed vessels made of glass, recognizing the fact that the conditions of such experiments do not accord with the conditions to which the typhoid organism would be exposed when deposited in the waters of a flowing stream, it was deemed necessary to secure information which would present the conditions that would actually obtain when such organisms were exposed in running water and the method was therefore devised of exposing the typhoid organism under such conditions as would permit of the establishment of a state of affairs which would be more nearly in accord with those which existed in the flowing stream. For this purpose a method was used which I had devised and used in similar work in preceding years, where cultures of bacteria could be exposed in permeable sacs which would permit of the ingress and egress of soluble substances on either side of this permeable membrane.

For the purpose of this experiment large parchment sacs were employed, the cubic content of which could be varied at will and could be entirely closed so as to prevent the leakage of bacteria from the inside toward the out or vice versa, but which would permit of the osmotic action of any
10479 soluble substances either to the inside or outside of this permeable membrane. In this way it was expected that many of the defects which have heretofore obtained in experiments which have been made in closed vessels constructed of glass would not obtain where the conditions of the experiment were such as to permit of this free osmotic action. At the same time the conditions of the experiment precluded the possibility of particulate substances such as bacteria from passing either in or out. The conditions then under which this exposure was made was to fill these sacs with water taken from the point in the river where the sacs were to be later immersed, and added to

this volume of water placed in these sacs varying quantities of fresh cultures from these freshly isolated typhoid organisms. In this way the typhoid organism would be subjected to the same conditions as would obtain in the river. The conditions were identical with those which would obtain in any given quantity of river water equal to the capacity of the sacs. If any deleterious effect was to be observed on the typhoid organism due to growth and development of water bacteria which are more habituated to this environment, it would impose itself upon the imprisoned tphoid organisms if the experiment were kept under such conditions as would permit of their isolation.

10480 After some experiments were performed in which the parchment sacs were exposed in the waters of the river in a partially submerged condition, which experiments came to naught through the breaking of the sacs, and the surrounding floats from their moorings, on account of the high winds which existed at such times as when the wind was blowing up the river, it became necessary to vary the original plan of the experiment and entirely immerse the sacs which were filled with river water and inoculated with typhoid bacillus. It was therefore necessary to close the upper opening of these sacs in such a way as to permit of easy access so that samples of water could be removed at intervals for subsequent examination. This was done by making the sacs longer than they would ordinarily be made and folding the same back and forth for at least eight times, placing between the same pieces of soft wood, and binding down this folded parchment by means of strong clamps, slightly wider than the tube on which they were placed. This permitted of the complete immersion of the parchment sac with the opening of the sac closed so tightly that water could neither pass in nor out.

10481 The difficulty of recognizing the typhoid organism when growing in competition with the ordinary water bacteria which are found so abundantly in surface waters led to the necessity of introducing some measures which would tend to repress, as far as possible, these saprophytic water organisms and which would also permit of the differentiation of the typhoid organism from the colon bacillus and other allied forms which might naturally be expected to be found in sewage.

10482 These sacs were then immersed in large galvanized iron cylinders, the top and bottom of which were covered with a removable wire screen. They were immersed at a distance ranging from 6 to 12 inches below the surface of the water. This was done for the purpose of placing the sacs under such conditions as would not permit of their being torn to pieces by the violent wave action which frequently obtained under the conditions of the experiment. These galvanized cylinders containing these sacs were immersed in the waters of the Illinois river immediately above the Averyville wagon bridge at such a point as would permit of their being exposed to the rapid current of the stream, but protected by the false work of this bridge, so as to permit their escaping rupture from contact from passing boats and floating objects of any sort. The galvanized iron receivers which held these sacs were padlocked by the collector carefully each day after removing the requisite sample. As an additional precaution to prevent any tampering with the experiment, the bridge tenders were engaged to watch the galvanized receivers to see that no acident befell them in any way. The samples of water taken from the interior of the sacs were re-
10483 moved from the same day by day, and a quantity of water ranging from 7 to 10 cubic centimeters being taken out for each sample before the sample was removed, the parchment sacs were thoroughly shaken so as to distribute the contents uniformly and thus permit the securing of a proper sample. The samples were removed in sterile containers, taken immediately to the laboratory and culture plates prepared in accordance with the plan previously outlined on the culture material, which was used by Prof. Jordan. The time which elapsed between the securing of the sample and preparation of the culture plates, ranged from one to not more than two hours.

10484 Recognizing the necessity of differentiating readily the typhoid organism, from the water bacteria, and sewage organisms which might possibly be present in the waters of the flowing stream, it was deemed preferable to make the cultures used for the isolation and separation of the presumptive typhoid organism upon media which would, if possible, inhibit the growth of these other than typhoid forms, or at least permit of the more or less ready differentiation of the typhoid bacteria from related organisms. For this purpose, Drigalski's medium was

employed for the differentiation of the typhoid organism. In order to eliminate any possible variation which might come from the use of different batches of such media, I received at my request from Prof. Jordan a batch of the above mentioned media and a part of which was also retained by him, for the purposes of use in the portions of the experiment, which was detailed to him. This permitted of the direct comparison of the organisms as to the numbers and kinds found in the waters of the Illinois river at Averyville in the comparison with the samples
10485 which were taken from the drainage canal by Prof. Jordan.

In making the cultures, wide variations in the amount of culture material was employed until such experience was acquired as would permit of the preparation of plates which would give the maximum amount of bacterial growth without causing a suppression of the organisms on account of their being present in such large numbers as to prevent the proper development of the cultures.

Culture plates were incubated at blood heat for a period of 24 hours. They were then examined and from the resultant growth which was obtained on the same, pure cultures were isolated on agar or glucose agar and prepared for shipment to Madison.

The plates were kept for a certain period of 24 hours at the room temperature in order to permit of the further development of any colonies which might not have appeared during the first 24 hours' incubation of the cultures at the higher temperature. They were then worked over again and in case any organisms were noted which resembled in any way the colonies of the typhoid fever organism, as indicated by their growth
10486 upon the Drigalski's medium, they were isolated, tubed, and also sent to Madison for further study.

Recognizing the fact that a considerable part of the variation in results which have heretofore been reported on the longevity of the typhoid fever organism when exposed in waters which normally contained water bacteria, is due to a variation in the amount of seeding which is present in a given volume of liquid, this series of experiments was extended by seeding duplicate sacs filled with river water, with a varying quantity of a freshly grown typhoid culture. In this series of experiments there were placed 15 different parchment sacs, inoculated with three different strains of freshly isolated typhoid organisms, denominated "X," "Y" and "Z," which had been previously received from Prof. E. L. Jordan .

Sacs 1, 2, 3, 4 and 5 were inoculated with that strain of organism designated as typhoid "X."

Sacs 6, 7, 8, 9 and 10 were inoculated with that strain of typhoid organism denominated typhoid "Y."

Sac No. 11 was a non-inoculated control sac, filled with water from the river.

10487 Sacs No. 12, 13, 14 and 15 were inoculated with strains of culture taken from a culture denominated typhoid "Z."

The amount of seeding of a typhoid organism placed in these sacs ranged in the case of the X cultures, from approximately 1000 typhoid organisms per cubic centimeter in sac 1, approximately 2000 typhoid organisms per cubic centimeter in sac 2, approximately 4000 typhoid organisms per cubic centimeter in sac 3, approximately 10,000 typhoid organisms per cubic centimeter in sac 4, and approximately 20,000 typhoid organisms per cubic centimeter in sac 5.

In the series of sacs inoculated with the culture "Y," the range in seeding was approximately the same: About 1000 typhoid organisms per cubic centimeter being inoculated in sac 6. Approximately 2000 in sac 7, approximately 4000 in sac 8, approximately 10,000 in sac 9, and approximately 20,000 in sac 10.

In the series of cultures, or, rather, in the series of sacs, infected with "Z" culture, sac 12 received 540 typhoid organisms per cubic centimeter. Sac 13 approximately the same
10488 number, sac 14, approximately 5400 typhoid organisms per cubic centimeter and sac 15 approximately 10,800 typhoid organisms per cubic centimeter. This gave a range from the lightest to the heaviest seeding represented in the series of cultures inoculated with "X," "Y" and "Z," from 1 to 20 fold. These seedings were determined by taking an equivalent amount of culture to that which was used in the seeding of the sac, and plating the same upon Drigalski's culture medium so as to determine with approximate accuracy the number of inoculated organisms. In conjunction with this inoculation the number of organisms which were normally present in the uninocu-

lated water was also determined, so as to show the relative number of typhoid bacteria, to those which normally belonged to the water.

These determinations of the water bacteria were also made at first upon Drigalski's medium which does inhibit the growth of a large portion of the water bacteria, but inasmuch as Drigalski's medium was used for the detection of the typhoid organism, it was regarded as essential to know the relative number of typhoid germs which were added to parchment sacs in
10489 comparison with forms normally present in the water.

The number of water bacteria found in each sample in a cubic centimeter of river water were approximately 50 to 80, whereas the number of typhoid organisms which were inoculated in such waters, which gave the strongest growth on Drigalski medium of water bacteria, ranged from the minimum of 540 per cc. to 20,000 per cc. The ratio then of typhoid fever organisms to all other organisms present in the water, was in the lowest case about 11 to 1, and in the strongest seeding about 40 to 1.

In this way, it is evident that the seeding of typhoid bacteria which was placed in the water, would be vastly greater than would be likely to obtain under natural conditions where typhoid material found its way into flowing streams.

For the purposes of comparison of the purity of this water with that of waters taken from any other sources, and particularly with the waters in Lake Michigan, the number of organisms per cubic centimeter as found in the water of the river, was determined upon ordinary nutrient agar as well as upon Drigalski medium.

The results of those analyses made on a number of days, are as follows:

10490 Oct. 13, river water, plain agar, 500 bacteria per cubic centimeter, Drigalski, 80.

Oct. 15, river water, plain agar, 60 bacteria per cubic centimeter, Drigalski, 25.

Oct. 16, river water, plain agar, 240 bacteria per cubic centimeter, Drigalski, 55.

Oct. 19, river water, plain agar, 200 bacteria per cubic centimeter, Drigalski, 40.

Oct. 21, river water, plain agar, 163 bacteria per cubic centimeter, Drigalski, 2.

Oct. 23, river water, plain agar, 102 bacteria per cubic centimeter, Drigalski, 11.

It is thus evident that the use of the Drigalski medium gave us exceptional conditions for the repression of the indigenous water bacteria, and rendered it possible for the easier detection of all typhoid colonies which developed on the medium.

This is a matter of importance, as it frequently happens in experiments of this sort that the number of indigenous organisms is so large in comparison with the adventive organisms, such as the typhoid germ, that the failure to detect the presence of the typhoid germ may easily arise from the overlook-
10491 ing of isolated colonies of this organism when grown in cultures containing large numbers of indigenous bacteri.

The cultures were shipped by express to Madison, where they were subjected to all of the differential tests which are necessary to differentiate the typhoid organism from related bacteria.

Cultures were first made in glucose agar. In this medium the typhoid organism is unable to ferment the sugar. The colon and other sewagic forms, are capable of producing gas.

By an inspection of the cultures frequently for 24, and always after 48 to 72 hours of incubation, it was possible to eliminate all cultures of the colon type by reason of their rapid fermentation of the glucose sugar.

All cultures which showed no signs of gas production, when inoculated in glucose shake cultures, were then inoculated upon nutrient gelatine, litmus milk, and glucose free broth for the production of indol.

Indol cultures were then incubated at blood heat for a period of 3 to 4 days; all milk cultures for not less than 7 days,
10492 and all gelatine cultures, were kept under continuous observation for a period of not less than ten days.

All cultures which showed no tendency to liquefy gelatine in ever so small a degree, or which caused the production of acid in litmus milk, with the decolorization of the litmus solution and the curdling of the milk, and all cultures which showed in litmus milk the production of alkaline reaction, evidenced by the increasing intensity of the color of the litmus solution, were excluded from further consideration.

All cultures which had shown no signs of gas in glucose shake cultures, no signs of liquefaction when grown for a period of not less than 10 days in nutrient 10 per cent. beef broth gelatine, and which were unchanged, or showed only a change to a lilac tint in milk, were still held for examination, as presumptive typhoid organisms, and further tested. Also those which showed a negative reaction for indol were still held for examination and subjected to a test upon litmus dextrose broth made from glucose free media, to which 1 per cent. of glucose sugar and litmus was added.

The results of this series of cultures were then charted,
10493 and all organisms which were practically unchanged on
milk, and which showed negative indol reaction, but which were able to ferment glucose producing acid, thereby changing the color reaction in litmus dextrose broth solution, were still kept for further examination.

These results were then charted in accordance with the well known plan of Fuller, so as to permit of the use of plus or minus signs for ready identification and all organisms which were aberrant, with reference to typhoid characteristics in only one characteristic, were again retested so as to be absolutely certain that the culture characteristics were correct. No organism was eliminated from this series of culture tests unless it departed from the usually expected culture characters given in connecton with descriptions of the typhoid bacillus.

Cultures which had up to this point shown characteristics which brought them within the pale of the culture characters which are found in the case of the bacillus typhosis, were then
subjected to what is known as the agglutinating test,
10494 which is regarded as the most crucial test which any pre-
sumptive typhoid organism can be subjected to.

The agglutinating test was made by using the blood of rabbits which had been previously immunized by repeated and frequent injections of freshly grown agar cultures of the strains of the typhoid bacillus which were used in these experiments for this purpose.

For this purpose rabbits were immunized, with the cultures previously denominated "X," "Y" and "Z," respectively.

The degree of immunization was continued with these cultures until a point was reached were the agglutinating property of the blood of these rabbits was able to cause a sedimentation of a freshly prepared homeogenous emulsion of a 24-hour old agar suspension of the homologous organism in dilution of not less than 1 to 1000.

This degree of dilution is sufficiently high so that any organism which would react positively to blood in this diluted solution, would be regarded, so far as this most crucial test
10495 is concerned, as positively typhoid.

Adjourned until 9:30 a. m., Friday, February 19th, 1904.

9:30 A. M., Friday, February 19, 1904.

10496 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. H. L. RUSSELL

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

10497 Q. Professor, go on and describe the experiment in full which you made at Peoria?

A. In addition to the tests which were made for the use of homologous sera in which the degree of dilution of 1 to 1,000 was reached, further experiments were made with the use of control sera. The purpose of using these control sera, which consisted of taking the blood of normal rabbits, was that in some cases it has been found that organisms are capable of agglutinating the blood of the rabbits when the degree of concentration is very strong.

For this purpose in these control experiments the concentration of the blood serum which was used was increased ten-fold over that which was employed with the homologous sera. That is to say all organisms which gave a positive reaction with the homologous sera in the degree of dilution of 1 to 1,000 were further tested with normal sera of rabbits in the degree of dilution of 1 to 100. In such cases a negative test for aggulutination must be regarded as confirmatory evidence that a positive test in the degree of 1 to 1,000 with homologous sera is indicative of the fact that the organism
10498 tested is a genuine typhoid bacillus.

In addition to these tests with control sera a large number of organisms which were up to this time regarded as negative typhoid on account of their aberrent culture characteristics on nutrient media of the different kinds employed were used for agglutination with the respective sera in the degree of dilution of 1 to 1,000. In such cases organisms should show no agglutination if they had no typhoid affinities.

Further, in addition to the cultures which were tested with the homologous sera, 1 to 1,000, controls tests were likewise made in which the organism was exposed in test tubes to which no blood serum was added.

In such cases the turbidity of the homogeneous suspension which was produced by the mixture of the agar growth with the salt solutions which were used as a menstrum for testing these control tests, should remain unimpaired.

The results of the tests which were made with these different sera will be reported later, in a summary of findings.

As stated before, the number of bacteria which were naturally present in the water of the Illinois River at Averyville was
relatively low when placed upon Drigalski media. The
10499 number of typhoid organisms which were added per cc. to
the water in the parchment sacs was invariably very much
larger than the number of bacteria which appeared upon the Drigalski media. In no case was this ratio of water bacteria to typhoid organisms less than 10 to 1, and in the parchment sacs containing the strongest seeding were as high as 400 to 1.

As a natural consequence of this relation of the number of colonies which appeared upon the culture plates when Drigalski medium was employed for isolation, the large majority showed upon an examination of such plates, characters which allied them to the typhoid bacillus. The use of the Drigalski medium cuts out by far the larger proportions of the water bacteria, even more so than it does the sewage bacteria, and in as such as the colon or sewage bacteria occurs only in limited numbers in the waters of the Illinois River at Averyville, it naturally followed that by far the larger proportion of the appearing colonies under these conditions would be typhoid in appearance. It was, therefore, unnecessary to remove all of
the colonies which appeared upon the plates in every in-
10500 stance. This, however, was done in a number of in-
stances, and it was shown that the selection of representative colonies from the large number of presumptive typhoid

colonies which appeared on the plate gave as positive results for the determination of the presence of typhoid as did the removal of the entire number of appearing colonies.

It should be borne in mind that the work of identifying the presumptive typhoid organisms which were removed from the culture plates at Peoria required the work of several weeks, as these cultures were shipped to Madison and then subcultured at this place, and finally agglutinating tests employed. It was, therefore, impossible, in any case for us to determine whether an organism was going to be proved to be typhoid or not until after a considerable lapse of time, and this in no case was done until after the completion of the experiment at Peoria, so that it was impossible in any way for us to know the actual outcome of these experiments until after the experiment itself had long been completed.

The results of the findings as to the presence and absence of the typhoid organism in the respective parchment sacs which were placed in the water at Averyville will now be given.

10501 The series of cultures which were used in these experiments embraced three different strains, designated as "X," "Y" and "Z." In the series of the cultures made with the organism "X," five different sacs were employed, which were placed in the river on the 8th day of October, 1903.

In the series made with "Y," four were employed; in the series made with "Z" four.

The variation in the amount of seeding ranged from 540 typhoid organisms per cc. to 20,000. The results of the findings of those tests in the case of parchment sac number 1 are as follows:

From the plates made 24 hours after the sacs had been immersed in the water 12 colonies were removed, 1 of which was found to be typhoid.

On the third day 9 were removed, none of which proved to be typhoid.

On the fifth day 11 were removed, none of which were found to be typhoid.

On the tenth day 10 were removed, none of which were found to be typhoid.

In these different series emphasis was placed in the matter of tracing out the two extremes as far as seeding was
10502 concerned, therefore a large number of cultures were

taken of the sacs which contained the lightest and the heaviest seedings, and the intermediate seedings were used as checks or duplicates.

In the sac designated 2, inoculated with the "X" colony, 8 colonies were removed from the plates made on the 4th day. None of these was found to be typhoid.

In sac 3, 12 colonies were taken off on the sixth day, none of which was found to be typhoid.

In sac number 4, 13 (13) colonies were removed, on the 4th day, none of which was typhoid.

On the 5th day 3 colonies were fished. None of these proved to be typhoid.

On the 7th day 8 were removed, none of which was typhoid.

In sac number 5, "X" series which contained the maximum degree of seeding, 20,000 typhoid organisms per cc. the total approximate typhoid contents of the tube being about 4,000,000 typhoid bacteria in the 200 cc. sample used.

6 colonies were taken off the plates made on the first day,
10503 none of which was found to be typhoid.

13 were removed on the second day, two of which were found to be typhoid.

9 were taken off on the 5th day, none of which was typhoid.

8 were taken off on the 6th day, none of which was typhoid.

7 were taken off on the 7th day, none of which was typhoid.

12 were taken off on the 10th day, none of which was typhoid.

12 were taken off on the twelfth day, none of which was typhoid.

11 were taken off on the 14th day, none of which was typhoid.

15 were taken off on the 17th day, none of which was typhoid.

Sacs numbered from 6 to 10, inclusive, inoculated with the "Y" culture were placed in the river on the 10th day of October, 1903. The results of the findings with cultures taken from these sacs are as follows:

10504 Of 8 colonies which were removed from the plates after the organisms had been exposed in the sac in the river water for one day, 3 colonies proved to be typhoid.

Of six removed on the third day 2 proved to be typhoid.

In these particular sacs no further tests happened to be made until the 14th day on which 9 were removed, none of which was typhoid.

In sac 7, 9 colonies were removed on the 4th day, none of which proved to be typhoid.

5 were removed on the 12th day, none of which was typhoid.

5 were removed on the 14th day, none of which was typhoid.

6 were removed on the 16th day, none of which was typhoid.

In sac 8, 8 were taken on the sixth day, none of which was typhoid.

6 were removed on the tenth day, none of which was typhoid.

4 were removed on the 12th day, none of which was typhoid.

10505 8 were removed on the 16th day, none of which was typhoid.

In sac 9, 11 were removed on the 4th day, none of which was typhoid.

7 were removed on the 7th day, none of which was typhoid.

11 were removed on the 10th day, none of which was typhoid.

6 were removed on the 12th day, none of which was typhoid.

In sac number 10, containing the highest amount of seeding 20,000 typhoid organisms per cc., 8 colonies were taken on the first day, 4 of which proved to be typhoid.

16 were taken on the 3rd day, 10 of which proved to be typhoid.

18 were taken on the 5th day, none of which was typhoid.

6 were taken on the 7th day, none of which was typhoid.

7 were taken on the 10th day, none of which was typhoid.

Tube number 11 was used as a control tube, filled with 10506 river water, but not seeded with the typhoid organism.

Cultures were made of this from time to time but no presumptive typhoid colonies were observed.

Series consisting of sacs 12 to 15, inclusive, inoculated with the "Z" culture, and immersed in the river on the 15th day of October, 1903, were found to show the following results:

Tube Number 12, inoculated with 540 typhoid organisms per cc., the lightest seeding which was employed in the case of any of the experiments, showed, 1 hour after the tube had been immersed in the water, 3 positive typhoid colonies out of the 3 colonies which were removed.

After 24 hours immersion in the water 17 colonies were picked off from the colonies of which 15 were found to be typhoid.

On the second day 12 were taken off, 6 of which were found to be typhoid.

On the 5th day 18 colonies were removed, none of which were found to be typhoid.

On the twelfth day 2 colonies were taken off neither of which was typhoid.

Sac 13 showed on the 7th day no typhoid colony of the
10507 3 which were removed.

On the ninth day 4 colonies were fished off, none of which proved to be typhoid.

7 colonies were removed on the 12th day, none of which was typhoid.

Sac 14 one hour after immersion, 3 colonies were removed, all 3 proved to be genuine typhoid.

7th day, 1 colony taken off found not to be typhoid.

Sac 15 24 hours after immersion 15 colonies were removed, 14 of which proved to be typhoid.

On the second day 13 colonies were taken off, 6 proved to be typhoid.

On the 5th day 12 colonies were removed, none of which proved to be typhoid.

On the 9th day 14 colonies were removed, 1 of which proved to be typhoid.

On the 12th day 2 colonies were removed neither of which proved to be typhoid.

Summarizing the results obtained in the foregoing analyses 72 colonies were examined from the different sacs after they had been exposed in the water for 24 hours and of these 43
were found to be typhoid. These 72 colonies were taken
10508 from 8 different sacs, and in these 8 sacs the typhoid
organisms were found in 7 of these sacs.

Of the 25 colonies which were examined on the second day, 12 were found to be typhoid.

These 25 colonies were removed from 2 sacs, both of which contained typhoid.

Of the 44 colonies removed on the third day 14 of them were found to be typhoid.

These 44 colonies were taken from 5 sacs and the typhoid organisms was found in three out of five of these sacs.

41 colonies were taken off on the 4th day, from 4 different sacs, and in none was any typhoid colonies found.

61 colonies were removed on the 5th day from 6 different sacs and in no case was typhoid found.

28 colonies were taken from 3 sacs on the 6th day, and none proved to be typhoid.

32 colonies were taken from 6 sacs on the 7th day, none of which was typhoid.

18 colonies were taken from 2 sacs on the 9th day, 1 of which proved to be typhoid.

10509 On the 10th day 5 sacs were examined, 46 colonies being removed, no typhoid found.

In 7 sacs taken on the 12th day, 38 colonies were examined, none were found typhoid.

In 3 sacs examined on the 14th day, 25 colonies were removed, none were typhoid.

From 2 sacs examined on the 16th day 14 colonies were removed, none of which were typhoid, and in 1 sac examined on the 17th day 15 colonies were taken off, none of which were typhoid.

In these particular series of experiments 459 colonies were examined. The different sacs which were employed were tested 54 times and the typhoid organism was found fourteen times, 70 colonies out of the total 459 belonging to this organism.

During the first 3 days 141 colonies were fished off, 69 of these were found to be typhoid and in the 318 cases which were examined after 3 days only 1 typhoid organism was found.

Q. Have you prepared a table of summaries, based upon this experiment with the typhoid bacilli in the parchment sacs?

A. I have.

10510 Q. Will you produce and read such table of summaries?

A. It is as follows:

10512 **Q. Did you make any other experiment, using any other means except the parchment sacs?**

A. Yes sir.

Q. Will you detail the experiments that you made wherein you employed other means, in full?

A. In addition to the series which were made with the parchment sacs, another method was used which approached the problem from a somewhat different point of view. The method which was employed in this case was as follows:

Ordinary commercial agar which is a plant jelly ordinarily employed for bacterial purposes was taken and this was washed in running water for a period of several days so as to remove as far as possible, all soluble products which might happen to be present in this agar substance. This agar was then prepared in the usual manner followed in bacteriological laboratories when such is employed in the preparation of nutrient media and from the prepared agar small rectangular blocks were cut out, which were about a half inch square, and about 2 inches long. These rectangular blocks were inoculated with
10513 freshly grown typhoid cultures by means of a platinum wire. This forced the typhoid organism down into the center of the block; and the top of these agar blocks was sealed from contamination with the exterior by means of searing the surface with a hot iron. The typhoid organism under these conditions was placed in a medium which was incapable of supporting growth as this ordinary agar had had added to it no nutrient substances, and moreover all soluble substances capable of being removed by soaking were taken out. Tests were made upon this non-nutrient agar to see whether the typhoid organism would be able to grow under these adverse conditions. It was found that such was not the case. According to Oswald the eminent German physicist, this soluble agar possesses the property of allowing diffusion to take place quite as rapidly through its substance, as would be the case in water itself. Hence it follows that if typhoid organisms were placed on the interior of an agar mass and then exposed in an aqueous medium containing bacteria of various kinds then the typhoid organism would be subjected to the influences which would arise
10514 from the growth and development of these water or sew-

age bacteria in the surrounding media in which these agar blocks were immersed.

Control experiments were instituted when these agar blocks inoculated with the typhoid bacilli were not exposed in water but kept in air. It was determined, under these conditions, that the typhoid organism was not capable of growing in these blocks, but was capable of retaining its vitality for a period of time which was at least two weeks and in some instances considerably longer.

These agar blocks were inoculated with the three strains of typhoid bacilli, "X", "Y" and "Z", and were placed in considerable numbers in the waters of the Illinois River in small galvanized iron cylinders, the top and bottom of which were covered with a coarse wire mesh. Under these conditions the water had free access to these individual blocks on the inside of which were inoculated these pure cultures of the typhoid organism. The results of the series of tests, 4 in number, which were made with cultures "X," "Y" and "Z," are as follows:

Series 1, inoculated with culture X, was examined on the first day by taking one of these agar blocks from the number which was immersed and paring off the upper surface of
10515 the block and attempting to transfer any material which
was in the line of the inoculation previously made.

It should be said in this connection that the exact point where the typhoid organism was present was known because in making this inoculation the needle was first touched to a mass of sterilized carbon, and then touched to the typhoid culture so that in making the inoculation a streak of black carbon was deposited along the line of the needle track, together with the typhoid organisms which of course would be transferred. In this way the exact location of the typhoid germ could be determnied in every case and in removing the transfer cultures care was always taken to see that the needle traversed the sooty streak which marked the place where the typhoid organisms had been planted. Transfers made from this first series of agar blocks were made on the first, third, fifth, ninth, twelfth, fourteenth, sixteenth and nineteenth days, after their immersion in the river water. In no case did any resultant growth occur in any of the sub-cultures which were made from these
10516 transfers.

Series 2 was inoculated with the same organism and cultures taken immediately, on the first, second, third, sixth, eighth, tenth and thirteenth days and typhoid organisms found in the case of the transfers which were made immediately after the infection, also on the second day.

Series 3, inoculated with the strain of typhoid organisms designated as "Y," were prepared in a similar way and from these cultures transfers were made immediately after inoculation, on the first, third, fifth, seventh, tenth, twelfth, fourteenth and seventeenth days. In no case was any organism found in such transfers except those which were found in the transfers made immediately after insertion, and also on the fifth day.

In the fourth series, inoculated with "Z" culture, cultures were removed immediately after inoculation on the 1st, 2nd, 3rd, 6th, 8th, 10th and 13th days. In this series organisms belonging to the typhoid class were found in those transfers made
10517 immediately after inoculation on the 1st, but at no later date.

These experiments were conducted in the river water of the Illinois River at Peoria. Subsequent to this time another series was made in the lake water of Lake Mendota, at Madison, Wisconsin, in order to increase the amount of data long this line and to determine any possible variation in waters of different organisms. These consisted of two experiments made in a similar manner with non-nutrient agar, and cultures were removed on the 3rd, 7th, 11th, 12th, 15th and 21st days after their immersion in the water. From these sub-cultures were prepared and in no case was the typhoid fever organism found except in the case of the samples removed on the third and seventh days.

A second series was also prepared in which cultures were removed on the 3rd, 7th, 10th, 12th and 15th days, and in no instance was the typhoid organism found, except in the case of the colony removed upon the third day.

The summary of the results of these cultures on the vitality of the typhoid fever organisms, inoculated in numbers, so large that the number of organisms produced turbidity to be
10518 recognizable with the unaided eye, that the exposure of these numerous typhoid organisms in the waters of the

Illinois River and also in the waters of Lake Mendota at Madison, resulted in loss of vitality of this enormous number of typhoid bacteria to such an extent that in no case were any typhoid organisms found after the eighth day and in the case of one series none was found even on the first day. This variation in the vitality of the typhoid cultures, were an indefinite number of organisms were inoculated, under these conditions, and where it was not exposed directly to the competition which exist between water and sewage bacteria and the typhoid organism is more surprising as the organism was not directly exposed to the influences of the competing bacteria themselves but merely to the soluble products which these germs are capable of producing.

Q. Professor, how did the experiment with the agar block differ from the experiment with the parchment sacs?

A. In the case of the parchment sacs the typhoid bacteria were exposed to the direct contact of all of the water or other bacteria which might be present in the samples of water which were placed in the sacs. In the case of the agar blocks 10519 the typhoid organisms were not exposed to this direct contract but were exposed to those products of the metobolic activity of water and other bacteria which might be present in the outside medium and which would find it possible, if in solution, to pass through the agar block, by diffusion, and so possibly act upon the typhoid bacteria themselves which were screened by these agar blocks.

Q. Which method afforded the best opportunity for the life of the typhoid, the agar block or the parchment sacs?

A. I find that the experiment made with the agar blocks gives more favorable conditions for the retention of the vitality of the typhoid organism than was the case in the parchment sacs where the contact of typhoid organisms with other bacteria was rendered possible.

Q. Are you acquainted with the results of that part of this experiment which was made by Professor Jordan on the waters of the drainage canal and Professor Zeit on the waters of the Chicago River and Lake Michigan?

A. Since the practical completion of the experimental work which was done at Peoria, I have had several conferences with

Professors Jordan and Ziet relative to the experiments
10520 which were assigned to them, and am familiar with the
results which they have obtained in these experiments on the longevity of the typhoid organism in the waters of Lake Michigan, the Chicago River and the drainage canal.

Q. From the results obtained in this combined experiment what conclusion do you draw as to the longevity of a typhoid bacillus in the water of Lake Michigan?

Mr. Jeffries: I object to that for the reason there is not a sufficient number of examinations made upon which to base a safe and reliable opinion.

A. I should say from the results of these experiments with which I am familiar, that the longevity of the typhoid organism immersed in the waters of Lake Michigan would be considerably longer than in the waters of the Chicago River, and the organism would probably be able to live for a period of six or eight days.

Q. What conclusion do you draw as to the longevity of the typhoid bacillus in the waters of the Chicago River and the drainage canal, based upon the results of this experiment, conducted by Professors Zeit, Jordan and yourself?

10521 Mr. Jeffries: Let the record show that the complainant
objects to the witness giving any opinion upon any of the determinations made in this joint and concurrent experimental transaction for the same reasons stated in the objection to the previous question.

A. I should consider that the typhoid organisms deposited in the waters of the Chicago River and drainage canal would have a much shorter duration of vitality than in waters of Lake Michigan, and that such vitality would not extend to a period of more than two or three days.

Q. What conclusion do you draw as to the longevity of a typhoid bacillus in the waters of the Illinois River, based upon this experiment?

A. From experiments which I have actually made when freshly isolated cultures of bacillus typhosus were exposed in permeable sacs in varying numbers so that the germ content of the typhoid organism exceeded at least the germ content of the water used in the ratio of 100 to 1 or more, and where the or-

ganisms were destroyed in the course of about three days, with
one possible exception, and that if this was the condition which
was obtained under the conditions in which the experi-
10522 ment was made, when the effect of other environmental
factors were excluded, such as the influence which would
come from sedimentation, dilution, influence of light, vital concurrence with green plant forms which might be found in the waters of such river, I should certainly consider that the life of the typhoid organisms when subjected to the more severe conditions which obtain in the waters of the Illinois River itself than was the case in the experiments with the parchment sacs, that it certainly would be no longer in the waters of the Illinois River and in all probability would be shorter, hence I would conclude from the foregoing data that the vitality of the typhoid organism would not in any case be maintained for more than a period of a very few days, three or four at the outside.

Mr. Jeffries: I move to strike out the answer for the reason that it is not entirely responsive to the question in that it is not based upon the statement of facts contained in the question, not confined to the experiments made by this witness and the experiments made by Professor Jordan and Professor Zeit, jointly, but that the witness has taken into consideration other factors such as sedimentation, dilution and plant destruction of bacteria, and I move to strike out all the testimony of this
witness and Professors Jordan and Zeit with reference to
10523 these particular experiments, for the reason that from the
answer given by this witness other things must be taken
into consideration in determining the life of the typhoid beside the naked experiments themselves, and that any conclusions or opinions that may be based upon these experiments alone as to the life of the typhoid germ are unreliable and untrustworthy as shown by the testimony of this witness in the answer which he has just given to the last question.

Q. What in your opinion, based upon all the knowledge which you possess in regard to typhoid germs would be the fate of the typhoid bacillus passing from the sewers of Chicago into the Chicago River, and thence into the drainage canal, and down the Desplaines and the Illinois Rivers?

A. In view of the facts that have been obtained in the

experiments which have been conducted conjointly by Professors Jordan, Zeit and myself, and in view of my knowledge of the conditions which would obtain where the sewage of Chicago was allowed to flow in to the Chicago River, thence into the drainage canal and down the Desplaines and Illinois Rivers, and in view of the fact that the experimental evidence as to the vitality of the typhoid organism when exposed to the waters as
10524 found in the Chicago River, the drainage canal and the Illinois River, under the conditions of the experiment previously described, and in view of the fact that in my judgment typhoid organisms so deposited in the Chicago River, drainage canal and the Illinois Rivers would be subjected to even more detrimental conditions than did exist under the conditions as recorded in these experiments, and in view of the fact that the sewage of Chicago, deposited in the Chicago River and finding its way through the drainage canal, and down the Desplaines and Illinois Rivers would require a much longer period of time to pass from the city of Chicago down the Desplaines and Illinois River than is required to kill typhoid organisms when placed in such an environment as would exist under these conditions.

I am of the opinion that typhoid organisms finding their way through the sewers of Chicago, into the Chicago River and thence into the drainage canal, down the Desplaines and into the Illinois River would be destroyed before such water had passed the course of the Illinois River.

Q. From a scientific standpoint what value do you attach
10525 to this experiment as showing the longevity of a typhoid bacillus in polluted waters?

A. In comparing numerous experiments which were made under varying conditions as to the longevity of the typhoid organism in the waters of the drainage canal and the Illinois River with the experiments which have been previously reported by other investigators on the typhoid organisms exposed under various conditions, I am of the opinion that the conditions under which the experiments now reported were made approach more nearly to the natural conditions to which the typhoid fever organism would be subjected when exposed in the water of the flowing stream such as would be the case in the Illinois

River in passing from the city of Chicago down the said river, and therefore from a scientific standpoint a greater value is to be attached to the important results of this experiment made by Professor Jordan, Zeit and myself, independently but concurrently, than to the conclusions which have been previously drawn from the experiments of other investigators, and that the results of such experiments show that the longevity of the typhoid bacillus is less in polluted waters than in waters of a pure class.

Q. Does this experiment shed any light upon the longevity of the typhoid bacillus in the sediment of polluted 10526 streams?

A. Pathogenic bacteria exposed in the sediment of polluted streams are brought in contact with even a larger number of bacterial organisms than would be the case if they were exposed to superincumbent water masses and therefore presumably in contact with the increasing amounts of metabolic products, and inasmuch as the pore spaces between the particles of sediment are entirely filled with water, it is my opinion that the conditions which would obtain in the sediment of polluted streams would certainly not be less prejudicial than those which would be found in the water of the stream itself, and therefore I would consider that if the longevity of the typhoid bacillus be impaired by the action of sewage and the water bacteria of a polluted stream that at least the same if not a greater effect would be produced if the typhoid organism was in contact with these bacteria and the products of their growth in the sediment of such a stream.

Q. Had this experiment been conducted in warm weather instead of the season that it was, what effect in your opinion would be manifested in the results?

A. It is a well recognized fact in bacteriology that the 10527 vitality of various organisms, particularly those of a pathogenic class which find unsuitable conditions for their development in the outside environment is profoundly affected by temperature of their surroundings, and the results of many tests upon this point indicate that the vitality of such organisms is retained for a longer period of time during those periods when the temperature is low than is the case when higher temperature prevails.

The reason for this undoubtedly lies in the fact that the characteristic changes which occur in the life history of any organism go on more rapidly with an acceleration in temperature, and therefore if this experiment had been conducted at those seasons of the year when the metabolism of all organisms is at its highest during the period of highest temperature the results of the experiments undoubtedly would have shown that the vitality of the organisms would not have been as long as was the case when the temperature under which the experiments were conducted was materially lower than those which would have prevailed in the height of summer.

Q. What is the behavior of colon bacillus in soil as compared with its behavior in water?

A. The colon bacillus in ordinary soil which is not satu-
10528 rated completely with water is able to live longer than it
is in the water itself.

Q. Is there such a thing as purification of soil?

A. Dead effete organic matter undergoes slow decomposition which universally results in the disintegration of such matter and consequently purification of the soil from such refuse material. Such beneficient operation prevents the surface of the earth from being clogged with the accumulated mass of organic debris and refuse which would result from the death of living forms and which would render continued residence on its surface possible. Inasmuch as we know that this does not occur, it is therefore evident that organic matter discharged on the surface of soil or in soil does undergo a series of changes which result in its destruction and consequently the purification of such soil.

Q. Why is it that the typhoid bacillus will not live as long in polluted water as in pure water?

A. Polluted water is likely to contain a large amount of or-
ganic matter which encourages the rapid growth of sew-
10529 age and other saprophytic bacteria which may find their
way into it, and these bacteria in their growth are capable of producing various compounds or products which I have previously testified to, on the basis of experimental results, as exerting a positive deterimental effect upon other forms of bacterial life. This prejudicial effect is likely to be more marked

upon bacteria belonging to the pathogenic class and which have therefore not habituated themselves to an environment suitable to saprophytic development.

Inasmuch as these conclusions are based upon experimental results which have been previously reported, in my opinion it therefore follows that the typhoid organism would not live as long in waters which were rich in germ life or the products of germ activity, as would be the case in pure water in which these bacteria or their products were not present.

Q. To what do you attribute the death of the typhoid bacillus in water?

A. The typhoid fever organism naturally thrives upon complex organic material and inasmuch as it does not ordinarily find suitable food supply in normal waters which permit
10530 the active cell growth, the starvation of typhoid cells when placed in water must soon set in, and it is a question therefore as to how long such organisms will be able to preserve their vitality in such a medium. The death of an organism of this class is undoubtedly due to the operation of a complex series of conditions.

It is a well known fact that direct sunlight exerts a detrimental effect upon bacteria with which it comes in contact. Particularily is this true in relation to the organisms belonging to the pathogenic class. An exposure of the organisms, such as the typhoid, to the direct rays of the sun will destroy the vitality of these organisms in a short period of time. It has also been demonstrated that another powerful factor which is operative in the destruction of the typhoid organism is that which comes from the effect in which various water and sewage bacteria or the bi-products of which they are capable of exerting have upon the vitality of the typhoid bacillus. When the typhoid organism is brought in contact with large numbers of these organisms it has been demonstrated that it is unable to retain its vitality for more than a brief period of time. In addition to this there should be mentioned the effect which comes from further
10531 competition which may exist between other forms of life which may be present in the waters in which the typhoid organism is exposed, including under this head the microscopic forms of life, both animal and vegetable, such as algae and other

related organisms. The effect of sedimentation in waters more or less heavily charged with suspended material; the effect which comes from the addition of varying quantities of water not containing these organisms in varying numbers has a tendency to place the typhoid organisms in such waters under conditions where this rate of starvation or actual destruction which takes place through the effect of these varying forces will go on. These factors are undoubtedly the main ones which appeared to cause the more or less rapid loss of the vitality of the typhoid organism when exposed in a watery medium.

Q. Will the typhoid germ live as long in the waters of the Illinois River as in the waters of Lake Michigan?

A. I do not think that the typhoid organism would live as long in the waters of the Illinois River under the conditions as there exist in nature as would be the case in the waters of Lake Michigan.

10532 Q. How do you explain the more rapid death of the organism in the waters of the Illinois River than in the waters of Lake Michigan?

A. The waters which are found in the Illinois River are derived from the smaller tributaries to which is added the waters brought from Lake Michigan through the Chicago River and drainage canal. The waters coming from Lake Michigan through the Chicago River and drainage canal receives a very large amount of bacterial life, largely of a saprophytic class, which find it possible to grow and multiply to an enormous extent in these waters. The result is that these organisms are capable of producing various products of growth, some of which are unquestionably soluble as is shown from the results of the previous experiments recorded and these soluble products find their way down the waters of the drainage canal, Desplaines River and into the Illinois River after the organisms which have produced them may have disappeared. The result is that even after the process of self purification has gone on to such an extent as to reduce the germ content from the high numbers
10533 which exist in the drainage canal to the low germcontent which is found at certain points in the Illinois River that the soluble product which have been made by these organisms in the upper reaches of the river pass from the same as would

be the case of any material in solution. It is therefore conceivable that products of this class are present in the waters of the Illinois River in the same way for instance as is chlorine which has been derived from the sewage of Chicago and the presence of which is detected in the waters of the Illinois River even after the organisms which were present in the sewage and therefore in contact with the chlorine of that sewage have entirely disappeared. The presence of these soluble substances has been demonstrated in experiments previously reported, but further proof can be adduced in the experiments which have not yet been detailed, and which were conducted in the following manner:

Cultures were taken and prepared with various saprophytic bacteria planted in agar. These organisms were allowed to grow for a period of 24 hours and then over the surface of these agar plates was streaked cultures from freshly grown subcultures of the typhoid bacillus. A portion of these plates was left free from the growth of the water and saprophytic
10534 bacteria so as to serve as a control which would be indicated by the growth of the typhoid bacillus. In these plates, half of which were seeded with various saprophytic bacteria and half of which were free from any growth of these organisms, the typhoid organism was seeded by drawing an infected wire over the surface of such plates. It was observed that when the needle infected with the typhoid organism was drawn over the sterile agar surface abundant growth occurred, but where the needle was traced over the surface of the plate on which these other organisms were beginning to develop that the typhoid organism was incapable of thriving to any material extent. If the two infections, that is the infection of the plate with the water bacteria and the typhoid organism were made simultaneously, the typhoid organism was able to make a small growth. In case where the water bacteria were inoculated first and the typhoid organism later inoculated say 12 to 24 hours, the growth of the typhoid germ was usually absent. This indicates, in my judgment, that there are products produced by various bacteria indigenous to water and of a saprophytic class, some of which were isolated and found to be representative, common, well recognized water organisms, that this antagonism

between the products of the growth of these saprophytic
10535 bacteria and the typhoid germ are such as prevent the
growth and development of this organism inasmuch as this could only be produced through the action which is caused by soluble products diffusing through the agar medium, and it would indicate that the presence of colonies of bacterial growth would exert a poisonous or an inhibitive effect upon the development of the typhoid organism.

Q. What is your opinion as to whether the typhoid bacillus will live longer in the sediment of a polluted stream than it would in the water of the same stream?

A. If the typhoid organism is imbedded in the sediment of a polluted stream it would be surrounded entirely by a water medium in which there would be present a very large number of bacteria belonging to the saprophytic and probably the sewage class, a number which would ordinarily be much larger than found in the water above. Doubtless the amount of by products thrown off by the activity of these organisms, under the circumstances where these large numbers of bacteria would be found, would also be larger than would exist in the waters of the stream itself, taking into consideration the effect which the proceeding experiments have revealed as to the prejudicial
action of waters rich in bacterial life on the vitality of
10536 the typhoid organism in such waters it can hardly be
considered that the vitality of the organism in the sediment of such a stream would be enhanced; even there are germs in the water itself, and there is no evidence which I know of that indicates that the typhoid organism would be capable of living in the sediment of such a polluted stream for a longer time than it would in the water of the same stream.

Q. Will you differentiate between conditions that obtain in moist soil and the sediment of running streams?

A. The conditions which obtain in moist soil and the sediment of running streams are materially different. In the one case the soil is not completely saturated with water for the soil particles are surrounded by a hygroscopic film which adheres to the particles themselves, but gives a considerable amount of pore space in the interstices which is filled with air. In the sediment found in running streams or lakes this condition would not obtain as these spaces are entirely filled with water.

Q. Does the time that a typhoid bacillus will live in moist soil furnish any criteria for its longevity in the sediment of a running stream?

A. In as much as the conditions which would prevail in a moist soil where the soil interstices were largely filled 10537 with air, and where the amount of water present in such interstices was confined to the thin hyproscopic film which is in contact with the surface of the soil grain itself, and in as much as the conditions herein described are materially different from those which obtain in the sediment found in a running stream, it is my opinion that the conditions which obtain in a moist soil and the results which are here found would not furnish any criteria for the determination of the longevity of the organism as found in the sediment of a running stream.

Q. Are the two conditions comparable?

A. The two conditions as found in a moist soil and in the sediment of a running stream, for the foregoing reasons, are not comparable.

Q. Would the fact that a typhoid bacillus lived several months in moist soil, justify the assumption that it would live for the same length of time in the sediment of a river?

A. In view of the fact that the conditions under which typhoid organisms would be exposed in moist soil are different from those which are found in the sediment of a river, I would not consider that this would justify the assumption that it would live as long in the sediment of a river as would be the case if the exposure was made in moist soil.

10538 Q. Will you give the reasons for the answer you have just given?

A. The reasons which I would assign for the above answer rest upon the fact that the water content of the moist soils is confined to an exceedingly thin film surrounding the moist grain and that the large portion of the pore space between the soil particles is filled with air. These conditions do not obtain in the sediment of streams, .and inasmuch as a prominent factor in the destruction of typhoid bacteria is that which comes from the effect produced by the sewage and water bacteria on the products formed by that growth and inasmuch as the effect of this influence would be much less in the case of a moist soil than it would be in the case where the space between the soil particles was entirely filled with a watery medium, such as would be the case in the sediment in the bottom of a stream, I would not consider that the typhoid organism would be able to live as long in such sediment as would be the case in moist soil.

Q. Do you know of any bacteriologist since the birth of becteriology that has demonstrated by any experiment that typhoid germs do live in the sediment of lakes or rivers for a long period of time?

10539 A. The only experiment which I know of in which the claim is advanced that typhoid fever organism is capable of living for a long time in the sediment of lakes and rivers are those which were made by Lortet of Lyons, France, which were presented to the Tenth International Medical Congress at Berlin, in August, 1890, and published in the Centralblatt fur Bakteriologie, 1891, volume 9, page 709.

Q. From the experiment which you have introduced in evidence as well as the laboratory experiments which you have also introduced in evidence, what is your opinion as a bacteriologist as to the longevity of the typhoid bacillus in the sediment of the Illinois river?

A. On the basis of the experiments which I have been able to perform on the vitality of the typhoid organism when exposed to the waters of the Illinois river, and in view of the facts that the conditions which obtain in the bottom of that stream are such as would undoubtedly bring the typhoid organism in contact with even large numbers of water and sewage bacteria, and the products of their growth, that would often be the case in the waters of the stream itself, it is my opinion 10540 that the longevity of the typhoid organism when exposed in the sediment, as found in the Illinois river, would certainly be no longer than it would in the superincumbent water above, and that it is quite possible that their longevity might even be shortened.

Q. What conclusion do you draw from the experiment which you have introduced?

A. From all of the experiments which I have made on the conditions which obtain where the typhoid organism is exposed in the Illinois river it is my belief that this organism will lose its vitality in the conditions whch would obtain n the waters and in the sediment of such a stream in a relatively short period of time, that period of time not exceeding more than three or four days.

Q. Does the experiment which you have introduced shed any light upon the longevity of the typhoid bacillus in sewage polluted waters?

A. The experiments which I have conducted myself on the longevity of the typhoid organism in the waters of the Illinois river which are known to have received large quantities of sewage pollution, and when compared with similar experiments made by Professor Zeit in the waters of Lake Michigan,
10541 indicate that the longevity of the typhoid organism in such waters is considerably less than it is in the case of pure waters, and from the knowledge which I possess as to the results which have been obtained in the co-operative experiments previously mentioned, the special portion of which has been carried out by Professor Jordan and Professor Zeit, on the conditions which are found as to the longevity of the typhoid organism in the Chicago river and Drainage Canal, I am of the opinion that these experiments, taking them all into consideration, do throw, upon the question as to the longevity of the typhoid bacillus in sewage polluted waters, much light.

Q. Mr. Fuller, in his testimony on page 4218, stated that there are observers in Switzerland who made examinations with positive results, showing the presence of typhoid germs in the sediment of Lake Geneva, and I think also Lake Zurich. Do you know anything about those observations to which Mr. Fuller referred?

A. I do.

Q. What were the facts and circumstances in connection with these observations?

10542 A. These observations which are referred to by Mr. Fuller are, I take it, those which are reported as made by Mr. Lortet, of Lyons, France, and were peresented to the International Medical Congress at Berlin, and published in the journal referred to above.

. It was stated in this paper that samples of the sediment were taken from Lake Geneva, at a distance of a mile and a quarter from shore, and at the depth of 120 to 150 feet, where the temperature of the water was approximately 40 degrees Fahrenheit. It is further stated that the water over the places where these organisms were removed was a chemically pure water. It is further stated that an analysis of the samples of mud taken under these conditions revealed the germs of tetanus or lock jaw, typhoid fever and possibly the tubercular organism.

It is further stated in this paper that other samples were taken from a point 200 meters from shore, and in water 12 feet deep, and that the mud under these conditions was found to be absolutely sterile.

It is further stated that it was commonly observed that when
portions of this lake sediment were injected into labora-
10543 tory animals that it resulted in the production of malig-
nant oedema, and the opinion is advanced that there
may have been an actual multiplication of these disease producing bacteria in this mud for many generations.

Adjourned to 2:00 p. m., February 19, 1904.

10544 Met pursuant to adjournment at 2 p. m., February 19th, 1904.

Present, the Commissioner and same counsel.

PROF. H. L. RUSSELL

resumed the stand for further direct examination by Mr. Todd and testified as follows:

Q. In the light of the present knowledge in regard to bacteriology what importance do you attach to those observations?

A. From the results of the experiments which have been quoted it is my belief that these experiments were either carelessly performed or not carried out with sufficient detail, and under sufficiently stringent precautions to warrant the conclusion which is drawn. The reasons for my belief as indicated are as follows:

It is stated in this paper that samples were taken a mile and a quarter from shore at a depth of 120 to 150 feet, and at a temperature of 40 degrees Fahrenheit and that the water over

these samples was a chemically pure water, and that in
10545 the mud found underneath this chemically pure water
the germs of tetanus typhoid and possibly tuberculosis
were present.

If the sediment in the bottom of this lake contained the pathogenic organisms referred to it would be probable that there would be some evidence of the organic pollution which would have resulted in the deposition of such organism say as typhoid fever. Moreover, he further states that in samples taken 200 metres from shore and in water 12 feet deep the mud was found to be perfectly sterile, a condition which is known and recognized by all bacteriologists of repute to be totally at variance with the actual facts of the case. There is no reference made in these experiments to the length of time which it is supposed that these typhoid, tetanus and tuberculosis organisms had presumably been exposed in the mud of this lake.

The details which are given with reference to the identification of these organisms are exceedingly vague and indefinite.
No bacteriologist who makes the statement that tetanus,
10546 typhoid and possibly tuberculosis organisms are found
under any conditions, can help laying himself open to
the charge of careless manipulation because of the laxity of such statements.

In view of the fact that the majority of the earlier findings with reference to the discovery of the typhoid organism, antedating the introduction of the agglutinating test, are generally regarded as more or less unreliable, and inasmuch as no adequate data are given with reference to the technical methods employed, and the accuracy with which they are carried out, it seems to me plain that the results of these investigations as reported are far from being a satisfactory demonstration of the presence of these pathogenic organisms in the sediment of this lake.

The opinion is further advanced that there has been an actual multiplication of these disease producing bacteria in the mud of the lake, a multiplication which may have continued for many generations. This conclusion is so at variance with the generally accepted opinion of bacteriologists and sanitary experts, that any person advancing the same should 10547 take a special precaution to fortify his conclusions with very carefully controlled experiments and adequate data so that the course of reasoning which would lead him to draw these conclusions might be closely followed.

It is my opinion therefore that the conclusions established in this paper are not justified from the experiments as presented. I find that this opinion is shared by other bacteriologists and discredit is thrown on the same by the well recognized water expert, Prof. Ferdinand Loeffler, of Greifwald, Germany, who, in his book on "water, and water organisms," page 592, refers to Lortet's experiments, and places after them an interrogation point making it evident that he regards the conclusions drawn from his work as not perfect from the facts as stated.

MR. JEFFRIES: I move to strike out the answer for the reason that it is argumentative and not entirely responsive to the question and for the further reason that the witness undertakes to base his criticisms upon the experiments referred to in the question on the fact that nothing is shown in the report as to the character of the examination or the extent or time that the deposits were contained in the bed of the lake, the 10548 presumption being that competent and proper preparations were made in the analysis of such water at that time and the mere statement of failure to set out the character or extent of the examination constitutes no reason for the witness's assumption that proper precautions were not taken and proper examination made.

MR. TODD: Q. Mr. Fuller in his testimony on page 4218 of my transcript of record, in answer to the question, "Has it ever been demonstrated by bacteriology that typhoid germs have lived in sediment of a running stream?" answered, "It has been demonstrated that they have lived for a long time in the sediment of lakes and I do not consider there is any weakness in the process of reasoning, by which one steps from a lake to a river, provided of course that each of these waters are live waters and not subject to septic action." I will ask you, do you regard the observation in Lake Geneva, as quoted by Mr. Fuller, as a demonstration that the typhoid bacillus has been found to live for a long time in the sediment of lakes?

A. From the observations quoted in the question and 10549 to the answer to the preceding question, I do not consider that the result of observations so reported a demonstration sufficiently full and accurate that a typhoid bacillus so found, as to say that it was capable of living in the sediment of the lake so mentioned for a long time.

Q. Mr. Fuller in his testimony, on page 4219, of my transcript of record, in answer to the question, "Is not the length of time that a typhoid bacillus will live in the sediment more a matter of assumption than a matter of demonstrated proof?" answered, "I consider that it is a very clean cut demonstrated fact that typhoid fever germs may and do and have continued to live in the sediment of running water.". "For what length of time?" "A. I should say for a month or more, possibly in cases for years. Q. Who has demonstrated that it ever lived a year? A. I think conditions existing in moist soil in many rural places of this country where typhoid fever prevails from time to time is proof that typhoid fever germs in the presence of moisture can live for such a time. If that were not so, then there would be an elimination of the typhoid fever absolutely through- 10550 out the rural districts of this and other countiries.

Q. I want to ask you whether you know of any demonstration that shows typhoid fever germs may and do and have continued to live in the sediment of running stream for a period of a year?

MR. JEFFRIES: Now I move to strike out all down to the question which refers to Mr. Fuller, for the reason there is nothing to show that this witness is acquainted with all the examinations and observations that were made of which Mr. Fuller is cognizant, or that the two men, this witness and Mr. Fuller have been informed, identically the same of all the examinations and observations that have been made looking to the life of the typhoid fever germ in moist soil or otherwise in the bed of streams.

A. On the basis of the results as reported by Lortet, which were quoted by Fuller in affecting questions of the life and conditions known to exist with reference to the vitality of the typhoid fever organism when placed in moist soil, also 10551 to the fact that the conditions which here obtain are by no means similar to the conditions which would obtain if such typhoid organisms were deposited in the sediment of running streams, in place of moist soil, I should say I know of no demonstration that affords sufficient proof that the typhoid organism is capable of living for the period of a year.

Q. How near in your opinion does the experiment made by you, Prof. Jordan, and Prof. Zeit, approach the natural conditions?

A. In the experiments which have been detailed by myself, and which also have been previously testified to by Professors Zeit and Jordan, it is my opinion that the conditions under which these experiments were performed approach more nearly to the conditions to which the typhoid organism would be exposed in the water of a running stream than do the experiments previously reported by other investigators, so far as I know or have any cognizance of. Further, that the condition of these
streams as reported by Jordan, Zeit and myself, afford
10552 an opportunity for the exercise of the prejudicial effect
which might come to the typhoid bacillus by reason of the action of the soluble products of bacterial growth which would be capable of exerting their influences under conditions in which this experiment was performed. Further, that this experiment differed from the natural conditions to which the typhoid fever organism would be exposed in the waters of the flowing stream, in that the cultures prepared by us were protected from the effect of a number of environmental factors which would also exert a more or less injurious action and would have a tendency to weaken the virulence of and destroy the vitality of the typhoid organism. I refer to those factors the effect of which have been previously amplified under the heads of sedimentation, influence of dilution, influence of light to a greater or less extent, and the influence of organisms which might be present in the waters of the flowing stream other than
those which are ordinarily present in the samples of
10553 water placed in the parchment sacs in the experiments
detailed.

Q. How do the conditions of this experiment differ from those of the glass bottle experiments such as have previously been obtained in the laboratory experiments on the longevity of the typhoid bacillus?

A. The claim has been made by various investigators, and on this subject there has been published a number of papers, that the conditions which obtain when experiments are conducted on the vitality of typhoid fever organisms, where such experiments are made in glass bottles, favor the longevity of the typhoid germ under these experimentally reported conditions as a certain amount of soluble material is dissolved from the glass, which in some way or other affects the vitality of the contained organism.

Q. Is there any reason for anticipating greater or less longevity on the part of the typhoid bacillus in glass bottles than under conditions of your experiments?

A. In the experiments previously referred to, the influence which glass bottles seem to have on the vitality of the typhoid organism, indicate that the vitality of that or-
10554 ganism is enhanced, and it is capable, therefore, of living longer under the conditions as found in glass bottles than would normally be the case in the experiments which have been performed where typhoid organisms were exposed in parchment sacs. The error which would obtain if glass bottles were used, would be avoided, and it is my opinion that the longevity of the organism when placed under such conditions where it is brought in contact with glass surfaces, is greater than under the conditions referred to in the experiment with parchment sacs.

Q. What do the facts show?

A. The opinion which has been previously advanced is one which was made by taking all the facts which I have any cognizance of, into consideration. Subsequent experiments were also made in the case of the agar block experiments where one set of the blocks inoculated with typhoid organisms in accordance with the method previously described was placed in running water, another set inoculated in a similar manner with the same organism, the same batch of media and under
10555 identically the same conditions was placed in a small glass container, the vitality of the organisms as demonstrated by the special cultures made from said agar block shows that organisms exposed in glass containers were able to retain their vitality for a period of 16 days, whereas those placed in

running water were not found in any case for a period longer than 8 days, and in some instances the longevity of the germ was not more than two or three days.

Q. What is your opinion based upon the knowledge which you possess as to whether the typhoid bacilli coming from the sewers of Chicago and entering the drainage canal, could survive the journey from Chicago to St. Louis, a distance of 357 miles, and be a danger and a menace to the inhabitants of St. Louis, using the water of the Mississippi river for drinking or domestic purposes?

A. By reason of the fact that the previous experiments which have been detailed, show that the vitality of the 10556 typhoid organism is destroyed in the course of not to exceed four days, and that the extent or period of flow which would be necessary for the sewage of Chicago, entering the drainage canal, to pass from Chicago to St. Louis, a distance of 357 miles, would be so great that it would be impossible for the typhoid organism to survive this journey, it is my opinion that the diffusion of such bacilli in the waters of the drainage canal would not be a danger and a menace to the inhabitants of St. Louis, using the water of the Mississippi river for drinking and domestic purposes.

Q. Do the settling basins at St. Louis afford any protection to the citizens of St. Louis against infectious matters of the waters of the Mississippi at the intake tower?

A. Owing to the extensive sedimentation of suspended matter which must take place when the turbid waters of the Mississippi river are introduced into the settling basins, and the fact that such sedimentation does eliminate bacterial life and would eliminate much infectious matter if such 10557 were present, it is my opinion that the interposition of these settling basins between the waters of the Mississippi river and the consumers of water in St. Louis, would afford a material protection to them against the infectious matters which might be present in the waters of the Mississippi river at the intake tower.

Q. Are the settling basins any protection to the citizens of St. Louis against the sewage of Chicago?

A. In as much as the typhoid organisms deposited in the city of Chicago and finding their way into the drainage canal would be killed before the waters filled with such sewage would find their way from Chicago to St. Louis, I must say that the settling basins of the city of St. Louis would afford no protection to the citizens of St. Louis against the sewage of Chicago.

Q. Against what sort of protection would the settling basins be a protection?

A. The protection which would be afforded to the citizens of St. Louis by passing water through the sedimentation basins, would be from those places adjacent to St. Louis, in which the typhoid organism would not be killed during the journey from such places to the sedimentation basins of the St. Louis supply. 10558

Q. Where a settling basin holds a sufficient amount of water to supply a city for a period of 30 days and as the water is taken out for domestic uses raw water is immediately supplied from the open river, and typhoid fever should prevail among the people using such water, what is your opinion as to whether such a condition justifies the assumption that because the basin holds a supply for a period of 30 days, that the typhoid bacillus will live in the water deposited?

A. Water in flowing through a reservoir, does not move with a uniform rate of rapidity, owing to the motility of the water molecules. A stream flows fastest in or near the center, because the friction of the water on the sides of the stream is sufficient to retard the rate of flow. The same principle is operative in the waters of the reservoirs. In another connection I have had occasion to test the effect which variation in this rate of flow would have, as in the case of milk flowing in a continuous stream through a Pasteurizing machine. In this case a small column of milk was passed through a winding machine, and the rate of flow was found to vary from one-half a minute to five minutes, indicating a difference of at least 10 fold. If this is true in a machine of a few inches in diameter, it would be true to a much larger extent in a large reservoir into which water was flowing at one point and flowing out at another. If the capacity of the reservoir was sufficient to hold and settle for a period of 30 days, and typhoid fever should prevail among the people using such a 10559 supply of water, in the light of the above well recognized principle of hydraulics, I would not consider that because a basin holds a supply sufficient for 30 days, that the typhoid fever organism lived for that period of time.

Q. What does the term Epidemiology, embrace?

A. Epidemiology is that science which relates to epidemic diseases.

10560 Under the general term would naturally be embraced a general study of the causation of epidemic diseases, ways in which disease organisms are disseminated in nature, and a consideration of all the data of a bacteriological and chemical nature that would throw any light on the question at issue, geographical distribution of diseases, the effect which variable factors exert, such as age, race, sex, etc., on the susceptibility of the human being toward the disease in question, the influences of other predisposing factors such as density of population, whether in city or country, the study of vital statistics connected with diseases in order to ascertain how these varying predisposing factors influence the death rate, the interpretation of these statistics. In fact, the term epidemiology is an exceedingly inclusive term, and one must understand the significance of scientific methods which have been introduced into the study of diseases, especially in recent years, as shown in the development of the bacteriological science as well as in chemistry.

10561 Q. Have you examined the typhoid statistics of the Illinois, Missouri and Mississippi water sheds above St. Louis?

A. I have.

Q. Have you examined the mortality statistics of the City of St. Louis?

A. Yes sir.

Q. How do you interpret the mortality statistics of the City of St. Louis, in connection with the typhoid statistics on the three water sheds?

A. In interpreting the mortality statistics from typhoid fever in St. Louis, it would be necessary to take into consideration the typhoid statistics obtained on or about these water sheds which contribute water finding its way into the Mississippi, past St. Louis, laying special emphasis upon those statistics which are from cities nearest to the city of St. Louis.

Q. Have you studied the typhoid statistics of the City of Chicago?

A. I have.

Q. Have you studied the typhoid statistics of St. Louis?

10562 A. I have, yes sir.

Q. Now, in the matter of the interpretation of statistics, what methods do you employ?

A. There are two methods that are employed, one which is used largely for comparative purposes known as the mortality percentage method, in which the death rate from any given disease is figured and determined in terms of the total number of deaths in that community. The other method, which is more generally used, and considered more reliable, determines the ratio which exists between the number of deaths from any given disease, based upon the actual population from which the death statistics are collected. This is known as the death rate from that disease per unit of population, usually given in terms of 10,000 to 100,000 persons.

Q. Which one of these methods in your opinion the most correctly gives the typhoid conditions in a given city?

A. I regard the latter method as the preferable method to follow in determining the death rate from any given specific disease, and it should be followed wherever possible.

10563 Q. What is your opinion of the validity of using the mortality percentage method in estimating the typhoid condition in a given city?

A. The method of determining the death rate from any given disease by comparing the mortality of that disease with the total mortality of the community instead of the population itself is liable to introduce error into the results which might readily vitiate the accuracy of such statistics to such an extent as to render them all of much less value than otherwise would be the case. The reason for this is, that when you compare the deaths from any disease to the total deaths, in order to study the increase or decrease of any disease in any community, you are using a wrong basis for comparison. What is waated in any given com-

munity is to know whether a disease is increasing more rapidly than the increase in population. When this rate is based on the ratio between that disease and the total death rate the variation which might and often does occur in the total death rate may be subject to many conditions which now enter
10564 into the consideration of the disease in question. Suppose, for instance, that a serious epidemic of some other disease, like the Bubonic Plague, or yellow fever, should break out, it would be manifestly improper to compare the typhoid death rate in that community before and after such an epidemic and compare the actual number of typhoid deaths, with the total number of deaths, and say that the typhoid was increasing or decreasing, where such a fallacious method was employed.

Q. Is the mortality percentage method regarded as on the whole the most accurate among sanitarians and students of vital statistics?

A. No sir. For the reasons which have just been given, where evident fallacies might creep in where the mortality percentage method was used. You are dealing with two variables, and therefore the liability of misinterpretation is greater than where based upon the actual population.

Q. What are the liabilities of typhoid infection of rivers coming from the rural districts?

10565 A. In view of the fact that the urine of typhoid patients often contain bacilli in great abundance, and in view of the fact that this material is not ordinarily looked upon as dangerous, and therefore is frequently thrown upon the surface of the ground, and in view of the fact that in rural communities greater carelesness prevails in regard to the disposition of this excreta, and even solid material, than would be true where special systems of sewage disposal were present, it naturally follows that the liability of the population to the infection of the river is added to considerably from the rural population.

Q. Is the infection from the rural population less common than from the urban?

A. It is a well recognized fact from statistical evidence, that the percentage of infection designated as typhoid fever mortality at least is not less common among the rural population than in urban communities.

Q. Do you know of any important typhoid epidemics in which infection has come from the rural population?

A. There are a considerable number of typhoid epidemics
which have been reported in which the sources of pollu-
10566 tion have been traced specifically to infection arising
from the rural population. Among these may be mentioned
the Swiss case, which is found in many text books, in the small village of Lausanne, Switzerland. The case mentioned by Gaffky, of a troop of soldiers, in the barracks of Wittenburg, Germany.

The best known case here under American conditions, is that which occurred in the small city of Plymouth, Pennsylvania, in 1884. The epidemic of typhoid fever in Lowell. was traced by Prof. Sedgwick to sources of infection, which were rural in origin, and the very recent epidemics which occurred in Ithaca, New York, and also one which has just passed at Butler, Pennsylvania, where in each instance over a thousand cases of typhoid fever occurred, are both of them undoubtedly attributed in their origin to infectious matter which would be designated as rural.

Q. Are there any reasons why the infection of the rural population is to be especially feared?

A. On account of the carelessness which prevails in the disposition of the dejecta and also the fact that disinfection of
this waste is not carried on so frequently in the country
10567 as it is in the city communities, I would consider that
these were features which render the conditions which
would obtain in the rural population a matter of especial danger.

Q. What is your opinion as to the value to be placed upon the chemical and bacteriological analyses of the water course?

A. If I understand your question to mean the relation which these bear to the determination of the purity of the water, I should regard that evidence which is to be adduced from the chemical and bacterioligical study of such waters, affords us the best possible means which we have at our command to determine whether such waters are likely to serve as carriers of contagion.

Q. What light do the analyses of river water shed upon the problem of self purification of streams?

A. The analytical evidence which can be gathered from the analyses of waters taken at frequent intervals for a con-
10568 siderable period of time and at various points along the course of the stream, give us the best possible means which we have at our command at the present time, of showing the progress of the self-purification which occurs in such running streams where organic matter is gradually disposed of and converted into mineral material.

Q. Are all these sources of information valuable to a sanitarian and epidemiologist?

A. I should consider that the data furnished by bacteriological study, and to some considerable extent, that of chemistry, are the foundation on which a sanitarian or epidemiologist must base his conclusions as to the character of any waters and their liability to be a source of danger and menace.

Q. How is the presence of infectious diseases ascertained?

A. Interpreting your question to mean the presence of disease organisms in the outside environment, I would say that bacteriological methods of analyses which permit of the detection of the specific organisms associated with such
10569 diseases, and the growth and study of the characters which are evident upon artificial media, give us a possible basis upon which such study can be carried on, and the reintroduction of the organisms so isolated into bodies of susceptible animals, prove conclusively the presence of infectious disease organisms.

Q. What are the ordinary modes of causation of infectious diseases?

A. If I interpret your question to mean the way in which disease organisms find access to the human body, I would say that air and water, and food supplies, serve as the passive vehicles for the transmission of contagious organisms. To some extent insects, and by the presence or through the medium of wounds, or bruises, organisms are introduced into the body.

Q. What are the chief sources of infection in typhoid fever?

A. The main sources of infection in typhoid fever are dejecta, coming from the intestinal canal, and within recent years the importance of the urine has been much more clearly recognized than formerly. The urine contains the typhoid organisms

10570 in about 25 to 30 per cent. of all cases, and is often found
in large numbers.

Q. Is it important for the sanitarian and epidemiologist to know the source of infection as well as the results of such infection?

A. It is very important in making any study of any epidemiological question that the sources of infection should be taken into consideration as well as the results of the infection, for the distribution of the disease, and its dissemination may depend largely upon how the organism finds its way into the human being.

Q. Is it a legitimate inference, that because typhoid fever increases in the city, that such increase is due to the increase in infection of the water supply?

A. By no means, for it has been abundantly proven in a considerable number of cases, that the organism of typhoid fever is capable of being introduced into the body in other ways than through the medium of infected water.

10571 Q. What other sources of infection are there in the city besides that coming from its water supply?

A. A very important source of infection, which is found in the case of city population, is that which may come from the infection of the milk supply. The typhoid organism is capable of thriving and growing in milk, which is not the case normally in water, therefore if milk is infected with even an exceedingly small number of organisms, the power of multiplication of this germ, which is able to withstand a considerable amount of acid germs, permits of its development even in milk supplies. This has been determined experimentally, and there is bacteriological evidence through the accumulation of a large number of epidemics of typhoid fever, the origin of which has been traced to the infection of milk.

Q. In the case of St. Louis, which takes its water supply
from the Mississippi river, at the St. Louis intake, and the water
at that point being a mixture of the Missouri, the Mississippi
and the Illinois rivers, assuming the reports of the St.
10572 Louis Board of Health show that the apparent increase
of typhoid fever during the years 1900, 1901, 1902 and

1903 as compared with previous years, is there any scientific reason that would justify the conclusion that such apparent increase of typhoid fever in St. Louis is due to infectious matter coming from the sewers of Chicago by way of the Drainage Canal?

A. Assuming that the reports as to the typhoid death rates for the city of St. Louis, for the years mentioned, are true, and taking into consideration the conditions which obtain in the water sheds of the three rivers mentioned, and the fact that there are sources of pollution from which typhoid organisms might arise which were not as far removed from the City of St. Louis, as would be the case of the City of Chicago, and taking into consideration further, the results of the typhoid experiments which have been made, and which have been detailed in the foregoing answers, I should say that there was no scientific reason which justified the conclusion that the increase of
10573 typhoid fever in St. Louis as reported in the Board of
Health reports for the years 1900 to 1903 inclusive, is due to infectious matter which is derived from the sewers of Chicago by way of the Drainage Canal.

Q. Is there such a thing as a decrease in virulence of the typhoid fever germs?

A. A typhoid fever organism is subject to a considerable change in its power of producing disease. The examination of various strains of typhoid organisms taken from different patients indicate that there is a natural variation in the ability of these organisms to produce death in laboratory animals, and it is also possible to demonstrate experimentally that such variations of virulence may be produced where the organism is grown under artificial conditions.

Q. What do you mean by the decrease in virulence of the typhoid fever germ?

A. The decrease in virulence means that the organisms lose wholly or in part their ability to produce an infective con-
10574 dition in the blood of the susceptible host.

Q. What evidence have you upon which to base such an opinion?

A. The evidence which I can adduce to support this opinion, is based upon experimental tests made in the laboratory on the gradual diminution in virulence of such organism when cultivated upon artificial nutrient media.

10575 Q. Have you made a study of the so-called germ diseases?

A. In connection with my studies on bacteriology, it has been necessary for me to make special studies of the various germ diseases caused by bacteria and other lower forms of life.

Q. Do these diseases caused by germs come within the scope of your study?

A. Many of the diseases of man and animals of a transmissible nature are caused by the injection of parisitic organisms belonging to bacteria, and hence in the work of bacteriology, consideration of these diseases and the diseased under which they are introduced, is properly within the scope of my study.

Q. Have you made any study upon typhoid fever and malarial fever from the standpoint of the bacteriologist or clinician?

A. From the bacteriological point of view it has been possible for me to make a study of the diseases of typhoid fever and malaria, and the organisms which are known to possess

10576 a causal relation to those diseases.

Q. In connection with your study as you have detailed, have you taken up the question of the proper diagnosis of fevers known as typhoid fever and malaria?

A. In connection with such studies it is absolutely necessary in order to make a proper diagnosis of such fevers, to take up the study from the laboratory point of view, and determine by examination of the blood whether the disease causes a reaction or not, and in connection with such studies I have performed these tests.

Q. Have you had any experience in the diagnosis of these fevers either in the laboratory or at the bedside?

A. In connection with my studies of these diseases, and also in connection with routine work of the diagnostic laboratory with which I am connected, I have had experience in the study of these diseases and their diagnosis.

Q. Have you studied these diseases sufficiently to give an expert opinion on them?

10577 A. In connection with the diseases previously mentioned this experience has been sufficient, together with the study of the literature relating to this subject to warrant me in giving an opinion as to whether diagnoses of typhoid fever or malaria are correct or not.

Q. What is typhoid fever in its clinical diagnosis?

A. Typhoid fever is a disease which is confined to man, and is widely distributed throughout the temperate zone. The symptoms of the disease are not always specific, but in general it is characterized by the production of fever which often begins in a relatively obscure manner, the temperature rising from day to day until it reaches its maximum, and then gradually declining. The symptoms of the disease most frequently noted are headache, sometimes with more or less tympanitis, the production of rose colored spots on the abdomen, which, however, in some cases do not appear, the enlargement of the spleen, accompanied sometimes with tendernesses, and frequently copious bleeding at the nostrils. The lesions of the disease are 10578 usually manifested in the intestines, affecting peyers patches and the solitary glands, causing an ulceration sometimes through the intestinal wall which may result in the production of a secondary complication of peritionitis.

Q. What is intermittent fever and its clinical diagnosis?

A. Intermittent fever, so called, is a fever which is characterized by a marked variation in the temperature where it falls to a normal after a rising temperature and then a subsequent rise again, which is followed the next day by a fall.

Q. What is remittent fever and its clinical diagnosis?

A. Remittent fever, so called, is one of the older expressions which is used to designate a type of fever in which the variation in temperature does not fall to the normal, but which is marked by frequent and rapid oscillations in temperature.

Q. What is typho-malarial fever and its clinical diagnosis?

A. Typho-malarial fever is again one of those older designations 10579 which is used to designate a type of fever and is employed to include many low types of fevers that with the better diagnostic means which are now available especially since the introduction of the Widal test for typhoid fever can usually be differentiated into genuine typhoid or genuine malarial fever. Rarely does it happen in communities where both of these fevers are universally present, that the organisms capable of producing these specific distinct diseases are found in the same case simultaneously.

Q. What is congestive fever and its clinical diagnosis?

A. Congestive fever again is an indefinite term applied to low fevers that have no well marked characteristic. Its most marked symptom is more or less acute congestion. It has no accurate clinical significance as applied to any specific disease.

Q. What is simple continued fever and its clinical diagnosis?

A. The type of fever in which the course of the febrile changes is more or less continuous. It has no marked characteristic symptom.

10580 Q. Are remittent, intermittent, typho-malarial, congestive and simple continued fevers distinct types of diseases and so recognized by bacteriologists and clinicians?

A. The terms remittent, intermittent, typho-malarial, congestive and simple continued are relics of old methods of description which attempted to differentiate these febrile changes, merely on the basis of the symptoms which are most evident. They are not recognized by working bacteriologists or clinicians of the present time as being satisfactory names for specific types of fevers.

Q. What significance do you attach to these terms as applied to fevers where they appear in vital statistics?

A. The use of the terms remittent, intermittent, typho-malarial, congestive and simple continued as applied to vital statistics collected under present day conditions would in my judgment indicate that the causes of deaths were not
10581 classified as they should be and would therefore lead one to place less reliance on such statistics than would be the case if they were more accurately classified.

Q. Assuming that the number of deaths reported as occurring from typhoid fever in the City of St. Louis as evidenced by the annual reports of the Board of Health in the City of St. Louis Health Department is as follows, from 1890 to 1903:

1890	140
1891	165

1892	441
1893	215
1894	171
1895	107
1896	106
1897	125
1898	95
1899	131
1900	168
1901	198
1902	222
1903	288

10582 and assuming further that the number of deaths reported from the same reports under heading, Remittent, Intermittent, Typho-malarial, Congestive and Simple Continued fevers is as follows, from 1890 to 1903:

1890	226
1891	296
1892	326
1893	284
1894	179
1895	155
1896	177
1897	172
1898	134
1899	148
1900	112
1901	80
1902	102
1903	91

10583 do the number of deaths reported as occurring from typhoid fever alone in the City of St. Louis, properly represent in your opinion the total number of typhoid deaths actually occurring in that city?

A. From the study of the statistics mentioned in the foregoing question and from the general knowledge of the relation which these diseases bear to each other and the liability of making an improper diagnosis between them, I do not consider that the number of deaths reported in the vital statistics of the board of health of the city of St. Louis for the years 1890 to 1903 inclusive, represent the total number of deaths from typhoid fever which actually occurred in that city in that interval.

Q. What reasons have you for stating that they do not?

A. Taking into consideration the fact which is well recognized by sanitarians, that fevers classified under the heads of remittent, intermittent, typho-malarial, congestive and simple continued are in a large measure found to be fevers which by means of modern diagnostic methods would be recognized as typhoid fever, it is my opinion that the statistics which include
a large proportion of fatalities as due to fevers of this
10584 class, do not represent the true condition which obtained
in that city with reference to the total typhoid death rate.

Q. To what do you attribute the failure of these statistics assumed in the hypothetical question, to properly disclose the number of typhoid fever deaths occurring in St. Louis?

A. In my judgment the value of the statistics assumed in the hyphothetical question rests in a large measure on the more or less imperfect diagnosis which has been made by physicians reporting those deaths to the City Health Department.

Q. Why is it that doctors employed the terms, remittent, intermittent, typho-malarial, congestive and simple continued fevers that are recognized as being either typhoid or malarial?

A. Inasmuch as many practicing physicians are not personally familiar with modern diagnostic methods which are now employed in the most advanced practice with the diagnosis of
typhoid fever and malaria, and the differentiation of one
10585 from the other, it frequently follows that the old expres-
sions based upon the symptoms of the fever, which used to be used, are frequently used at the present time by such physicians when reporting the cause of death.

Moreover, it frequently occurs that symptoms noted in cases of fever are not sufficiently distinctive to enable a physician to recognize with certainity whether he is dealing with genuine typhoid fever or malaria, and consequently, owing to the tendency to retain these old terms in the descriptions of diseases, it naturally follows that many of the typical cases, which are more or less obscure in their symptoms, are reported in the cause of death as remittent, intermittent, typho-malarial, congestive and simple continued fevers.

Q. Do you know of any city in the country where the death rate from malarial fever alone is as high as in the city of St. Louis, as evidenced by the total number of deaths assumed in the hypothetical question under the heading intermittent, 10586 remittent, typho-malarial, congestive and simple continued, occurring in the reports of the board of health of the city of St. Louis?

A. Inasmuch as the death rate from such malarial fevers as occur in the United States of America is comparatively insignificant (there being practically no pernicious or tropical malaria which is exceedingly fatal in this country except where imported) it of necessity follows that no city has as high a death rate from pure malaria alone as is represented in the number of deaths reported in the St. Louis statistics and included in the terms, intermittent, remittent, typho-malarial, congestive and simple continued, which are assumed in the foregoing hypothetical question.

Q. What proportion of deaths in the column under the heading, remittent, intermittent, typho-malarial, congestive and simple continued, assumed in the hypothetical question as occurring in the City of St. Louis, as evidenced by the reports of this board of health in your opinion should be classed as typhoid?

A. In my opinion it is practically impossible for any one to give an accurate idea as to what percentage of the 10587 deaths reported under the heading, remittent, intermittent, typho-malarial, congestive and simple continued, assumed in the hypothetical question as occurring in the City of St. Louis, inasmuch as a majority of the cases terminating fatally are now diagnosed as typhoid fever, it is undoubtedly true that a large proportion of these deaths so reported should be classed as typhoid fever.

Q. What proportion is due to malarial fever, of the deaths in the column under the heading, remittent, intermittent, typho-malarial, congestive and simple continued, assumed in the hypothetical question as occurring in the City of St. Louis, as evidenced by the reports of this board of health in your opinion, what proportion should be classed as malarial?

A. Owing to the fact that the disease of malaria as it exists in the United States is a disease resulting in an exceedingly low mortality, it is undoubtedly true that the number of cases reported in the foregoing hypothetical question which should be classed as genuine malaria, is exceedingly
10588 small. This opinion is based upon the fact that the hospital records in southern cities where malaria is more or less abundantly prevalent, and where modern methods of diagnosis are widely used for the recognition of the disease, that the fatality from this disease is so small as to be practically negligable.

Q. What do the mortal statistics of malaria show in cities where careful attention has been paid to malarial fevers as regards the number of deaths occurring from malarial fever?

A. In regions where malaria is known to frequently exist, and where the best modern methods of diagnosis are widely employed, it is noteworthy that the number of deaths reported as due to genuine malaria fever have been greatly reduced since the introduction of these methods. The results of this character are shown directly by the history of malarial cases which have been recorded in the Johns Hopkins Hospital
10589 situated in Baltimore, Maryland. Malaria used to be very frequently reported as the cause of death in the city, but with the introduction of the methods of making blood examinations, the number of cases now reported show that the total number of deaths has been reduced to a mere fraction of what used to be reported.

Q. Is it generally recognized by bacteriologists and clinicians in classifying typhoid fever in one column, and intermittent, remittent, typho-malarial, congestive and simple continued fevers in another column, in the board of health reports of cities, that it is an improper classification from a scientific standpoint as affording a true indication from the mortality from typhoid fever and malaria?

A. Inasmuch as modern methods of diagnosis have enabled the clinician to classify a larger proportion of specific febrile causes under the heads of typhoid fever and malaria, which in

former years, before the introduction of these methods, were generally classified and based on symptoms of the disease under the heading, intermittent, remittent, typho-malarial, con-
10590 gestive and simple continued, it is well recognized by bacteriologists and clinicians that the continuation of the use of these traditional terms is merely to describe the symptoms of the diseases, that indicate their specific character, and is an improper classification from the scientific standpoint, and that where such a classification is followed, it is no true indication of the mortality which exists with reference to typhoid fever and malaria.

Q. Assuming that the reports of the Board of Health of the City of St. Louis, by the month, from '95 to 1903, inclusive, under the heading of typhoid fever, which for the purposes of convenience is designated A, in the table that follows, and that intermittent, remittent, typho-malarial, congestive and simple continued, for the sake of convenience is designated as B, in the table that was prepared by Prof. Jordan and given in his testimony, is based upon said reports of the City Board of
10591 Health of St. Louis, will you please state what construction you place upon this table as showing the relative mortality from typhoid fever, and malarial fever in the city of St. Louis during the period covered by the foregoing table?

A. In view of the fact that the mortality from genuine malaria in the United States is exceedingly small, it is considered that a large number of deaths which are reported in the reports of the board of health of the City of St. Louis in the year 1895 to 1903 and designated as B, in that table, must include in addition to the exceedingly small number of deaths which are caused by the type of malaria which prevails in the United States, and inasmuch as the fevers which are most likely to occur are either malarial or typhoid fevers, and taking into consideration the low mortality which really occurs in malaria, I should consider that it was generally probable that a large proportion of these diseases which are designated for convenience as Column B, for the respective years, should be placed in a column which includes the reports of the fatalities due to typhoid
10592 fever.

Q. Assuming that an added total of deaths from typhoid fevers and deaths from intermittent, remittent, typho-malarial, congestive and simple continued fevers as they appear in the reports of the Board of Health in the City of St. Louis, is as follows, from 1890 to 1903:

1890	361
1891	781
1892	767
1893	499
1894	350
1895	262
1896	283
1897	297
1898	229
1899	279
1900	280
1901	278
1902	324
1903	379

What do these totals as above indicated, represent in your
opinion as to the mortality conditions of typhoid fever in
10593 the City of St. Louis, covering the period as above indicated,
after allowing in said remittent, intermittent, typho-malarial, congestive and simple continued fever column, such proportion as being typhoid fever as in your opinion you should allow. What is your opinion as based upon the statistics as assumed in the foreging hypothetical question, as to the typhoid deaths under remittent, intermittent, typho-malarial, congestive and simple continued fever deaths, in the City of St. Louis, as to whether said statistics show an increase or decrease in the typhoid fever mortality in the City of St. Louis, since '99?

A. Assuming that by far the larger proportion of the deaths which are reported in the reports of the Board of Health of the City of St. Louis, for the City of St. Louis, for the years covered in the foregoing question under the head of intermittent, remittent, typho-malarial, congestive and simple continued fevers, were really deaths which are attributable to the disease of typhoid fever and therefore should be added to the

10594 totals which were actually reported in that city for those years under the caption Typhoid Fever, and taking into consideration the statistics presented in the foregoing question, I should consider that the said statistics do not show material alteration which could be deduced with certainity in the typhoid fever mortality of the City of St. Louis, from the years '99 to 1903.

Q. Assuming that two circular letters were issued in the fall of 1900, another one issued in the fall of 1901 by the Health Commissioner of St. Louis calling attention of physicians to the fact that the law required them to report all cases of typhoid and all deaths from typhoid and at the time those letters were sent out the question of the opening of the Drainage Canal was being agitated by the public press of St. Louis, and there was considerable discussion and investigation was going on at that time in regard to the analyses of the samples so collected, etc., and was attracting considerable attention, from your examination of the statistics of St. Louis, as heretofore assumed in hypothetical questions heretofore asked you, for the years 10595 1901 to 1903, as compared with previous years, does the effect of such letter, assuming that the same had been sent to the doctors by the Health Commissioner of the City of St. Louis, manifest itself in these statistics?

A. In comparing the statistics assumed in the foregoing hypothetical question, I should consider that such data did manifest itself in the statistics.

Q. In what way does the effect of such letter appear from the statistics?

A. Take the statistics as to the mortality from typhoid fever and the mortality from those diseases which are included in what we may call typho-malarial, in the column designated in the previous statistics as Column B, taking into consideration the fact that such statistics show a marked diminution in the number of the cases reported in the typho-malarial column for the year 1900 and the year 1903 inclusive, and that for the same period a marked increase is noted under the head of deaths from typhoid fever. Further taking into consideration the fact that circular letters were issued in the fall of 10596 1900, and 1901 respectively, by the Health Commissioner of the city of St. Louis calling the attention of physicians to the requirements of the law as to the reporting of all cases and deaths resulting from the disease of typhoid fever, it is evident from the data of the report that the issuance of these letters by the Health Department of the city of S. Louis to the physicians of that city does manifest itself in the statistics as reported.

Q. From your examination of the typhoid and typho-malarial group of deaths as assumed in the foregoing hypothetical question, what is your opinion as to whether these two tables taken separately correctly show the typhoid conditions of the City of St. Louis for the period mentioned?

A. If consideration is given to either of the columns designated typhoid and typho-malarial death reports as reported by the board of health of the City of St. Louis, it is my opinion that neither of these reports of the fatalities do express the actual typhoid mortality of the city of St. Louis for the period mentioned.

10597 Q. Upon what do you base your opinion that they do not correctly show the typhoid conditions in the city of St. Louis, taking them separately?

A. This opinion is based upon the fact that it is highly probable that a large majority of the cases reported in the column designated B, in the foregoing questions, really were cases of typhoid fever, and further taking into consideration the effect which would be produced by the issuance of letters mentioned in the foregoing questions, it would lead to a more correct diagnosis of the disease of typhoid fever and the report of the same under the caption of Typhoid Fever, I should consider that the results as presented in the foregoing questions do not correctly represent the typhoid conditions which actually occurred if these tables are considered separately.

Q. From your knowledge of these classes of fever mentioned in the foregoing cloumns in the statistics as heretofore assumed, how should they be treated by bacteriologists

10598 and clinicians and statisticians in order to arrive at the true typhoid fever mortality in the city of St. Louis?

A. Owing to the liability to confusion which must of necessity exist from the use of old traditional terms which are descriptive more of the symptoms than the specific nature of the disease in question, and the direct liability of the confusion of these terms with that of typhoid fever, I should consider that from the standpoint of the bacteriologist, clinician or statistician, in order to get at the true typhoid mortality which would exist in the city of St. Louis, that it would be necessary to add to the statistics which they have reported as typhoid, a large proportion at least if not practically all of the cases which have been reported under the caption which has been designated in previous questions as Column B, to those figures in the given typhoid fever cases.

Adjourned until 10:00 A. M., February 20, 1903.

10599 10:00 a. m., Saturday, February 20, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. H. L. RUSSELL,

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Assuming that the table testified to in evidence by Professor Jordan, as compiled from the typhoid fever mortality and typho-malaria, etc., of the health reports of the City of St. Louis, and based upon the population of the City of St. Louis, for the years 1890 and 1900, according to the United States Census reports, and the intervening years estimated by 10600 Farr's formula, is given by Professor Jordan. Will you please state what is your opinion, based upon the tables heretofore read, as to whether typhoid fever has increased or decreased in St. Louis since 1900 over the conditions that obtained in St. Louis prior to 1900?

MR. JEFFRIES: I object to the question for whether the table is correct or incorrect it states on its face what it is worth and the court can draw conclusions upon it as well as the witness.

A. Taking into consideration the fact that the circulars issued by the Board of Health of the City of St. Louis have unquestionably had their influence in increasing the accuracy of the typhoid statistics since the issuance of that circular in 1900, and that the great majority, if not practically all of the deaths reported before the year 1900 under the head of remittent, intermittent, congestive, typho-malarial, and simple continued fevers were actually cases of typhoid fver, and, therefore, should have been included in any statistics which showed the total amount of typhoid fever in the City of St. Louis for that time and assuming the accuracy of the compilations which have been 10601 made by Professor Jordan, based on the relative increase of population as determined by Farr's formula when to the typhoid fever death rates there have been added from 50 to 100 per cent. of all recorded deaths which have been reported under the head of remittent, intermittent, congestive, typho-malarial and simple continued fevers, and which in my judgment represent data showing the actual amount of typhoid fever which did occur for the periods mentioned much more correctly than is shown by consideration of the reported deaths, as reported in the board of health reports of the City of St. Louis under the caption of typhoid fever alone, I should consider that the actual number of typhoid deaths which have occurred in St. Louis since the year 1900 shows no increase over the death rate in that city from this disease for the period mentioned prior to that time, with the possible exception of the recognized epidemic which occurred about the year 1892.

Q. From a careful analysis of the typhoid and typho-malarial mortality statistics as they appear in the foregoing hypothetical questions, and from your knowledge of the conditions obtaining in any city using a water supply 10602 from a river, as well as all other sources of knowledge which you possess upon this question, what is your opinion as to whether there is an increase in typhoid fever in St. Louis since January, 1900, over conditions that prevailed in St. Louis prior to that time?

A. Taking into consideration the fact that the typhoid statistics alone, as reported in the board of health report, for the City of St. Louis, do not represent the actual conditions which occur in that city with reference to this disease, but that these statistics should be increased by a large proportion, if not all of the deaths which are reported under the caption of remittent, intermittent, typho-malarial and simple continued fevers, and that when such additions are made for the period which is covered in the foregoing questions, and comparisons are instituted between the typhoid mortality in St. Louis, as modified by the additional deaths which should be computed in the typhoid statistics and now reported under other causes, when these statistics are compared with the typhoid mortality statistics in other cities where similar types of water supply are employed for municipal purposes, it is my opinion that these 10603 statistics show that there has been no increase in the actual number of typhoid deaths which occurred in the City of St. Louis from January, 1900, to 1903, inclusive, when the typhoid death rate for this period is compared with that which actually prevailed in the City of St. Louis for the period embraced between the years 1890 and 1900, inclusive.

Q. Will running water purify itself so as to be free from pathogenic bacteria which may be placed therein?

A. In the operation of natural courses running water undergoes processes of purification, and frees itself from pathogenic organisms in due course of time.

Q. State your opinion as an expert on water supplies for cities and towns as to whether or not the water of the Mississippi river west of the center thread of the main channel of the said river, below the mouth of the Illinois river, and down to the intake tower of the St. Louis waterworks at the chain of rocks, is less valuable for drinking purposes and more liable to carry water borne diseases such as typhoid fever and cholera now than it was before the sewage from the sanitary district of Chicago was running into the drainage canal and through it into the Illinois river?

A. If the typhoid organism is killed out in the Illinois river in the period of time which is less than the necessary time for the flow of the water from the sewers of 10604 Chicago to the City of St. Louis, and assuming that the destruction of the typhoid organism is an index of the destruction of pathogenic organisms in water, and on the basis of the experiments which have been previously detailed in which proof is adduced to show that the vitality of the typhoid organism is destroyed in a much less time than is necessary for the flow of water from Chicago to St. Louis, it is my opinion that the waters of the Mississippi river west of the center of the main channel of the said river and below the mouth of the Illinois river, down to the intake tower of the St. Louis waterworks at the chain of rocks, is not less valuable for drinking purposes and not more liable to carry water borne diseases now than it was before the sewage of the sanitary district was run into the drainage canal and through it into the Illinois river.

Q. State whether or not an increase in the speed of the current of the Illinois river, by reason of the added volume of water of the drainage canal would affect the amount of sedimentation that might and must occur in the Illinois river and if it does affect it how and in what manner?

A. An increase in the speed of the current of the Illinois river, by reason of the added volume of water in the drainage canal would probably alter the manner of sedimentation that would occur in the waters of the Illinois river from what was the case before the addition of such water from the drainage canal occurred. The addition of this added volume of water from the drainage canal carries with it a larger amount of suspended organic matter, and therefore increases the amount of suspended material which would be present in the waters of the Illinois river and consequently the addition of this added drainage canal water would increase the amount of sedimentation which would otherwise occur. 10605

Q. What effect, if any, would the increased speed of the current in the Illinois river have upon the time within which sewage from Joliet, Peoria and other towns on the Illinois river have if emptied into the waters of the Mississippi, if the same are so removed as compared with the conditions that existed at the time it might have taken before the added volume of water from the drainage canal was put into the water of the Illinois?

A. If it did not cause an overflow of the banks of the stream, the increase in the speed of the current would carry suspended matter farther down stream, but it is my opinion that the removal from the river of the sewage from the towns mentioned would be performed before such sewage reached the Mississippi river, so that it would not materially alter the condition of the Mississippi river, except in the case of suspended salts, such as chlorine and nitrates which are not eliminated from the water in the purification of the sewage which might be discharged into such stream. 10606

Q. If water is made more clear and less turbid than it was before the opening of the drainage canal by an added volume of water being placed therein, will such bacilli as typhoid have more or less a tendency to go down to the bottom of the stream than they had prior to the water being rendered less turbid?

A. In case water is made more clear and less turbid by the addition of other volume of water, it would lessen the sedimentation which would normally occur so far as bacteri are concerned.

Q. If an increased volume of water in the Illinois by the addition of the water of the drainage canal would make an increased speed in the current of the Illinois river, would that increase in said current have an effect in increasing or
10607 diminishing the typhoid and liability to typhoid and other water borne diseases on the part of the inhabitants of the State of Missouri using the waters of the Mississippi river for drinking purposes below the mouth of the Illinois river?

A. From the facts of the experimental evidence which has been previously adduced that the typhoid organism would fail to live for a period of time which would be covered by the flow of water from Chicago to St. Louis, it would therefore follow that an additional volume of water discharged by the waters of the drainage canal, which would cause an increased speed in the current of the Illinois river, would not have any effect in increasing or diminishing the typhoid fever or the liability of the inhabitants of the State of Missouri using the waters of the Mississippi river below the mouth of the Illinois river to contract from such waters typhoid or other water borne diseases.

Q. Professor Sedgwick, in answer to this question: "What do you say as to the longevity of the germ of typhoid fever as a general proposition in connection with sewage polluted water?" answered, among other things: "My belief is that in a sewage polluted stream the typhoid germ might live in gradually
10608 diminishing numbers for weeks or months or even years." What is your opinion as to whether typhoid bacillus will live in the sewage polluted streams in gradually diminishing numbers for weeks or months or even years?

A. As it has been shown by experimental evidence that the typhoid organism dies out with a special rapidity in sewage polluted waters, it is my opinion that under the conditions which would exist in a sewage polluted stream that the typhoid organism would not live in gradually diminishing numbers for the period of time which is embraced in the foregoing question.

Q. Assuming that the number of bacilli coli communis in the waters of the Illinois River at Grafton are at intervals no greater than the number contained in it above the opening of the drainage canal, do you consider for that reason that the water is at all times no more dangerous than formerly?

Mr. Jeffries: Objected for the reason that the evidence on the part of the defendants show that since the opening of the drainage canal there has been an added volume of water to the Illinois River at the rate of something like 300,000 cubic feet per minute, that such water was not added to the Illinois River to any such extent prior to the opening of the canal, and
10609 the testimony of the defendant further shows that typhoid fever germs die out much more rapidly in highly polluted sewage material than in the waters of natural streams, and that from the defendant's own testimony the evidence shows that typhoid fever germs will live longer in the waters of the Illinois River since the opening of the canal than prior thereto, and for that reason the question is inconsistent and contradictory and it conflicts with the previous testimony of this witness and all other witnesses introduced by the defendant.

Mr. Todd. In reply I will state that this question, on page 3454 of the transcript of the record which I have, is the identical question which was asked by complainant's attorney of Professor Sedgwick, and I have a right to assume that complainant was as well versed with conditions that obtained upon the Illinois River and all scientific propositions relating to that river at the time this question was asked as he is now.

Mr. Jeffries: It is not a question as to whether or not the complainant thought the question was a competent question for Professor Sedgwick, but whether or not it is competent by taking into consideration all the facts proven in evidence by the defendants themselves.

10610 A. On the assumption of the conditions as stated in the foregoing question that no marked variation in numbers of colon bacteria occurred when comparisons are made of the colon content of the waters of the Illinois River before and since the opening of the drainage canal, I should consider that the results so assumed would indicate that there had been no material change in the water during this time and that it was not more dangerous since the opening of the drainage canal than was the case previous to this opening.

Q. Professor Sedgwick, in answer to the following question: "Assuming that the germs of typhoid fever coming from the sewers of Chicago and passing by way of the drainage canal to Lake Peoria be in large numbers deposited in the bed of Lake Peoria, for the period of a month say, do you consider that typhoid germs would be entirely destroyed at the end of that time in that deposit?" answered "No sir." What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited there in the bed of Lake Peoria for a period of a month, and as to whether or not typhoid germs coming from the drainage canal, under the conditions as they
10611 exist, would live for a period of a month and not be destroyed before the end of that period?

A. I consider the assumption that typhoid fever could pass from the sewers of Chicago, by way of the drainage canal to Lake Peoria, and be deposited there in the bed of that lake for a period of one month as one that is untenable and in the light of experimental inquiry not in accord with the facts, and it is my opinion that under no normal conditions which could obtain in nature as they now exist that the typhoid germs would be able to pass from Chicago to Peoria and not be destroyed before the end of the period covered by the question.

Q. Professor Sedgwick, in answer to the question "Assuming that typhoid fever germs coming from the Chicago sewers are deposited in large numbers in the lakes and slack water portions of the Illinois River above Peoria, do you or do you not consider that flood conditions such as would scour the deposits from the beds of the stream would cause the water leaving Peoria Lake to contain at times more infectious and dangerous pollution than are at present in the diluted sewage entering the Bear Trap Dam at the foot of the drainage canal?" answered: "I think that at times it might." What is your opinion taking into consideration all that you know about
10612 the conditions in the drainage canal, the Desplaines River and the Illinois River as a bacteriologist and epidemiologist as to whether such a condition at times might exist?

Mr. Jeffries: I move to strike out and eliminate all that was said with reference to Professor Sedgwick and his answer thereto for the reason that the question as put to Professor Sedgwick may be put to this witness without reference to what Professor Sedgwick may have or may not have said.

A. Taking all of the conditions into consideration that obtain in the drainage canal, the Desplaines and the Illinois River, as to the probable longevity of the typhoid bacilli in the waters of such stream, I should consider that at no time under natural conditions would such conditions exist as would cause the waters of the Illinois River leaving Lake Peoria to contain more infectious and dangerous pollution than would exist in the diluted sewage of the drainage canal, passing the Bear Trap Dam.

Q. What is your opinion as to whether typhoid fever germs coming from Chicago sewage are deposited in large numbers in the lakes and slack water portions of the Illinois River above Peoria?

10613 A. Inasmuch as the rate of flow is such that Chicago sewage can not be carried from the city of Chicago to Lake Peoria in a period of time that would be within a period of time that the typhoid organism would be able to retain its vitality, it is my opinion that large numbers of typhoid organisms derived from the Chicago sewage would not be found in Lake Peoria above the city of Peoria.

Q. What is your opinion based upon all the knowledge which you have of conditions at Lake Peoria, as a bacteriologist and sanitary expert, as to whether at any time, under any conditions, the number of typhoid fever germs at that point is ever as great as they are at the Bear Trap Dam, at the end of the drainage canal?

A. Considering all of the conditions involved, and for the reasons previously explained, I should say that my opinion is that at no time, under natural conditions would the number of typhoid organisms even be as great at Lake Peoria as they would be at the Bear Trap Dam.

Q. Do you know of any evidence based upon any investigations made by yourself or by any one else that justifies the conclusion that at any time, under any conditions, there are larger number of typhoid fever germs at Peoria than at the Bear Trap Dam?

10614 A. I know of no evidence whatever that justifies the conclusion that at any time larger numbers of typhoid organisms would be found in the waters of Lake Peoria than would be present at the Bear Trap Dam. On the contrary there is every reason to believe, as a result of the investigations of my own and those made by Professors Jordan and Zeit, that the opposite conditions would prevail and that the organisms of typhoid fever which might be present at the Bear Trap Dam would be destroyed entirely before reaching Lake Peoria, in the natural flow of the river.

Q. Do you know of any evidence scientifically secured or otherwise that shows that accumulations of typhoid germs are found in lakes and slack waters basins of rivers and remain there in storage in vast numbers for any considerable period of time in a virulent state and are suddenly flushed out by freshets, so that greater numbers of typhoid fever germs are present flowing in a stream a considerable distance from the source of pollution in greater quantities than they exist at the source of pollution?

A. Inasmuch as the typhoid organism is incapable of 10615 thriving in normal raw waters or in other waters contaminated with organic matter and therefore they are more or less rapidly destroyed and would therefore be present in diminishing numbers the longer they remain in water, there is no evidence that I know of secured under scientific conditions or otherwise that would show that the vitality of the typhoid organism would be contained in the sediment of streams which are saturated with water and soluble substances dissolved in that water for considerable periods of time, and I do not believe that the conditions would ever obtain under a natural state of affairs so that a large number of typhoid organisms would be found present in a stream a considerable distance from the source of pollution which were larger than would exist under the original source of such pollution.

Q. As a sanitary expert, availing yourself of all chemical and bacteriological knowledge which is available to you, what is your opinion as to whether a typhoid bacillus lying in the sediment of a polluted stream for a period in excess of sixty days would be able to cause typhoid fever when taken into the human system after it had remained in such sediment for that length of time?

10616 A. Recognizing the fact that the typhoid organism is incapable of multiplication in either water of a polluted stream or the sediment of such stream, and recognizing further the fact that this diminishing vitality is undoubtedly coupled with a gradual diminution in the virulence of the organism and recognizing the fact which has been experimentally determined by competent bacteriologists that strains of typhoid bacillus have been found with such low degree of virulence that they were incapable of producing the disease of typhoid fever in the human system, and recognizing, moreover, the inability of the typhoid organism to retain its vitality even for the period of time mentioned, it is my opinion taking all of these facts into consideration, that the typhoid organism exposed under the conditions assumed for the period of time assumed, would not be able to produce typhoid fever.

Q. What is your opinion as a sanitary expert as to whether polluted matter or typhoid bacilli coming from the sewage of Chicago, through the drainage canal, deposited on the bottom of the Desplaines and Illinois Rivers, between Chicago and Peoria, can remain there for a period of from thirty to sixty days, and yet retain its dangerous qualities as well as their pathogenesis?

10617 A. For the reasons which were detailed in the answer to the foregoing question, as to the conditions which would prevail when the typhoid bacillus or polluted matter would be deposited in the bottom of a stream for the period assumed in the foregoing question, it is my opinion that if the organism was deposited for that period, it would not be capable of exerting a pathogenic effect or in any way retain its dangerous qualities.

Q. Now, assuming that the only pollution of the river was that contributed to it by the Chicago Sanitary District and having in mind the large amount of typhoid fever existing in said district do you or do you not consider the effect of the time interval, dilution and sedimentation occurring between Chicago and Grafton would be such as to permit the water as it enters the Mississippi River at all times to be free from the liability of producing water born diseases in those who drink it?

A. Inasmuch as the influence of the particulars which have been assumed in the question would be sufficient to cause the loss of vitality of the typhoid organism which was deposited in the waters of the Illinois River from the sewage of Chicago it would therefore follow that the water which enters the Mississippi River at Grafton would be free from the liability
10618 of producing any water born diseases among persons who should drink such water.

Q. Assuming that no other pollution or infection reaches the river save that which it receives from the sanitary district of Chicago, from your knowledge as a bacteriologist and sanitary expert have you had any personal experience or knowledge which would lead you to believe that the water of the Illinois River at Grafton is infected with the sewage from Chicago, and if the said water enters the Mississippi River becoming mixed with the water of that river would it become a menace to the health of the inhabitants of the Missouri shore of the Mississippi River using that water for drinking purposes at points below, on the Missouri shore?

A. Owing to the fact that the pollution or infection which would be deposited in the Illinois River from the sewers of Chicago would be practically purified by the time it has been carried for a portion of its way down the river on the way from Chicago to Grafton, it would naturally follow that the waters of the Illinois River which entered the Mississippi River
10619 at Grafton would not be a menace to the inhabitants of the Missouri shore on the Mississippi River if such water was used for drinking purposes at points below on the Missouri shore.

Q. Is there anything based upon your knowledge as a bacteriologist and sanitary expert which you know would lead you to believe that the water coming from the Illinois River at Grafton was infected from the sewers of Chicago, and assume that the waters of the Illinois River mixed with the waters of the Mississippi River at Grafton and subsequently mixed with the waters of the Missouri River at its mouth, do you consider the water of the Illinois River, thus commingled with the waters of the Mississippi and Missouri Rivers a menace to the health of the inhabitants of Missouri, living upon the Mississippi River, using the Mississippi River water for domestic and drinking purposes at points below Grafton on the Missouri side of the Mississippi River?

A. I would not consider that the admission of the waters of the Illinois River, in accordance with the conditions as described in the foregoing question would cause any meance to the inhabitants of the Missouri shore when the waters of the Illinois River were discharged into the Mississippi and com-
mingled with the waters of the Missouri River and Mis-
10620 sissippi River, and when the waters of the united streams
was used for drinking purposes by persons living below
Grafton on the Missouri shore.

Q. Is there any evidence, bacterial or otherwise, that can establish the conclusion that the waters of the Illinois River at Grafton are infected by the sewage from Chicago, eliminating all other sources of infection?

A. The chemical and bacteriological evidence which has been secured in this case through the experimental and observational data which have been presented justify, in my judgment, the conclusion that the waters of the Illinois River at Grafton show no indication whatever of unpurified sewage from Chicago that has found its way from Chicago to the latter place.

Q. Now, assuming that the only pollution upon the water shed of the Mississippi and its tributaries above the intake of the St. Louis waterworks was that derived from the sanitary district of Chicago, and having in mind a large amount of typhoid fever in Chicago, do you or do you not believe that infectious and dangerous pollution might, under existing conditions find its way into the water supply of the city of St. Louis?

A. On the basis of my belief that the germs of typhoid
fever would not retain their vitality for a sufficient period
10621 so as to be carried by the waters of the Illinois River
from the city of Chicago to St. Louis, and taking into
consideration all of the data, both chemical and bacteriological, which I have any knowledge of, it is my opinion that under the circumstances hypothecated in the foregoing question infectious and dangerous pollution derived from Chicago would not find its way, under existing conditions into the water supply of the city of St. Louis.

Q. Assuming that there was no typhoid fever pollution of the waters upon the water shed of the Mississippi River or its tributaries, above the intake of the St. Louis water works other than that derived from the sanitary district of Chicago, do you or do you not believe that typhoid fever germs from said district are liable to find their way into the water supply of the city of St. Louis, through the intake at the chain of rocks?

A. Under the conditions assumed when the infection of the Illinois River would be confined to the pollution, typhoid pollution, arising from the city of Chicago and taking into consideration the time of flow and the vitality of the typhoid organism in the waters of such river, I do not believe that the ty-
10622 phoid organisms deposited in the waters of the Illinois River would find their way by the way of the Illinois River to the water supply of the city of St. Louis through the intake at the chain of rocks, for the reasons which have been amplified in the previous answers.

Q. Professor Sedgwick, in answer to the question just propounded to you, answered "I believe that they are liable to find their way into the intake," and when asked why, answered "for the reason that typhoid fever having been frequently very abundant in the city of Chicago, I must start with the assumption that a very large number of typhoid germs find their way into the sewage of the city, pass through the sewers and on into the drainage canal, and subject to local conditions may, in diminishing numbers, pass out of the Illinois River, mingle with the waters of the Mississippi River, pass over to the other side and find their way into the intake at the chain of rocks." Do you know of any evidence, based upon any analysis experiments or otherwise that justifies the assumption that typhoid fever germs will pass from the sewers of Chicago into the drainage canal, in diminishing numbers, out of the Illinois River
10623 into the Mississippi and find their way to the intake tower at the chain of rocks?

Mr. Jeffries: I move to strike out the answer by Professor Sedgwick detailed in the question, and the question put to Professor Sedgwick and all of this question down to that portion which calls for the opinion of this witness, for the reason that the same is incompetent and irrelevant and not a necessary part of the question just propounded, and I move to strike out the whole question for the reason that it has already been answered, and this witness has given his opinion as to the possibility of typhoid fever organisms passing from Chicago to the city of St. Louis, which opinion, I suppose, is based upon all of the scientific knowledge which this witness possesses, and the question now propounded simply calls for the repetition to what the witness has already stated.

A. Taking into consideration the time involved in the flow of water from Chicago to St. Louis, and in view of the evidence which I have previously presented in combination with others that the typhoid organism is incapable of retaining its vitality for the period of time assumed in the foregoing question, I would say that I know of no evidence based upon any analysis, experiments or otherwise that would justify the assumption that typhoid organisms deposited in the Chicago drainage canal will pass by way of the Illinois River into the Mississippi
10624 River and find their way into the water supply of the city of St. Louis at the intake tower at the chain of rocks.

Q. Assuming that an epidemic of Asiatic cholera should occur in the city of Chicago, is it possible that the germs of that disease might find their way into the intake tower at the St. Louis water works from the city of Chicago?

A. In view of the fact that all of the evidence, both analytical and otherwise, indicates that the organism capable of producing Asiatic cholera is more sensitive to the influence of external environments than the organisms of typhoid fever, and from the conclusions which have been presented with reference to the vitality of the typhoid organism and their inability to live for a period of time which would be covered by the flow assumed in the question, I should say that it is impossible for the organisms of Asiatic cholera, should they exist in the city of Chicago, to be discharged into the drainage canal and then to find their way down that stream and into the intake tower of the St. Louis water works, at the chain of rocks.

Q. Considering your personal knowledge as an expert of typhoid fever conditions in the sanitary district of Chicago, and existing conditions in said District as to sewers and the outfalls thereof and the amount of sewage under all the existing conditions of the Desplaines, Illinois, Mississippi and
10625 Missouri Rivers, under all conditions existing on the water sheds of said streams and the tributaries thereof

and all existing conditions as to the water supply of the city of St. Louis and the general sanitary conditions existing in the city of St. Louis, would you or not beyond a reasonable doubt attribute the principal portion of the increase of typhoid fever in St. Louis, assuming there has been an increase in St. Louis since the opening of the drainage canal, to the infected sewage of the sanitary district of Chicago?

A. Taking into consideration the knowledge which I possess with reference to the conditions under which the typhoid organisms would be capable of living when deposited in the waters of the streams mentioned in the foregoing question, and taking into consideration the fact that other conditions exist which are necessary to consider in considering the question of typhoid fever in the city of St. Louis, it is my belief that I would not consider, beyond a reasonable doubt, the typhoid death rates as occurring in the city of St. Louis (assuming that there has been such an increase since the opening of the drainage canal) to any influence which might arise from the introduction
10626 of the sewage of the sanitary district of Chicago into the Illinois River and which would find its way down the channel of the Illinois River to St. Louis.

Q. I will get you to state whether or not in your opinion the liability to contract typhoid fever or other water borne diseases on the part of the inhabitants of Missouri, using the Mississippi River water for drinking purposes below the mouth of the Illinois River, by reason of sewage from the drainage canal infecting the water of the Illinois River is constant, immediate and continuous under all existing conditions upon the Mississippi, the Desplaines, the Illinois, the Missouri Rivers and the tributaries of said streams under all existing conditions upon the water sheds of said rivers and the tributaries thereof and the drainage canal of the sanitary district of Chicago?

A. In view of the facts which have been testified to in answer to the foregoing questions relative to the viability of the typhoid organisms and the conditions which would obtain where typhoid organisms are discharged into the drainage canal and the water flows from Chicago to St. Louis, and taking into consideration all other facts which bear upon the conditions of the question as stated, it is my opinion that the liability of
10627 the inhabitants of the State of Missouri using the Missis-

sippi River water for drinking purposes, below the mouth of the Illinois River, to contract typhoid fever or other water borne diseases is not constant, immediate or continuous, under all existing conditions on the Mississippi, the Desplaines, the Illinois and the Missouri Rivers and the tributaries of said streams under all existing conditions on the water shed of these rivers and the drainage canal of the sanitary district of Chicago.

Q. Professor Sedgwick in answer to a question among other things answered "the mere presence of pollution, I mean by that disinfected sewage, that is supposing Chicago reduced her typhoid death rate and would still put her sewage down there, that sewage as affecting the longevity or growth of germs that get in from Peoria or elsewhere would be an added menace to cities with water supply, even if she did not send typhoid fever germs down, sending the filth alone down is serious." I will ask you what is your opinion, based upon your experience as a bacteriologist as to whether the sewage from Chicago favors the longevity or growth of germs from Peoria or anywhere else, emptying their sewage into the Illinois River?

10628 A. It is my opinion that the deposition of sewage of Chicago into the drainage canal does not increase the longevity of the typhoid organism deposited therein, but on the contrary is a potent factor, toward the more rapid destruction of the vitality of the typhoid organism than would be the case if such sewage was not so deposited.

Q. Does the presence of sewage in water add to the longevity or growth of pathogenic germs?

A. When sewage is added to the water in an unsterilized condition such as would exist when normally deposited in drainage canals, the addition of such sewage does not increase the longevity of the typhoid organism, but on the other hand is a distinct factor in the early death of the typhoid organism.

Q. Assuming that the population of the sanitary district is increased to 5,000,000 of people and that the flow through the drainage canal reaches 1,000,000 cubic feet per minute, what in your opinion would be the effect on the water of the Illinois River at its mouth as compared with the water at that point as found prior to 1900?

A. In view of the fact that under the conditions which
10629 now exist and have existed for the period of the last
three years, it is my opinion that the typhoid organism would have been destroyed in a period of time which would comprise only a small portion of the time necessary for water to pass from Chicago to the mouth of the Illinois River, and assuming the increase in population which must also assume an increase in amount of sewage not containing the typhoid organism which would be deposited in the waters of the drainage canal, and taking into consideration the effect which would be produced by such an increase and the influence of conditions as would exist on the basis of the assumption made, it is my opinion that the addition of the sewage coming from the number of people mentioned, discharged into the amount of water mentioned would not materially alter the conditions which would exist in the waters of the Illinois River at its mouth, so far as these conditions had any effect upon the elimination of those elements in sewage which are of importance in sanitary matters. The addition of this increased amount of sewage would probably alter the amount of soluble substances which would appear in the waters of the Illinois River at its mouth, but these would have no effect upon the sanitary condition of such waters.

Q. Assume that the Chicago sewage from 1,500,000 peo-
10630 ple living in the sanitary district and city of Chicago
should be discharged into the Chicago drainage canal and through the canal into the Desplaines and into the Illinois River, Chicago being situated 357 miles from the St. Louis intake tower, and assuming that a typhoid fever epidemic of extraordinary proportions or a cholera epidemic of extraordinary proportions should become prevalent among the residents of the sanitary district of Chicago at a time when the sewage from said district is being so discharged into the canal, what immediate and impending danger would exist, and what effect would it have upon the people of St. Louis and those people living on the Missouri side of the Mississippi river below Grafton, who use the waters of the Mississippi river for drinking purposes?

A. Taking into consideration the conditions which are operative in nature that lead to the destruction of the typhoid organism when brought in contact with water and sewage organ-

isms such as would exist under the conditions, hypothecated, and also considering the greater sensitivity of cholera to the influences of these conditions in comparison with what happens to the typhoid organism when exposed to such conditions and taking into consideration the distance involved, 357 miles from Chicago to St. Louis, and the time which is necessary for
10631 the sewage containing typhoid or cholera organisms to pass from Chicago to the St. Louis intake, it is my opinion then that no immediate and impending danger would exist to the people of St. Louis or those living on the Missouri side of the Mississippi River below Grafton, and therefore that no effect would be produced upon such people who would use the water of the Mississippi River for drinking purposes.

Q. From your personal knowledge of the Illinois River and your knowledge as a sanitary expert, together with all chemical and bacterial knowledge derived from every source, what is your opinion as to whether the sewage from the city of Chicago, passing through the drainage canal into the Illinois River at different seasons of the year and at different stages of water would be a danger and menace to the inhabitants of the State of Missouri and the citizens of the city of St. Louis, using the water of the Mississippi River for drinking and domestic purposes?

Mr. Jeffries: I object to that as a repetition.

A. Taking into consideration the chemical and bacterial knowledge which has been derived from actual experiment and also all knowledge which I possess with reference to the conditions which would obtain when the sewage of Chicago was
10632 placed in the drainage canal, and taking into consideration the possible variation which would exist at different seasons of the year and the influence which different stages of water would exert upon the vitality of disease organisms which might be present in such sewage, it is my opinion that the introduction of such sewage into the Illinois River would not be a danger and a menace to the inhabitants of the State of Missouri and the citizens of the City of St. Louis who might use the waters of the Mississippi River at the intake tower, chain of rocks.

Q. From all your knowledge of conditions that obtain in and along the Illinois River, what is your opinion as a sanitary expert as to whether deleterious substances, infected matter or pathogenic germs which come from the drainage canal from the sewers of Chicago would reach as far down the Illinois River as the City of Peoria?

A. From the analytical data which has been presented, it is shown that the addition of the sewage of Chicago to the waters of the drainage canal results in such a degree of purification that I do not think that deleterious substances or infectious matters capable of producing disease would be found in the waters of the Illinois River at the city of Peoria, which were derived from the sewers of the city of Chicago.

10633 Q. Would any of these substances in a dangerous state reach the intake tower of the St. Louis water works at the chain of rocks in your opinion?

Mr. Jeffries: Objected to as immaterial and a repetition.

A. For the reasons cited in the foregoing answer and for the reason that the time of flow from Chicago to St. Louis would be greater than from Chicago to Peoria, it is my opinion that none of these substances in the sewage of Chicago would reach the city of St. Louis in a dangerous state.

Q. As a sanitary expert do you consider the sewage of Chicago reaching the drainage canal and the Illinois River, which in turn empties into the Mississippi River a menace and a danger to the inhabitants of the State of Missouri and the citizens of the City of St. Louis, taking their water supply from the Mississippi River.

Mr. Jeffries: Objected to as a repetition.

A. On the basis of the data previously presented it is my opinion that the deposition of the sewage in the drainage canal is not a menace and a danger to the inhabitants of the state of Missouri and the citizens of the city of Et. Louis who take their water supply from the Mississippi River at the intake tower.

10634 Q. What is your opinion as a sanitary expert as to whether the germ of the typhoid fever could lie in the sediment of the drainage canal or the Illinois River for a period of from one to three years?

A. I know of no experiments or data which warrant the conclusion that the typhoid organism would be capable ot retaining its vitality in the bed of a stream for this period. On the contrary, I do not consider that it would be possible for the organism to live for any such period of time.

Q. What is your opinion as to whether the typhoid bacillus, deposited on the bottom of the Illinois River could remain there for a period of upwards of five years and then be stirred up by the action of the waves, winds, steamboats or by other means and continue its journey down to St. Louis in a virile state and be a cause of danger to the inhabitants of the state of Missouri or to the citizens of the city of St. Louis using the water of the Mississippi River, at the city of St. Louis, for drinking and domestic purposes?

A. It is my opinion that the typhoid organism would not be able to retain its vitality for the period mentioned, and therefore could not continue its journey in a virile state and be a source of danger to the inhabitants of the state of Missouri and the citizens of St. Louis who used Mississippi River
10635 water for drinking and domestic purposes.

Q. Will you state as a sanitary expert, basing your opinion upon all the information you possess in this ,case whether the water supply of the city of St. Louis is contaminated, polluted or injured by the sewage of Chicago entering the drainage canal and from thence into the Illinois River?

A. For reasons which have been previously given and amplified it is my opinion that the sewage of the city of Chicago would not be a means of contaminating, polluting or injuring the water supply of the city of St. Louis.

Q. Assuming that five dams, one at Marseilles, one at Henry, one at Copperas Creek, one at La Grange and one at Kampsville, existed in the Illinois River, backing the water up stream for a considerable distance; also there is a lake known as Joliet, a lake above Peoria known as Lake Peoria and many small lakes lying along the Illinois River, receiving their water supply from the Illinois River, what effect would these dams and lakes have as sedimentation basins and also what effect would they have in the elimination and purification of polluted and infected matter, coming into the Illinois River from the different towns sewering into said river?

A. Taking into consideration the well recognized fact

10636 that where a current of a stream is retarded in its rate of flow by an expansion of the cross section of said stream, which condition causes the sedimentation of any suspended matter which may be present in the waters of such stream, it is my opinion that the presence of such expanded portions of the Illinois River would act in a material way in aiding the sedimentation which would occur in the waters of that stream and that such sedimentation would result in the elimination of a large proportion of the total bacterial life, including any disease organisms, if such should happen to be present, that might be present in such waters.

Q. Assume that as the volume of water passing through the drainage canal is increased, the dams at Henry, Copperas Creek, LaGrange and Kampsville, should be removed, would the removal of these dams affect the purification of the sewage of Chicago to such an extent as to be manifest at Grafton?

A. In view of the fact that the sewage of the city of Chicago is practically purified before it reaches a point upon the river where the removal of these germs would exert any appreciable effect upon the conditions which obtain in that river it is my opinion that the removal of these dams, as indicated in the foregoing question, would exert no effect upon the
10637 condition of the waters of the Illinois River at its mouth
at Grafton, so far as the sewage of the city of Chicago is concerned.

Q. Will you state as an expert sanitarian, from all sources of knowledge that you possess, whether the water of the Mississippi River at the chain of rocks was, prior to January, 1900, a safe and potable drinking water, fit for domestic and drinking purposes, in its raw state, after passing through the settling basins?

Mr. Jeffries: Objected to as immaterial.

A. Taking into consideration the fact that surface waters which drain water sheds more or less densely populated, are in a general sense waters which are no doubt more or less incidentally connected with an increased incidence of typhoid fever and other water borne diseases, and taking into consideration the fact which would exist in the question as asked where a water supply might be polluted with dangerous pollution under the conditions which would prevail where the time of flow would not permit of the purification of such water from the sewage which was so discharged, and taking into consideration 10638 the conditions which obtained in the city of St. Louis prior to the year 1900, it is my opinion that such water, furnished under the conditions asked for, is not to be regarded as a thoroughly safe and potable water supply, suitable for all domestic and drinking purposes.

Q. Was the Missouri River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900?

A. The Missouri River draining a large water shed on which there is a large number of people, and into which there is discharged the sewage of such people, would be regarded as a stream which was very liable to carry pollution for varying distances, and it is my opinion that such a stream is not to be regarded as a perfectly safe supply for drinking purposes.

Q. Was the Illinois River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal, in January, 1900?

A. For the reasons given in the foregoing answer I should also state that the Illinois river was not to be regarded as a safe supply.

Mr. Jeffries: I move to strike out the last three preceding questions and answers as immaterial.

10639 Q. Has the sanitary conditions of the waters of the Illinois River at Grafton been benefited or damaged by the opening of the drainage canal?

A. I do not consider that the waters of the Illinois River at Grafton should be looked upon as a perfectly safe supply, regardless of the possible changes which have been made by the opening of the drainage canal.

Q. Is the water of the Mississippi and Missouri Rivers, excluding the waters of the Illinois, a safe and suitable water for domestic and drinking purposes, to be used by the citizens of St. Louis in its raw state or treated as now by the City of St. Louis with settling basins, since January, 1900?

Mr. Jeffries: Objected to as immaterial.

A. I consider that the use of the waters of any drainage system, such as obtained in the Mississippi and Missouri Rivers, is not to be considered as a safe and suitable supply for drinking purposes, as it exists under the conditions which obtain in the foregoing question.

Q. Taking into consideration all the knowledge which you possess in regard to the chemical bacteriological and physical condition of the waters of the Illinois river and its tributaries, and the river itself, the different towns sewering into the Illinois river and its tributaries, the population upon the water
10640 sheds of the Illinois river, both the rural and the urban, the stages of the river under all conditions and during all seasons, what is your opinion as to the effect of flowing the sewage from Chicago through the drainage canal into the Desplaines and Illinois rivers, upon the inhabitants of the State of Missouri, using the water of the Mississippi river for drinking and domestic purposes?

A. Taking into consideration the conditions hypothecated, that the sewage of Chicago is discharged in the drainage canal at such a distance from the State of Missouri that dangerous pollution coming from the sewage of the city of Chicago, so far as that pollution itself is concerned, would be deprived of its dangerous properties during the period of flow which is necessary for the passage of such sewage from the city of Chicago to the State of Missouri, it is my opinion that the sewage of Chicago, discharged into the drainage canal, will have no deleterious effect upon the inhabitants of the State of Missouri using the water of the Mississippi river for drinking purposes.

Q. Assuming all the facts as contained in the foregoing hypothetical question, and in addition from a study of
10641 all the typhoid statistics as they obtain along the water shed of the Missouri, Mississippi and Illinois rivers, and in the City of Chicago and in the City of St. Louis, and assuming that an increase of typhoid fever deaths, as evidenced by the death rate in St. Louis, as disclosed by the board of health reports of the City of St. Louis, and taking into consideration all the knowledge which you possess upon this subject under consideration, what is your opinion as a bacteriologist and sanitarian and epidemiologist as to whether the said increase in typhoid fever in St. Louis, assuming there has been an increase as above indicated, since the opening of the drainage canal can be attributed to the opening of the drainage canal as the direct,

immediate and proximate cause of said increase beyond all reasonable doubt?

A. In view of the fact that the conditions which obtain in the City of St. Louis and the conditions of the watersheds which are immediately adjacent to this city, in view of the fact that the typhoid fever death rate in that city is dependent upon other conditions than those due to the water supply of that city, and may be materially influenced by operation of many other 10642 factors, in view of the conditions which obtain in the Illinois river with reference to the process of purification which would occur in the sewage of Chicago when deposited in the drainage canal, and taking into consideration all the knowledge which I possess with reference to all data which bear directly or indirectly upon the question involved, it is my opinion that the increase in the typhoid deaths, as reported in the City of St. Louis, assuming such increase to be true, which have occurred since the opening of the drainage canal, can not beyond all reasonable doubt be attributed as a direct, immediate and approximate cause for said increase to the opening of that drainage canal.

Adjourned until 2:00 p. m., of same day.

10643 2:00 p. m., Saturday, February 20, 1904. Continuation pursuant to adjournmnet.

Present, the Commissioner and same counsel representing the respective parties.

PROF. H. L. RUSSELL,

resumed the stand for cross-examination, by Mr. Jeffries, and testified as follows:

Q. Are you a practical chemist, Professor?

A. No, sir.

Q. You make no chemical or laboratory experiments?

A. No, sir.

Q. You use it, then, in your work as a sanitarian purely from what you have found to be its import from reading and practice and from your experience in assisting other sanitarians do you not?

A. I use the data which are collected in chemical examinations of water for sanitary purposes as a factor, which together with the bacteriological analysis of the same material is co-ordinated, interpreted together.

Q. Why is it, Professor, that a sanitarian can not pass judgment, reliable judgment, upon the sanitary condition of the water from the chemical and bacteriological observations of that water without taking into consideration the extent and
10644 sources of pollution and population and other natural conditions on the watershed?

A. The chemical examination of the water is entirely an indirect examination. No chemical examination by itself will determine the presence of disease organisms in a water supply. In the development of the subject of sanitary science the chemical methods were first employed and it was necessary where this indirect method of examination was employed for the person who interpreted the findings to take not only the chemical data into consideration but all the data which threw any light on the origin, the nature and conditions of the water. In the bacteriological examination of water supply the attempt may be made to determine the actual presence of disease organisms and if such were found, it would not be necessary to take into consideration the sources of pollution and other conditions mentioned, but if the bacteriological analyses are not made with reference to the direct determination of the presence of pathogenic organisms, but by the indirect method, then the use of these sources in the light of the data collected by both chemical and bacteriological methods are all factors which appertain to the problem in hand.

10645 Q. In passing judgment upon the sanitary condition of a water at a given point is not the number of people residing upon the watershed above this given point one of the prime factors in the determination?

A. I consider that it is possible to arrive at a satisfactory examination of a water supply on the basis of chemical and bacteriological methods without necessarily taking into consideration the matter of population.

Q. In passing judgment upon a sanitary condition of water from a bacteriological standpoint do bacteriologists take into consideration the number of bacterial counts or the character of the counts as shown by the observation?

A. This would depend upon the origin of the water involved in the analyses. In the analyses of certain waters, the determination of the number of organisms present is of minor importance as a general rule. In the determination of the sanitary quality, the qualitative data are regarded as of more value than the quantitative data.

Q. Upon what sources rest, as a rule, the qualitative data found in the sanitary observation of water?

A. Assuming that your question refers to the bacteriological examination, the qualitative data referred to are
10646 secured by determining the absence or presence of organisms which are usually associated with sewage and especially the relative number of those organisms, taking also into consideration the origin of the water as to whether it is water which had been in contact with the upper layers of the soil or is derived from subterranean source.

Q. Is there any graduated rule or formula used by bacteriologists in making these sanitary determinations from a bacteriological standpoint as measured by the population on the watershed above the point in the stream where the water is examined?

A. I know of no such mathematical rule.

Q. Has there been any rule or formula established of a general kind based upon the experience of sanitarians during the past years upon various streams throughout the country by which a basis of determination could be made from the bacterial condition of the water of a given stream as shown by the observation and as compared with previous bacterial observations of streams by sanitarians?

A. It is generally conceded that in surface waters the presence of bacteria belonging to the colon type may be noted on account of the fact that these waters have been brought in contact with the surface of the soil where the opportunities for
10647 the introduction of colon organisms from divers sources may be present and in the determination of the sanitary quality of water of this character, it is therefore especially necessary that emphasis be laid upon the quantitative presence of this type of bacterial life. The water supply containing a large number of colon organisms is therefore one that could be re-

garded by bacteriologists as more or less polluted with sewage at no distant previous date.

Q. Is it not a fact, Professor, that water supplies have been known to have been affected with this disease producing organism that contained small quantities of coli bacilli?

A. I am unable to answer that question unless I know more specifically what you mean by small quantities of colon bacilli and also as to whether the water was of subterranean or surface origin?

Q. Is it not a fact that surface waters, such as lakes and rivers, have been known to have been infected with disease producing organisms which did not contain a sufficient number of colon type to render the water suspicious as shown by the ordinary means of analysis?

A. I do not now recall any cases where under natural conditions the water has been infected with disease pro-
10648 ducing organisms to such an extent as to be able to pro-
duce epidemic disease and where such waters upon examination made at that time failed to reveal the presence of a colon organism in considerable numbers. I can conceive of where an infection was sporadic and discontinuous that the evidence of such infection might not be revealed by bacteriological analysis at some subsequent date and still that water might have previously been the direct cause of epidemic disease.

Q. In your opinion in an examination of the sanitary condition of the water is it necessary to take into consideration the extent of the population residing upon the watershed of the river under examination or form your opinion from the determinations of the bacteriological and chemical analyses regardless of what may be situated upon that watershed, so far as domestic and manufacturing waste is concerned?

A. I think that it would be possible to determine whether a water materially changed from what previous experience had shown to be the case with normal streams which were not infected with sewage or drainage from human beings without taking into consideraton the density of the population on that watershed. The size and area of the watershed and its
10649 nature whether forrested or unforrested and the char-
acter of the soil and numerous other problems which are not directly related with the presence of human life are factors

which are quite as important in determining a matter of this sort as the density of the population itself.

Q. Might not a colon type be found in water unexposed to the excreta or sewage?

A. It might. The colon organism is a normal inhabitant of the intestinal tract of higher mammals and other animal forms, and therefore its mere presence in surface water—this fact taken simply by itself—can not be regarded as direct evidence that its presence had originated from human excreta.

Q. Is it not a fact, Professor, that in the sanitary observation of water, sanitarians become more interested in determining the presence of pathogenic bacteria or organisms rather than in the quantitative presence of those organisms?

A. The ordinary sanitary examination from the bacteriological point of view alone does not attempt to determine the direct presence or absence of specific pathogenic bacteria.

Q. What then is the object of the sanitarian in making the observations of this character?

10650 A. Because of the intimate relation under existing natural conditions which exist between pathogenic organisms capable of producing disease and certain well known bacteria which do not belong to the distinctive pathogenic class, but which can be very much more readily detected in water. The difficulties which confront the bacteriologist in the isolation of pathogenic bacteria are such that under natural conditions the chances of his finding the organism would be exceedingly remote.

Q. The sanitarian then reasons that because of the presence of that class or character of organisms which belong to certain pathogenic bacteria is associated with them that they are present?

A. The methods followed by the bacteriologist are primarily indirect, although not to the degree that the method of the chemist is, and positive findings of this indirect method afford him presumptive evidence which serves as a further basis for investigation and may be supplemented by direct examination for the presence of pathogenic organisms. This provided that the conditions of the test are such as to indicate the probable presence of those organisms at any given time.

Q. So that after all these determinations and observations are made with a view of determining the possible pres-

10651 ence of pathogenic bacteria rather than the extent or quantity of such pathogenic organisms, if present?

A. The conditions to which pathogenic bacteria are subjected in nature are such as to produce a rapid loss in vitality of those organisms and consequently a water may be of such a character as to result in a production of disease and if the examinations are not made in large numbers at that particular time the organisms of a pathogenic character may lose their vitality to such an extent that the determination of their presence and not the number of the pathogenic organisms present may be fairly considered as indicating the probable nature of that water as to the liability of producing epidemic disease.

Q. State whether or not the typhoid bacilli is customarily found by observers in water supplies?

A. It is not. The attempt is not often made to search for the pathogenic organism directly because of the difficulty of the case.

Q. Now, what difficulties are most likely to arise and exist in making these determinations for the pathogenic bacteria in water supplies?

10652 A. When we take into consideration the fact under natural conditions which would obtain in any community that the organism producing typhoid fever requires for its period of incubation a period of time ranging from several days to several weeks; that after the symptoms of the disease appear in the first persons infected, that another period of several days elapses before the excreta of the typhoid patient actually contains typhoid organisms, and that moreover the water supply is rarely brought under suspicion until after a number of typhoid cases have appeared in any given community, that the period of time which may have elapsed between the original infection of the water which would be capable of starting an epidemic of this disease and the time which would elapse before such waters are ordinarily subjected to examination is usually so long that the organism might have entirely disappeared from the water or be reduced to such small numbers that its determinations is rendered very much more difficult it is evident that the difficulties which attend such direct examination are numerous.

Q. Do you in your observations make a practice of looking for the typhoid bacillus and such other pathogenic bacteria in suspected waters?

A. In my routine analytical work the practice is never 10653 followed of making a direct examination of such waters as are ordinarily examined for the purpose of detecting the presence or absence of typhoid organism.

Q. Is there any rule or formula in the science of bacteriology or in sanitary science which measures the life of all classes and kinds of typhoid bacilli virility in sterilized water?

A. The conditions which obtain when we attempt to determine the vitality of any living organism are such that I deem it impossible to formulate with mathematical exactness the period of time which the vitality of any organism could be determined.

Q. Do you deem it unreasonable to undertake the formulation of a rule or system by which the life of the typhoid germ or organism may be measured in running water, in river water, in sewage, in highly polluted water, in sewage polluted water, in sediment, in soil, in moist soil, under all conditions of nature and if so, please state why in your judgment such formula is impossible

A. The conditions to which the typhoid organism would be subjected under the variety of conditions as outlined in the foregoing question, are subject to the influence of so many factors, the effects of which are not directly comparable 10654 and which must be taken into consideration in the different cases involved that I do not consider that one can say with mathematical accuracy just how long it will take for the typhoid organism to be destroyed in those waters, but that in giving an opinion in regard to a matter of this sort one must base his judgment upon the fact that there is some variation to be observed in the influence of these different factors and one could place this limit at such a point as would in his judgment be a safe limit for the destruction of the organism concerned under the variety of conditions which were under consideration.

Q. The conditions of moisture in the soil, the character of the sediment, the character and extent of pollution, the extent of dilution are so variable no rule or formula could be adopted by which the life of the typhoid germ under these various conditions might be accurately observed without taking into consideration the degree of variation that exists in the longevity of the various germs themselves. That is, the extent of their virility, their hardiness and robustness as compared with each other?

A. I do not consider that the data given with reference to the longevity of the organism could be expressed in
10655 terms with mathematical accuracy, and if it were so expressed it would be necessary to take into consideration the effect of these factors mentioned, that the typhoid organism is subject to the influence of these variable factors, and that these might change the rate of destruction and in setting such a limit it must be placed at such a point as in the judgment of the investigator will be sufficient to permit of the operation of all of these factors referred to, and effect the destruction of all organisms of the class concerned.

Q. So that the organisms of typhoid fever like everything else in nature, depend so far as longevity is concerned upon the environments surrounding each particular germ, together with the particular character of the germ itself?

A. The factors which are of import in the destruction of any organism are those which are inherent to the organism itself and also those which relate to the external environment. These may be varied in such a way as to accentuate the rapidity of the process or not.

Q. So that in accordance with the inherent vital qualities of and the external environment of each particular germ the longevity of that germ is measured?

A. So far as any one particular germ is concerned that is true. But it should further be said that experiments which are made under conditions where divers strains of organisms are employed that the validity of the conclusions drawn from
10656 such experiments is very much increased where the experimental conditions are different in each case owing to the fact that more than one strain of the organism is employed.

Q. And thus differences may result from these unobservable differences in the observations brought about because of the extreme delicacy of the observation?

A. The experience of the operator in dealing with matters of this sort is a factor which is of very material significance in interpreting the data of such experiments.

Q. How long have the typhoid bacilli been known to live in sterilized water?

A. Experiments made with typhoid bacilli inoculated into sterilized water have demonstrated the ability of this organism to live for a period measured by a number of months and in some instances upwards of 100 days. The results obtained are widely discordant with respect to the exact time.

Q. That also depends, does it not, upon the inherent quality of the germ itself?

A. In case of tests made on sterilized water the variations reported are undoubtedly due to the effect which is produced
by both sides of variables; first, those which are inherent
10657 to the constitution of the organism in question; second,
those which are produced by the variation in the environments?

Q. This particular germ lives longer in sterilized water than under any other condition in nature other than that of the laboratory experiments or in the human system, does it not?

A. I am uncertain as to what is meant by laboratory experiments, but interpreting that question to be the inoculation of typhoid organisms in culture medium kept in laboratory for stock purposes, stock cultures, I should say that the vitality of the typhoid organism in boiled water but not necessarily sterile water, is marked by a period of duration, longer than exists under natural conditions.

Q. Would it live as long under such conditions as in the soil, or in privy vaults?

A. Interpreting your quesion to refer to the viability of an organism in boiled waters, I am of the opinion that the vitality of the organism might be retained in the water sterilized by boiling, a longer time than would be the case if the organism
10658 was exposed in contact with human dejecta, in a moist
condition.

Q. You stated, I believe, previously, that the typhoid bacilli was a very difficult matter to observe, in the bacteriological examinations of water?

A. I stated it was very difficult to determine its actual presence.

Q. Is it not a fact that it is a difficult matter to find it, even in sewage when the observer knows it had been deposited recently, or discharged, that is, that the typhoid bacilli had recently been discharged into the sewage?

A. When examined under the conditions which would exist in nature, where the typhoid organism would be brought into contact with myriads of sewage bacteria, which themselves are capable of extensive multiplication, it would be a difficult matter to determine the absence of all typhoid organisms, but it is possible by means of the elective media which are now employed in the best laboratories, for the typhoid organism to be differentiated from human feces, and diluted organic matter rich in materials of sewage matter.

10659 Q. Is it not a fact that competent observers have found the typhoid organism to live in sewage for a period of from five to seven days, in the laboratorial experiments?

A. Interpreting your question to refer to the vitality of the typhoid organism when subjected to sewage under perfect natural conditions and normal conditions, I should say that experiments which give such a period of vitality to the typhoid organism, must be tested in the light of the newer methods of differentiation which have been introduced since the agglutining, or Widal test has been devised, and which is now regarded as the most crucial single characteristic which we possess for the differentiating of the typhoid organism from related bacteria.

Q. Has it not been so proven?

A. I do not recall at the moment, any experiments which have been made on the typhoid organism, on raw sewage, 10660 where the identification of the organism has been made on the basis of all the methods which are now employed for the differentiation of the organism from related forms, and in which the vitality of the organism so exposed under natural, normal conditions, was retained for a period as indicated in the foregoing question.

Q. The life of the germ in sewage would depend largely upon the extent of the concentration of the sewage material?

A. It is my opinion that the concentration would not be operative beyond a certain point. That the difference between the sewage containing say, 10 per cent. of solid excreta, and say 20 or 25 per cent. of solid excreta, would not be such as to materially alter the rate of loss of vitality.

Q. These percentages which you have just stated, are within the limits of ordinary sewage?

A. No, those percentages contain more solid matter than are found in normal sewage, but by the previous answer I mean that the rate of death would not be affected, if there was a sufficient amount of the products of other organisms present 10661 in the sewage organisms themselves to accomplish the destruction of the typhoid organism in a period of time.

Q. And as the extent of the dilution in a measure localizes the longevity of the germ?

A. When the degree of concentration is at such a point as to just be able to destroy the typhoid organism in a given period of time, manifestly the dilution of that degree of sewage concentration with water which would reduce the amount of prejudicial substances, would permit of the retention of the vitality of the typhoid organism for a long period of time.

Q. State, Professor, whether or not in your opinion the typhoid fever germs lived longer in the waters of the Chicago river prior to the opening of the Drainage Canal than they will now live in the waters of that river, in the Canal?

A. My opinion is that the changes that have been produced in the Chicago river through the opening of the Drainage Canal, are not such as will greatly modify the death rate of the typhoid organism when exposed under these two conditions.

10662 This opinion is based upon my belief that in either instance the degree of concentration in the water of bacterial by-products, and the presence of saprophytic bacteria themselves would be sufficient to cause an early death of typhoid organisms placed in this water.

Q. If the typhoid organisms rapidly died out, in the waters of the Chicago river, prior to the opening of the Drainage Canal, what effect would the discharge of that water into Lake Michigan, have upon the prevalence of typhoid fever in the City of Chicago, taking its water supply from Lake Michigan?

A. As I understand the conditions which have prevailed in reference to the pollution of the waters of Lake Michigan by sewage of the City of Chicago, a certain proportion of the sewage of Chicago has been discharged into the waters of Lake Michigan, without remaining in the waters of the Chicago river, and such sewage would have found its way into the pure waters of the Lake within a sufficient period of time so that it is probable that the vitality of the typhoid organism would not have been lost during this period, and hence it was possible for the conditions which obtained in nature to serve 10663 as an agent for the production of disease in Chicago even though diluted with the lake water.

Q. It is your opinion, then, is it, that none of the typhoid germs which passed into the Chicago river prior to the opening of the canal, found their way into Lake Michigan, and from thence into the water supply of the City of Chicago?

10664 A. The answer to the preceding question did not state that no typhoid bacteria did find their way through the water of the Chicago river and so into the waters of Lake Michigan, but it is my opinion that the major part of the infection arose from sources where the typhoid organism was not exposed to conditions in sewage for long periods of time.

Q. It is your opinion, then, that the greater part of the typhoid organisms which produced fever in Chicago entered the lake from some source other than the Chicago river?

A. It is quite conceivable that a considerable portion of the organisms which found their way into Lake Michigan may have been carried there by way of the Chicago river, but it is my belief that at such times as the river was flushed by heavy rains which would sweep the sewage out in the lake more rapidly than otherwise would have been the case, that this has been assigned as a potent cause for the incidence of typhoid fever in this city.

10665 Q. Would that not in your judgment cause spasmodic waves of typhoid fever to take place in the City of Chicago?

A. Interpreting your question to mean spasmodic waves of short duration, I should say not necessarily the case.

Q. How many typhoid epidemics have you personally examined, Professor?

A. Interpreting your question to refer to epidemics where I have had anything to do with the analysis of waters at or soon after the time the epidemic occurred, I have examined the conditions which prevailed at the city of Ashland, city of Baraboo, city of West Superior, at Marinette, and Menominee, Michigan.

Q. Were each of these epidemics caused by a typhoid water supply?

A. Each of the epidemics produced in the cities mentioned was caused by impure water supplies.

Q. Can you give the source of infection in each of the three cases, the West Superior, Baraboo and Marionette?

A. In the case at Baraboo, the water supply is drawn from a series of springs and deep wells, situated below the town. The power house for the pumping of the water is situated on the banks of the Baraboo river and for power purposes the 10666 water from the Baraboo river was employed, being derived from the main stream at a point below the town and below the outfalls of the sewers of the city. The water, used in this race, for purposes of pumping the water from the wells by the aid of a water pump, was in a highly polluted condition, owing to the fact that the sewers of the city entered immediately above. The intake pipe from the wells passed from the wells to the pump house directly through this race of highly polluted water, and it was found upon examination that in this intake pipe consisting of short pieces of iron pipe, five leaks were present, so that when the water was pumped by aid of a steam pump, which had a much higher suctional action than the water pump which was used for reserve purposes, the water was drawn in through these leaks from the race into the intake pipe. This intermittent introduction of large quantities of polluted water that would naturally occur when the slower acting water pump was employed was discovered by charting the case rate of the disease as it existed in the city and noting the striking relation which was evident between the use of this steam pump and the wave like outbursts of the fever in the city. Examination of the waters at that time revealed the presence of 10667 the polluted condition and the full examination of the conditions mentioned occurred in my judgment from the pollution of this supply which caused an epidemic of about 150 cases of typhoid fever in a period of six weeks, and in a town of about 5500 population.

The epidemic at Ashland was produced in this way: The sewers of the city of Ashland are discharged into Chequamegon Bay, a shallow arm of Lake Superior. To protect the harbor the government built a breakwater about a half a mile from shore. The current from the lake sets into this bay, passes around the north and the west shore of the bay, receives the sewage of the city of Ashland and then passes out around the two ends of this breakwater. When the water supply for the city of Ashland was introduced, the intake pipe was run out into the bay water and stopped on the land side of the break water, that is between the break water and the land. The result was that with the increasing amount of pollution discharged into the bay, and the flowing of the current around and consequently out past the intake pipe, that the diluted sewage of the city was brought back in the water mains of the town. This resulted in the production of an extensive epidemic of upwards of about 200 cases in a town of 10,000 or 12,000 inhabitants.

Q. How far was the intake of the water supply at Ashland situated from the mouth of the sewer?

A. About three quarters of a mile I should say.

10668 Q. Out in the lake?

A. Out in the lake with the current at times passing directly from these outfalls towards the mouth of the intake pipe.

Q. How deep was the lake at that point?

A. The bay is a shallow bay at this point, varying perhaps from 10 to 15 feet in depth.

The Marinette and Menominee epidemics occurred simultaneously, and typhoid fever had been present there in much larger than usual proportions for several years. The sewers of the city of Marinette are discharged into the Menominee river, and one of the largest sewers of the city of Menominee is discharged into Green Bay. The Menominee river empties into Green Bay. The intake pipe of the water supply is off shore at a distance of about 2,000 feet. The analytical data collected at the time of this epidemic showed that often the water at the intake pipe was normal Lake Michigan water, and at other times, depending upon wind action, would indicate a polluted condition. The presumption is very strong in favor of the view that the sewage of this city was carried out for the distance of 2,000 feet, at times found its way past the intake pipe and was pumped up into the water mains.

Q. Going back to Ashland, state whether or not the city

10669 of Ashland is situated upon an abrupt decline or on a level plain?

A. It is not on a hill slope. I should say that the elevation of the center part of the town ranged from 10 to 30 feet above the lowest.

Q. And that is true with this last place?

A. I have not examined personally the conditions at Menominee and Marinette.

Q. All of these epidemics, however, were caused by sewage pollution, that is each of these that you have just explained, or sewage infection?

A. I should so consider it, yes, sir.

Q. Professor, in the joint and concurrent investigations or observations which were made by yourself, Professor Jordan and Professor Zeit, did you each use strains of culture from the same source?

A. Professor Jordan and myself, I think, used the identical same strains. Professor Zeit, I believe, employed, in addition to the strains which Professor Jordan and myself used, one other.

Q. The strains denominated "X," "Y" and "Z" by 10670 you in your direct examination and as shown on the table which you read in evidence represent cultures from the same strains as those used by Professor Jordan in his examinations, as I understand it?

A. And denominated by him "X," "Y" and "Z."

Q. And denomiated by him "X," "Y" and "Z?"

A. Yes, sir.

Q. In point of inherent vitality, can you from the table which you read in evidence, and your observations made of these three strains, state whether or not they were of different inherent vitality?

A. The analytical data would not enable me to draw such a conclusion.

Q. Why not, Professor?

A. To have determined this point it would have been necessary to have made the observations at very much more frequent intervals than they were made.

Q. Did you make or attempt to make any such determinations from these strains?

A. I did not.

Q. Is it not a fact that the addition of the total number of typhoid seedings deposited in the samples of water used 10671 by you had a tendency to decrease the life of those particular organisms over what the life of any one of those organisms would have been had it been deposited alone in the samples of water used in the determination?

A. It is a well recognized fact by bacteriologists that variation in the amount of seeding does exert a difference in the rate at which loss of vitality occurs, and that the heavier the seeding from a given volume of water the longer will be the vitality of the organisms in that water rather than shorter, so I would conclude from this that so far as this effect was concerned the increase of typhoid seeding would if it had an effect, increase the vitality of the organism over what would have been the case with very light seedings.

Q. How deep under the surface of the water were these parchment sacs placed or suspended?

A. To a depth of about 6 to 12 inches, just sufficient to prevent excessive wave action. We lost a number of the sacs when exposed on the surface, because of breaking from the waves.

Q. The life of the germ as found from your experiments ranged from one to 9 days in the water of the Illinois river, does it not, at Averyville?

10672 A. I do not consider that the life of the typhoid organism as illustrated by the experiment cited, does range for a range of one to nine days.

Q. What significance do you attach to the presence of the organism on the ninth day in sac number 15 of the "Z" strain?

A. Taking all of the data which is incorporated in the table at hand, and taking into consideration the fact that in 141 tests made on the first three days the typhoid organism was found in 69 cases, and further taking into consideration the fact that in 318 analyses conducted subsequent to the third day only one organism was found which was proven to be typhoid in character, and further taking into consideration the fact that the results of the experiment are so overwhelmingly concordant with the exception of this single case, it is my opinion that the conclusion which is to be drawn from this experiment, taken as a whole, warrants the conclusion that typhoid organisms exposed under the conditions of the experiment would be incapable of retaining their vitality in the waters of the Illinois River at Averyville for a period which exceeds that reported in my direct evidence.

10673 Q. Is it not a fact, Professor that of strain Z, sac number 15, as shown on your table, you made an examination of the contents of that sac on five separate days, towit: the first, the second, the fifth, the ninth and the twelfth, and that of those five examinations you found the typhoid bacilli present in the first, the second, and the ninth days?

A. That is true.

Q. Have you any reason to believe that you would not have found it present on the third and fourth days?

A. It is highly probable that if an examination of that particular sac had been made upon the third day after immersion, that the typhoid organism would have been discovered in such an examination.

Q. And how about the fourth day?

A. Taking into consideration all of the analytical evidence which is shown in the accompanying table, where the conditions are all as nearly uniform as can be secured, under the conditions of the experiment, and further taking into consideration the fact that out of twelve colonies examined on the fifth day, none of these proved to be typhoid, or of the 14 examined on the tenth day, 13 of which proved not to be typhoid, and of two examined on the twelfth day, neither of which proved to
10674 be typhoid I believe that I am justified in the conclusion
that if an examination had been made upon the fourth day, the results which would have been obtained would have been in practical accord with the results which are shown as having been obtained in those cultures which were made with the cultures "X" and "Y," when the examination was performed upon the fourth day and where in no case in 41 examinations was the typhoid fever organism found in any instance.

Q. When you speak of 41 examinations, you mean 41 colonies picked off or fished off the plate?

A. I do.

Q. How many platings did you make of each particular sample of water analyzed or observed on each day?

A. In testing the number of organisms found in the tube it was customary to make at least three plates from each sample, and from an inspection of these samples select those organisms which showed presumptive typhoid appearances.

Q. What was the quantity of water plated in each instance?

A. In the outset of these experiments the dilutions which were made ranged from .02 of a cc. to 1 cc. It was found 10675 upon making these tests, that the number of organisms which grew upon the culture medium when we employed Drigalski medium inhibited to such extent the water bacteria which were normally present in the water that by far the large majority of organisms which appeared upon the plate showed, so far as culture examinations were concerned, the typhoid character and this made it unnecessary to employ larger quantities of water because of the great preponderance of the typhoid organism, when cultures were made with large quantities of water.

Q. In making the final test as to whether the colonies fished were typhoid, did you subject them to the Widal test?

A. Yes sir.

Q. State whether or not in your opinion the water contained in these sacs represented the bacterial condition of the water in the Illinois River at Averyville, at the place where the sacs were submerged, during the whole time they were submerged, aside from the change brought about bcause of the additional numbers of typhoid bacilli?

A. The water which was used in the making of these experiments was taken from the river at approximately the point where the sacs were immersed. Inasmuch as the germ 10676 content of a flowing stream is subject to fluctuations, depending upon the amount of sediment and numerous other factors which modify the germ life found in a given body of water, the sample of water placed in the sac would not and could not under any condition, be exactly the same in germ content as was the case in the water flowing past these sacs for the period of time covered by the experiment.

Q. State, Professor, whether or not there was any substance of any kind found on the exterior of the sacs, while they were deposited in the water?

A. After the sacs had been left in the water for various periods of time, a reddish spot appeared upon the sacs. When first observed these were about the size of a pin head, and gradually increased in diameter until they reached a diameter of a half to three-fourths of a cc. These spots never became confluent, that is the surface of each sac never was completely covered with the same, and these spots increased in considerable number, but at no time did the aggregate growth of the fungus cause this spot to equal more than a small fraction of the entire periphery of the sac.

10677 Q. Did you examine this coating or covering of the sac, or these small red spots under the microscope?

A. These were examined and it was found that these were due to fungus which was capable of growing upon the exterior of the sac.

Q. Did not this growth in a measure cause the sac to become impervious?

A. No sir.

Q. To no extent whatever?

A. Not in any way did it produce an impervious condition in the sac.

Q. Did you use any other character of sac except the parchment sac?

A. No sac, no sir. The other series of experiments were made with agar blocks and not sacs.

Q. May not some typhoid fever bacilli, coming from human patients, be possessed of greater inherent vitality than the ones used in the series of experiments conducted by yourself, Professors Zeit and Jordan?

A. It is well recognized that cultures which have been grown upon artificial media gradually lose their virulence and also their power of retaining their vitality, and just in order to meet this objection for the purpose of this experiment freshly isolated cultures were taken from the bodies of three
10678 typhoid patients, one from blood, one from the urine and one from the feces, in order that the possible variations which might occur when such laboratory cultures were employed could be obviated.

Q. May not other cultures have been obtained from human feces, or of the urine which were possessed of greater inherent vitality than those used?

A. It is well recognized that there is a certain variation in the inherent vitality of pathogenic organisms, but it is my opinion that when three cases are taken freshly isolated from the human body, and when these cases are not in any way connected with each other, through the medium of the same outbreak and therefore presumably given as wide a range as would normally be found among typhoid bacilli coming from human sources, then it is quite improbable that typhoid organisms, as they normally occur in man, would ordinarily possess a degree of vitality which would much exceed those which are represented by the three cultures employed.

Q. Taking into consideration the care and precaution that was used by you in making the determinations contained in the tables which you read in advance, in your direct testimony, and assuming that typhoid fever dejecta is deposited into a running stream which flows for a period of nine days, at
10679 which point the inhabitants of a city receive their water
supply, and knowing that you had observed the presence of the typhoid bacilli during the series of examinations which you made in the water at that point—assuming the bacterial contents of that water to remain or be practically as contained in the sacs with which the observations were made, would you recommend that water as free from typhoid bacilli, and therefore suitable for domestic and drinking purposes?

A. Taking into consideration the fact that typhoid organisms deposited in running streams would not be subject, under natural conditions to such conditions as outlined in the foregoing question, for the reason that in such flow there are factors operative and always operative which are not assumed in the foregoing question, and which must be assumed if the conditions are made to refer to conditions that actually do obtain in a flowing stream, and taking into consideration all the knowledge which I possess from a bacteriological analysis of waters so exposed and the conditions which are referred to, it is my belief that waters discharged into a stream, the character of which corresponded to the conditions which are assumed in the question but which under such conditions are affected by
10680 these other factors which are always operative, it is my
opinion that typhoid organisms would not be found in such waters when a period of flow was of nine days duration.

Q. But, Professor, assuming aside from the natural conditions that the water remained in the river as it remained in the sacs for nine consecutive days, and in the ninth day you found typhoid bacilli present as shown in your observations, would you consider that water as being free from typhoid bacilli, at the end of the ninth day?

A. It would be impossible to base a recommendation of such a character unless all the facts which bear upon this question were taken into consideration, and if those facts were in accordance with the facts as represented in the experiment referred to in which analyses were made in large numbers and at daily intervals, and in which out of this series of analyses the typhoid organism was found abundantly the first day, the second day and the third day, but was not found at any subsequent date, although frequent daily examinations were made, except in one single solitary instance, on the ninth day, and was found in no instance thereafter, although examinations were continued for double this length of time, I should under these cir-
10681 cumstances consider that I was warranted in assuming that the typhoid organisms introduced in such water would have disappeared so completely that under no conditions would the water have been able to have produced disease if it had been consumed by human beings.

Q. And under the facts assumed, and at the end of the ninth day, and at the point, the end of the ninth day, you would recommend to the people that they could drink that water with impunity so far as the effect of the typhoid fever germs were concerned?

A. The recommendation as to whether a water supply is pure or suitable for domestic use presupposes conditions which are not assumed in the foregoing question and which must of necessity be taken into consideration before any such recommendation can be made, and a water supply which is known to contain typhoid bacilli must therefore be subjected to exceedingly stringent examination before one would be warranted in making any such recommendation as indicated in the question.

Q. Do you mean a stringent examination for the purpose of determining the presence or nonpresence of typhoid bacilli?

A. I do.

Q. Do you consider the observations and examinations
10682 which you made of the water contained in the sacs, as

shown in your tables, to be a stringent examination of that water, for the purpose of detecting the presence or non-presence of typhoid bacilli?

A. I consider that the examinations which were made of the analysis of this water were sufficiently stringent to have detected the presence of the typhoid bacilli if such had been present.

Q. Then under the conditions assumed in the preceding question that if water in a running stream ran nine days was, during the time in the same bacterial condition as the water contained in the sacs which were used in your experiments, and underwent the same bacterial changes, containing typhoid bacilli which also underwent the same changes, that water would be suitable for drinking purposes at the end of the ninth day and at the place reached at the end of the ninth day?

A. The conditions which were stated in the assumptions named in the question are so entirely foreign to what do exist when waters find their way in a flowing stream that a comparison which is made between the conditions of this experiment and the conditions which would occur when typhoid organisms
were deposited in a running stream for nine days flow,
10683 are such that I am unable to state exactly what would
occur under the conditions assumed, but when I take into consideration the fact that in a case of water containing approximately 5,400,000 typhoid bacteria in a given volume, that an exposure of that water under the conditions as described in the foregoing answers failed to reveal the presence of typhoid organisms in all but one case out of the entire number examined on the ninth day, so that the vitality of this enormous number of organisms had been entirely lost with the exception of the single germ referred to, except in the case of the first three days, when typhoid organisms were demonstrated, I should consider that a conclusion which is based upon the results which were obtained in the case of this single organism alone and not the whole of the results of the experiment are not proper as indicating what the condition of affairs would be which would occur in nature.

Q. Professor, only two examinations were made of all the samples in all the sacs by you on the ninth day. Is that true?

A. It is. Two samples of water removed from two different sacs and from those two sacs a number of separate and individual tests were made, and from these individual tests 18 suspected typhoid colonies were removed and examined.

10684 Q. On the ninth day no samples of water were taken from the sacs except sac number 13 and sac number 15, in which case only one sample of water was taken from each sac and analyzed?

A. The quantity of water that was removed in each instance was much larger than the quantity which is necessary for making a bacterial examination and from this large sample a number of separate and independent tests were made in each case.

Q. State whether or not the water taken from the sacs was diluted before analyzed?

A. I am unable to answer that question specifically, but it was our custom, owing to the relatively small number of water bacteria which appeared in the plates, to use the samples of water for inoculation purposes, directly into the media without dilution.

Q. Is it not a fact that of the water analyzed on the ninth day only 18 colonies were specifically examined?

A. It is a fact that of the water which was analyzed upon the ninth day a much larger number of colonies were examined than is shown in the existing table, but that the 18 colonies which appear in the existing table were colonies which in
10685 a majority of cases were regarded as presumptive typhoid colonies which were therefore selected for this purpose, but it should be kept in mind that these were selections made from a large number of colonies which appeared in the latter plates.

Q. The 18 colonies fished off, that represented the number of colonies that were subjected to the Widal test? Is that true?

A. The colonies of course which were represented upon the culture plates and not fished for further identification were not tested for Widal reaction, but in these cases all the tests were applied to the organism which was sufficient to identify them as typhoid or not.

Q. And on the tenth day 46 colonies were the only ones that were subjected to the Widal test?

A. The number of colonies fished as reported in the table were all of them subjected to the various tests employed to determine their typhoid nature.

Q. And that is true with reference to all the colonies or the various ones shown on the tables?

A. Yes sir.

10686 Q. Professor, what particular significance do you attach to the use of the agar blocks as distinguished from the Drigalski plates, in these experiments?

A. The experiment made with the agar blocks approached the problem from a materially different point of view and one which in my judgment would favor materially the retention of the vitality of the typhoid organism, but recognizing the importance in an experiment of this sort of attacking the problem in hand from as many different points of view as possible, it was deemed advisable to make simultaneous tests with this method of the agar block.

As outlined in the direct examination the typhoid bacteria in these blocks were prevented from coming in contact with the water bacteria by a screen of agar which was in all cases approximately 1-4 to 3-8 of an inch in thickness. This agar screen would permit of the passage of soluble substances, but not the organisms themselves, and so the conditions would in all probability be less prejudicial than was the case in the parchment sacs.

Q. These observations as shown on the table which you read in evidence in your direct testimony represent the only bacteriological analysis of the water in the Illinois River
10687 or the drainage canal that you have personally made or that has been made under your supervision?

A. These represent every independent analysis that was conducted on the water of the Illinois River at Averyville, and in this connection I wish to restate the fact that none of these determinations as to the complete identification of the typhoid organism could be made or was made until all of the samples of the sacs were removed from Peoria and the station at this city discontinued.

Q. Where was the plating done?

A. The plating was done in the bacteriological laboratory of the Bradley Polytechnic Institute at Peoria.

Q. This work was not done, as I understand you, personally by yourself, but by your assistant?

A. The work at the Peoria station was carried out under my direction, by my assistant, Mr. E. C. Hastings, who performed the routine work of packing and shipping the cultures to me at Madison for study and identification.

Professor, in your direct testimony you stated that you were familiar with the typhoid mortality of the various
10688 cities situated on the water sheds of the Missouri River above the city of St. Louis. In making that statement it is a fact is it not that you obtained your information from the certificates or copies of the certificates of the health officials of the various cities exhibited to you by counsel for the defendants, and you did not obtain your information upon a personal inspection of the records in the various offices in the various cities?

A. It was.

Q. You obtained no other information and included no other statistics or mortality records in your testimony than were presented to you by counsel for defendant?

A. The answers to the questions on these subjects assumed the statistics with reference to the typhoid statistics of these cities as previously presented in evidence by other persons.

Q. And those tables have already been introduced in evidence or as you understand it are to be?

A. They are.

Q. Your statement to the effect that you had examined the typhoid statistics of the city of St. Louis was based altogether upon what you obtained from the health reports of the
10689 Health Department of the city of St. Louis?

A. They were.

Q. The published report?

A. They were extracted from the published reports.

Re-Direct Examination
By Mr. Todd.

Q. What are the conditions not assumed in the hypothetical question of Mr. Jeffries to which you referred as existing in nature and not included in the question wherein he asked you if you would recommend water after the flow of nine days from the point of infection, infected and of the quality as contained in the sac used in the experiment?

A. The conditions as I comprehend them from the question asked imposed conditions which I do not think could possibly obtain in the waters of a running stream, inasmuch as the conditions of the experiment precluded the operation of factors which are known to exert a deleterious influence upon the vitality of the typhoid organism, and further that the conditions which do so obtain are conditions which would lessen this vitality in comparison with that which would be obtained in the experiment mentioned, and that the results of the experi- 10690 ment in which the bacteria of typhoid fever were entirely killed in a period of three days, with the exception of the single instance referred to, lead me to consider that no importance is to be attached to the presence of this single organism in determining whether the typhoid organism would be able to exist in flowing water after a period of flow measured for nine days.

Q. With these assumptions supplied as you have indicated, what recommendation would you make, for domestic and drinking purposes, under the conditions obtained in the hypothetical question as to the quality of water after running nine days from its source of infection, assuming that all other sources of infection were eliminated?

Mr. Jeffries: I object to the question for the reason that the witness himself has undertaken to put to himself other assumptions which were not embodied in my question asked in cross examination. I object to the question for the further reason that it is improper redirect examination and if counsel desired the witness questioned upon any such assumptions, it should have been asked in direct instead of redirect.

A. Assuming that all of the sources of infection are eliminated when water was exposed under natural conditions in a flowing stream, I should regard this period of flow as suf- 10691 ficient to result in the destruction of the typhoid organism, and would therefore regard such supply as not capable of producing typhoid disease.

MR. JEFFRIES: I move to strike out the two questions asked in re-direct examination and the answers given thereto for the reason that there is nothing in the assumptions in the questions or in the answers that would preclude the witness from answering the question upon which the first question of this redirect examination is based.

H. L. RUSSELL.

ADJOURNED until 10:00 A. M., Monday, February 22,

10:00 A. M., Monday, February 22, 1904.

10692 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing respective parties. Also Hon. John G. Drennan, representing the Sanitary District of Chicago.

ISHAM RANDOLPH

a witness called on behalf of defendants, after being duly sworn by the commissioner, testified as follows:

Direct Examination

By Mr. Todd:

Q. What is your name?

A. Isham Randolph.

Q. What is your business?

A. Civil Engineer.

Q. How long have you been a civil engineer, Mr. Randolph?

A. I began that line of work in 1868.

Q. Are you a graduate of any technical institution of engineering?

A. I am not?

Q. From what source did you gather your engineering knowledge?

10693 A. From practice, observation and study.

Q. Will you give your engineering experience, commencing with 1868?

A. In 1868 I entered the service of the B. & O. Railroad Company as an ax man, on the Winchester & Strausburg Extension of that line. I remained with that road in the capacity of ax man and later as rodman until its completion in 1870. In 1870 I went to the Washington & Ohio Road as leveller and surveyed from Round Hill in Lowden County through the mountains to Winchester, Virginia. After the surveys and estimates were completed I went into the service of the Lehigh Valley Railroad. My recollection is that that was the fall of 1870, locating the extension of that line from Jugtown Mountain to Perth Amboy, New Jersey. My next engagement was with the B. & O. Railroad. I entered their service in March, 1872, as transit man, on the survey from Syracuse, Indiana, to Chicago. I had charge of the locating party on that line, locating 110 miles of the road; later building 27 miles of it, and building the round house and shops for that company at South Chicago.

After the completion of that work engineering was pretty
10694 dull and the best thing I could get was book keeping and
draughtsman in a plumbing shop in Richmond, Virginia, and I staid there until the first of January, 1876, when I was invited to a position as assistant engineer on the Scioto Valley Railway in Ohio. After the completion of that road I was its roadmaster. In 1880 I was offered the position of Chief Engineer of the Chicago & Western Indiana Railroad and the Belt Railway of Chicago. I took charge of that work on the 1st day of May, 1880, and remained with that company for four years. I then opened an office for general engineering work in Chicago and in 1886 I went into the service of the Illinois Central Railroad to locate and build the Chicago, Madison & Northern Railroad, and the Freeport and Dodgeville Railroad.

After that work I opened an office in Chicago, in 1888, and did general railroad and municipal work. I was consulting engineer for the B. & O., for the Union Stock Yards & Transit Company, the Chicago & Calumet Terminal R. R. Company, and for the Stickney project, the Transfer Yards.

In 1893 I was tendered the position of Chief Engineer of the Sanitary District of Chicago, was elected to that office on the
7th day of June of that year, and have continued as such
10695 Chief Engineer ever since.

In 1893-4 I was the President of the Western Society of Engineers.

Q. What were and are your duties as chief engineer of the Sanitary District of Chicago?

A. As Chief Engineer I am responsible for all the work coming under the general term of engineering, the preparation of plans, the preparation of forms of contract, the supervision of the work of construction and the enforcement of all contracts for engineering work.

Q. Describe the conditions of the Chicago River as they were in 1880 and as they continued to be until 1900?

A. My first familiarity with the Chicago River grew out of the fact that the Western Indiana Railroad Company purchased a considerable length of river front, extending from Stewart Avenue up to Sixteenth Street. This river front I had to re-dock and fill in slips and make available for elevator and railroad yards. This brought me in constant visual contact with the Chicago River. It was at that time and remained for many years thereafter a very foul stream, the water black and ill smelling and often covered with a slime, a black slime, 10696 and in the summer seasons there was a great deal of agitation of the waters due to gases arising from the putrescent matter in the water.

Q. Give the effect upon the Chicago water supply resulting from the pollution of the Chicago River?

Mr. Jeffries: I object to the question because the witness is not a sanitarian and has not qualified as such.

A. The Chicago River at that time was a body of water which sometimes flowed up stream and sometimes down stream. Under ordinary lake conditions there was a very, very slight current to the westward, due to the pumping works at Bridgeport.

When the lake was rising the water came in the river quite rapidly. When the lake was falling the flow was in the opposite direction, towards the lake, and in times of freshet there was a strong flow towards the lake. In times of freshet the Bridgeport pumps had to be suspended, and whenever the flow was towards the lake the foul waters of the river passed out into the waters of Lake Michigan, and when there was a freshet, accumulated filth of the river was swept out into the lake and went out for long distances, and the consequent effect of 10697 putting foul water into pure water was to diminish the purity of the water into which it was put.

Q. Did this condition of the Chicago River, which you have just described, obtain up to 1900?

A. It did.

Q. Will you describe the sewage system of the city of Chicago, the levels of the sewers, the outfalls of the sewers, and at what points these sewers emptied either in the Chicago River or Lake Michigan, up to 1900 and prior thereto?

A. The territory north of Twelfth Street, the business part of the city, all drained by sewers leading directly into the Chicago river. Those sewers did not drain towards the lake. Some of them entered the main river and others the south branch of the Chicago River. As I remember it at that time there was a sewer on Twelfth Street which discharged directly into the lake; the Twenty-second Street sewer discharged directly into the lake. Each one of those had a large contributary population. The West Side sewers also discharged directly into the river, either into the North Branch or into the South Branch. Those that I recall now—I have not a very clear mental photograph of the conditions on the north branch for I never examined any of the sewers entering the north branch. I simply knew in a general way where they came in.

10698 On the south branch there were sewers entering at Randolph Street, at Washington Street, at Madison Street, at Harrison Street, at Polk Street, at Taylor Street, at Sixteenth Street, at Eighteenth Street and Twenty-second Street, and Main or Troupe Street, at Loomis Street, at Ashland Avenue and at Western Avenue.

On the south branch—or rather the south fork of the south branch received all the sewage from the stockyards district and the discharge from two trunk sewers coming in from the south, taking the sewage from the large population on the south of Thirty-ninth Street.

The conditions in the south fork of the south branch were more distressing and more disgusting than any other part of the river. There was more organic matter coming in there from the stock yards than any other branch of the Chicago River.

With regard to Twelfth Street I have no personal recollection of seeing the outlet to that sewer in the lake. I always understood it went into the lake. It is now reversed and flows in the opposite direction, but at Twenty-second Street there is a large sewage entering the lake at that point, and I do not recall the street numbers at which other sewers empty, although

10699 I have seen them, but from Twenty-second Street all the way down to South Chicago there were sewers entering the lake at various points. A part of that territory was so flat that the only way a discharge in the lake could be secured was by putting in sewers which were drained to a central well, where pumping works were established and the sewage pumped from these wells into sewers which were discharged into the lake.

Q. Have you a map in your office showing the location of all sewers in the city of Chicago emptying into Lake Michigan, and those emptying into the Chicago River and its various branches?

A. Yes sir, I have.

Q. Will you describe the map to which you refer?

A. The map to which I refer is published in one of the reports of the Commissioner of Public works of the city of Chicago. It is an uncolored map. It is in black and white and the sewers shown by black lines and with the sizes of the sewers given in figures.

Q. Will you produce the map to which you refer and make it a part of the record?

A. The witness produced the map which is as follows:

FOLD-OUT IS TOO LARGE TO BE FILMED

Q. The map that you have introduced is a correct representation of the sewage system of Chicago is it not? 10701

A. I believe it so to be. When Chicago was a young city the surface was so slightly above the level of the lake, it was impossible to put in sewers, the drainage was all in open ditches, and during Mr. Chesborough's administration of the Engineering Department of the city, he planned a sewage system which required the elevation of the grades of the streets. This street level admitted the putting in of sewers which would have fall enough to produce a flow towards the outlet. That slope is very slight, indeed; in many instances it is as small as half an inch to 100 feet, and I think I recall instances where it is even less than that. The result of this is that there is often an accumulation of organic matter in the sewers which is flushed out in times of heavy rainfall or melting snows.

At one time it was the habit in the city to flush them mechanically. They had very large square tanks, mounted on trucks, that took from four to six horses to haul them around, and they would stop this tank over a manhole and let down a spout in the man hole, open the valve and empty the water from the tank into the sewer and flush it in that way. They were kept flushed for many years in that way. 10702

Q. Are you acquainted with the Illinois and Michigan Canal?

A. I am.

Q. Will you describe the Illinois and Michigan Canal and its source of water supply?

A. The Illinois and Michigan Canal was commenced about the year 1836 and completed in 1848. It extends from a junction of the south fork of the south branch of the Chicago River in the city of Chicago and in a southwesterly direction across the divide between the Lake Michigan watershed and the Illinois Valley watershed, through to Peru Illinois, a distance of about, as I remember it, ninety-six (96) miles. This canal had a navigable depth of about 5 feet and a navigable width of about 60 feet. Its locks were 110 feet long and 18 feet wide. What is known as the summit level extends from the south fork of the south branch of the Chicago River, through to Lockport, a distance of about 29 miles. The summit level since 1884,

I think it was, has been supplied by pumping works
10703 located at Bridgeport in the city of Chicago. The
pumps were under a gauranteed capacity of 60,000 cubic feet per minute. Prior to the erection of the pumps of which I have just spoken the summit level was supplied by water coming in through what is known as the Sag Valley. There was a dam at Blue Island, draining off the Calumet River and dividing its flow, a portion of it through a shallow channel, dug for the purpose, and conveying it into the Illinois and Lake Michigan Canal at Sag Bridge. At a period prior to 1870, the date I do not recall, this supply became inadequate and pumps constructed on the principal of the stern wheel to a stern wheel steam boat were put in at Bridgeport, for the purpose of supplying water for this summit level. At some time prior to 1870 the city of Chicago undertook to deepen the summit level and get a gravity flow from the lake through the canal. This work was in progress at the time of the Chicago fire, and a very large sum of money had been expended by the city, something approximating $1,000,000.00, or a little more, I think, and after the Chicago fire the State of Illinois refunded this expenditure to
the city. This gravity flow proved inadequate because
10704 the channel had not been made deep enough and pumping works were again established at Bridgeport and the pumps that were put in had a guaranteed capacity of 60,000 cubic feet per minute and lift between 4 and 5 feet. As a matter of fact those pumps did not in practice accomplish what they were claimed to do, and the flow fell to in the neighborhood of 50,000 cubic feet. It ranged between 45,000 and 50,000 cubic feet a minute. This supplied the summit level from Bridgeport to Lockport and the intermediate level between Lockport and the upper pool at Joliet. At Joliet the canal and the Desplaines River flowed together through the upper pool as far as dam number 1. At dam number 1 there was a lock called lock number 5, which passed the flow from the upper pool to the middle pool. The middle pool was created by the building of dam number 2 at Jefferson Street in the city of Joliet. At dam number 2 the river and the canal again separated and the canal had an independent course from that point through to LaSalle, where it emptied into the Illinois River. The supply of what

is known as the Chanahan or twelve mile level extending from Joliet to Chanahan was taken from the Desplains River at its junction with the waters coming through the canal from the Bridgeport pumping works. At some seasons of the year the supply of water from the Desplaines was very small indeed, and the canal was almost wholly dependent for its avail-
10705 ability as a navigable stream upon the waters pumped from Bridgeport.

Q. When were these pumps placed at Bridgeport?

A. They were completed in 1884.

Q. By whom were those pumps constructed?

A. You mean what machine company?

Q. Yes sir?

A. They were constructed under a contract with the city of Chicago, and paid for by the city of Chicago.

Q. From what source was the water pumped into the Illinois and Michigan canal by the Bridgeport pumping works?

A. The forebay from which this water was pumped connected directly with the south fork of the south branch or what was known as the Stockyards branch. The water entering the pumps came partly from the stockyards branch and partly through the south branch of the Chicago River from Lake Michigan. There was a certain small flow of water due to sewage discharged into the stock yards branch which met the flow from the lake, and the two mingled and were drawn into the pumps.

Q. Have you a table showing the amount of water pumped from the Chicago River by these pumps at Bridgeport?

10706 A. Our own tables give that pumpage since 1900. Reports of the commissioner of Public Works gave it for previous years.

Q. Are those reports published?

A. Yes sir.

Q. Will you tell of the conditions in the summit level of the pools in Joliet?

A. The water flowing through the summit levels at a very slow velocity, probably a mile an hour, was a black liquid, with a very foul odor, and would leave a greasy black stain on anything that was put into it. The water in the two pools at Joliet was at some seasons of the year as bad as that in the canal proper, because there was so little dilution coming in from the Desplaines River, and it was only bettered by what water came in from the Desplaines river. At some seasons of the year that flow was large, and the conditions were very much improved, but in the dry seasons they were foul, horrible pools.

Q. Were you acquainted with the condition of the water in the Illinois and Michigan canal from Chicago to LaSalle? And if so state how the conditions of the water in the Illinois and Michigan canal at Ottawa and points below compared
10707 with conditions that obtained in the upper stretches of the Illinois and Michigan Canal?

A. I have never traversed that stretch of the Illinois and Michigan canal from Joliet to Ottawa by boat. The stretch from Ottawa south I have traversed by boat. At Ottawa I made a careful investigation with the eye and the nose only of conditions, and at that point I could not detect anything whatever by the eye or the nose, which indicated that the water contained sewage. From there on down the conditions were as good as they were at Ottawa and probably improved continually as we went down.

Q. Will you give the history of the Sanitary and Ship canal?

A. The sanitary and ship canal has been the outcome of Chicago's necessities. The conditions affecting Chicago's drinking water had gotten steadily worse from the days when it begun to be a city. The conditions were such that the public generally was excited and the public men of the city determined to see what could be done to relieve the city.

It reached a period in 1886 that the city council authorized the mayor, the elder Carter H. Harrison, to appoint an expert commission to decide what should be done for the city.
10708 That commission was appointed, I think in January, 1886, and Rudolph Hering, then of Philadelphia, was made the engineer in charge. His associates were Benizette Williams and Samuel J. Artingstall. These gentlemen were authorized to employ expert help, to make surveys and investigations and to prepare a report accompanied by their recommendations. The final report of this commission was never made. The preliminary report I have seen, and in fact there is a copy

of it in the report of Major W. L. Marshall, accompanying his report to the Governor, I think for the year 1889. In 1889 the Sanitary District law was passed, authorizing the formation of drainage districts in the State of Illinois.

Under that law a board of trustees was elected, consisting of nine members, with power to organize, decide upon plans, levy taxes, enter into contracts and prosecute the work as to them seemed best. This board adopted the project for a water way from Chicago to Lockport, this water way to cause a flow of the waters of Lake Michigan through the Chicago River and through the channel which they constructed artificially and discharged in the Desplaines River at or near Lockport, Will county, Illinois.

10709 Q. Will you describe the general outlines of the sanitary and ship canal?

A. The sanitary and ship canal follows the general location of the old Illinois and Michigan canal from Chicago to Lockport. It traverses the territory which is partly tributary to Lake Michigan and partly to the Illinois water shed. It connects with the west fork of the south branch of the Chicago River at Robey Street in the city of Chicago; runs in a southwesterly direction through a clay formation and crosses the divide near the "Summitt Range line." The lowest point in the divide between the water shed of the Illinois, the Desplaines valley and that of Lake Michigan is almost on this summit range line.

Before the building of the "Ogden ditch" the natural surface at its lowest point was 11.72 feet above Chicago datum. Chicago datum is a plane of reference adopted for horizontal elevations by the engineers of the Illinois and Michigan canal when its construction was entered upon. It so happened that this elevation corresponded with the low water of 1847 and hence Chicago's datum is always spoken of as the low water of 1847.

Q. Low water in Lake Michigan?

A. Yes sir. The first seven or eight miles of this chan-
10710 nel is through a clay formation a formation which can
be readily dredged, and the cross-section of this stretch of the channel is now less than what it is to be ultimately. It

is only 110 feet wide on the bottom; the side slopes being 1 foot vertical to 2 feet horizontal, giving a surface width with a minimum depth of water 22 feet, of 198 feet. At the end of this stretch of channel material was encountered which could not be readily dredged. It is described in our specifications as glacial drift. There the full size channel was entered upon. This full size channel is 202 feet wide on the bottom with side slopes as before of 2 feet horizontal to 1 vertical, and the resulting width at the water line is 290 feet with a minimum depth of water 22 feet.

This cross-section of the channel is held for 5.3 miles until Willow Springs is reached; there the rock was encountered. The territory from there on to Lockport is either wholly rock or is underlaid by rock.

The channel contracts at this point to 160 feet in width. The grade is increased from 1 foot in 40,000 feet, which 10711 is equivalent to an inch and 5/8 to the mile, to 1 in 20,000 feet.

The length of this cross-section is 14.95 miles. Seven miles of this distance is through cut in rock, the sides are cut practically vertical with two offsets of six inches each on each side, so that the surface width is 162 feet. Wherever the rock did not come to the surface, walls were built from the rock at the elevation found to a height of five feet above Chicago datum.

It was necessary that perfect control of the flow through this channel should be maintained and to accomplish this, controlling works were erected at Lockport. These works consisted of seven lifting gates of the Stoney type, and one bear trap dam. The gates have an opening of 32 feet each. They are counterbalanced and operated by winches, so constructed that two men can raise or lower the gates under pressure, although each gate weighs 62,000 pounds.

The Bear Trap dam was adopted because it was desirable to have a movable dam which could be raised or lowered to admit of the passage of ice or drift from the channel. The original bear trap dam dates back to 1836 and was invented 10712 by Hazard and White. The one which we are now discussing is the largest ever attempted. It has 160 feet clear water way with possible oscillation of 17 feet. The dam itself is essentially two immense leaves of steel. The down stream leaf hinged at its lower side to massive masonry, the up stream leaf hinged to the down stream leaf like the backs to a book. The up stream leaf plays free upon a masonry barrier or a dam, and is supported at intervals of 2 feet upon wheels which travel on tracks bedded in this masonry dam. The dams fit in between the masonry bulk heads with only sufficient play between them to keep from binding. The space beneath the dams forms a water chamber which is supplied by a tunnel running the full length of the dam. Water is admitted to this channel through valves operated by hand power. There is a discharge conduit beneath the dam to operate the dam. The process is as follows: If it is to be raised the valve controlling the discharge of water from beneath the dam is closed and the intake valve is opened. The water rushes into the chamber below the leaves and forces the leaves up. This is done until the proper height is reached when the discharge valve is opened and the intake valve adjusted so that there should be a steady flow through the tube. The volume of water is kept constant 10713 under the dam. To lower the dam the intake valve is closed and the outlet valve is opened. The water flows out of this chamber beneath the dam and it settles down. The whole mechanism can be operated by one man. It operates so perfectly that the Stoney gates are rarely used. The entire flow can be shut off in five minutes time and in as many more minutes a flow of 400,000 cubic feet per minute can be discharged over the dam.

Q. Will you describe the bridges that have been constructed across the drainage canal and why these bridges were constructed?

A. There are thirteen bridges across the drainage canal, 7 of these are highway bridges and six are railroad bridges. They are all of a movable type. The sanitary law compels this style of construction as it is to be a navigable channel.

The first of these bridges is a double roadway bridge at Western Avenue; one roadway being devoted to the avenue, to commercial traffic and the other to Marshall Boulevard traffic. 600 feet away is an eight track bridge. This bridge is essentially four double track bridges side by side of the Bascule type.

10714 Two tracks crossing this bridge belong to the Chicago Terminal Transfer Railway, two to the Union Stockyards & Transit Company and 4 to the Pittsburg, Cincinnati, Chicago & St. Louis Railway.

The next bridge encountered is the bridge of the Chicago, Madison & Northern or Illinois Central Railroad, a double track railway bridge.

The next is a bridge on Kedzie Avenue and following this is a double track railroad bridge of the 26th Street line of the Santa Fe Railway.

The next bridge is at the city limits, a four track railroad bridge built for the Chicago & Western Indiana Belt Railroad. There are three other double track railroad bridges and six highway bridges.

With the exception of the eight track bridge, all of these crossing the earth channel are center pier structures. The bridges crossing the rock channel are what is known as bob-tail or counter balance drawers. The pivot pier is located on the right bank of the canal and there is no obstruction in the channel.

Q. When was the work first begun on the sanitary and ship canal and when was it completed?

10715 A. Work was begun on the 3rd of September, 1892. The water was let into the channel on the 2nd day of January, 1900.

Q. After the water was let in what was done before the water was turned over the Bear Trap dam?

A. The inspection of the State Commission had extended over nine months prior to this date, and on the 16th day of January, we got the commission together to ask them to recommend to the Governor that we be permitted to open. In fact we did not get them together until the morning of the 17th. We started out after them on the 16th and got them all corralled by the morning of the 17th. The Governor was gotten by telephone, from Joliet, and after considerable parley he authorized the turning on of the water and wired his consent. We then proceeded to Lockport and the president of the commission in the name of the State of Illinois authorized the Board of Trustees of the Sanitary District to lower the Bear Trap dam and caused the waters to flow to the westward.

Q. How long did it take for the water of Lake Michigan to fill the channel?

A. The water was turned in on the morning of the second and it was filled to the level of Lake Michigan by the morning of the 14th.

10716 Q. What was the date that the water flowed over the Bear Trap dam or the time that the dam was lowered for the water of Lake Michigan to flow over the dam?

A. 11:05 a. m., January 17, 1900.

Q. What work has been prosecuted on the Chicago River since the opening of the drainage canal by the sanitary district of Chicago?

A. The work of executing the plans of the district had gone steadily on. The Chicago River as it was in 1898 did not afford an adequate channel to supply the water which the Sanitary District law required us to flow through our channel. Prior to the beginning of work by the Sanitary District the flow through the Chicago River would have been limited to 150,000 cubic feet and the plans of the sanitary district provided for widening the Chicago River uniformly for 200 feet, deepening it for the central 100 feet to 26 feet below the water surface, making the depth at the dock lines 16 feet. This would give the river a capacity of 480,000 cubic feet per minute, and a velocity not exceeding a mile and a quarter per hour.

10717 The district is also engaged in removing center pier bridges from the river and substituting therefor Bascule bridges. We have completed seven Bascule bridges. We have two now under contract. We have the plans under way for four additional bridges, in fact that are partially completed, and we propose to do away with the center pier bridges in the Chicago River.

Q. How many bridges do the plans adopted for the improvement of the Chicago River contemplate?

A. Twenty-two bridges.

Q. In addition to the main drainage and ship canal and improvements of the Chicago River what other work in connection with that improvement has been prosecuted by the sanitary district?

A. The channel of the Desplaines River south of Lockport was entirely inadequate to the demands which would be made upon it by the combined flow of the flood waters of the Desplaines and the discharge from the sanitary and ship canal. It was therefore necessary that the district should deepen and enlarge this channel which it has done to an extent which enables us to carry these combined waters safely through the city of Joliet.

10718 We have made a provision for a flow of 1,500,000 cubic feet of water per minute. For one mile south of the controlling works an entirely new channel was made for the Desplaines River; that brought us to the precipitate slope of the valley. There instead of making a new channel we bought the lands on each side which would be submerged. This method of caring for the water was adopted as far as the E. J. & E. bridge just north of Joliet. From that point into the upper basin we made an entirely new channel for the Desplaines. In the upper basin the width of which was 300 feet we deepened the basin to give a sufficient cross-section to carry the water which I have mentioned as 1,500,000 cubic feet per minute. We were compelled by the Illinois & Michigan Canal Commissioners to rebuild dam number 1 which we did. The middle basin we destroyed, tearing out dam number 2 and maintaining navigation in the Illinois & Michigan canal by building a channel for said canal from dam number 1 to the guard lock located at Jefferson Street. After tearing out dam number 2, which made the second pool, we widened and deepened the river between Jackson Street and Jefferson Street. We continued this
10719 widening and deepening from Jefferson Street through to a point about 800 feet south of the Rock Island bridge. From that point to the mouth of Hickory Creek, we built a massive embankment to prevent the over flow of the adjacent territory by the flood waters. We were compelled by the city of Joliet to build new bridges at Cass Street and at Jefferson Street.

Q. What is the grade from Robey Street to Lockport, through the canal?

A. The grade in the channel falls 5.62 feet, and with the minimum depth, the water surface is supposed to be parallel to that grade so that when there is only 22 feet of water in the nel which may happen sometimes, the fall of the water ce should correspond with the water in the channel, 5.62

Q. How long is the drainage canal from Robey Street to port?

A. 28.05 miles.

Q. How far is it from Robey Street to the mouth of the ago River?

A. Six miles.

0 Q. What is the grade from Robey Street to the Lake?

A. The theory upon which we based our work was that e would be a fall of 2½ feet. That has not been sustained. fall is about 2 feet now and that is being diminished as we ease the Cross-section of the river.

Q. Is the level of Lake Michigan variable?

A. Yes sir.

Q. To what do you attribute this variableness?

A. The widest fluctuations are caused by wind effects. fluctuations have amounted to something over four feet, rly five feet in fact.

Q. How is it that the wind creates this condition?

A. When the wind is from the southwest it drives the er off shore and piles it up on the Michigan side of the lake. en the wind is reversed the conditions are reversed and it s up on this shore of the lake.

Q. What has been the cost to the sanitary district of the itary and ship canal which it has constructed?

Mr. Jeffries: I object to the question as immaterial.

Mr. Todd: Answer the question.

21 A. The construction cost, up to the first of January, 1904, has been.............	$27,179,781.45
e completion account and the maintenance account	548,988.94
ministration account, in all its departments, engineering, clerical, law, treasury, police, and general account....................	3,828,615.45
ght of way, this covers also the buildings which had to be destroyed, etc................	4,808,338.17
terest on bonds	5,395,033.70

Interest on tax warrants	468,453.69
Taxes	24,062.45
Sundry accounts	249,894.95
Making a total of:	$42,503,168.80

ADJOURNED until 2:00 p. m., February 22, 1904.

10722 2:00 p. m., Monday, February 22, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. What were the boundaries of the Sanitary District as first laid out?

A. The original sanitary district took in all of the city of Chicago north of 87th Street, except a part of Roger's Park and Norwood Park, and 42 square miles of the country lying directly west of that portion of the city.

Q. Embracing in all how many square miles?

A. The original was 185 square miles.

Q. By what authority was this sanitary district laid out?

A. Under the general law of 1889.

Q. In the work done by the sanitary district of Chicago 10723 was all the work up to last July done under the law passed in 1889 and the amendments passed by the legislature prior to July last?

A. Yes sir, that is true.

Q. Do you know whether the last legislature of the state of Illinois passed any acts in connection with the sanitary district of Chicago?

A. Yes sir, it passed an act providing for the annexation of territory and for the building of water power by the sanitary district.

Mr. Todd: I offer in evidence a copy of an act to create sanitary districts and to remove obstructions in the Desplaines and Illinois River, approved May 29, 1889, in force July 1, 1889, and all amendatory and subsequent acts passed by the legislature of the State of Illinois since that time relative to the sanitary district of Chicago, and ask that the same be marked Randolph's Exhibit A.

Mr. Jeffries: It is conceded by the complainant that the exhibit is a true copy of all acts of the legislature of the State of Illinois as expressed in the offer of counsel in introducing the bills in evidence.

Which said document is marked by the Commissioner, "Defendant's exhibit, Randolph's exhibit A" so as to identify it as one of the defendant's exhibits.

10724 Q. Under the acts of the Legislature extending the boundary of the Sanitary District, passed at the last Session of the Legislature, what are the boundaries of the Sanitary district as they exist today?

A. Under this bill 78.6 square miles of territory was annexed on the north side, known as the North Shore District, and on the south side 94.48 square miles was annexed, known as the Calumet District. That completes the taking into the sanitary district of all the city of Chicago. The whole city is now in the sanitary district.

Q. Have you a map showing the territory of the sanitary district as it was first laid out and the present territory embraced in the sanitary district?

A. I have.

Q. Will you produce the map in evidence?

A. The map is as follows:

Q. Will you explain the map presented?

10726 A. The map shows the original sanitary district tinted in yellow. The annexed territory is tinted in pink and heavy black lines follow the outlines of the distirct. The original district is bounded by a heavy black line.

Q. What plans have been adopted for caring for the annexed district?

A. Well, I am not prepared to say that the plan has been adopted. I have been istructed to make surveys and prepare plans, which I have done. These have not been adopted by the Board up to the present time, but they seem to be the only things which are feasible to be done, and it is only a question of a short time before their adoption.

It is proposed to reverse the flow of the Calumet River by constructing a channel from a connection with the Calumet River near Blue Island. This channel extends southwesterly, through what is known as Sag Valley to a junction with the sanitary and ship canal at or near Sag Station on the Alton Railroad. This channel will reverse the flow of the Calumet River and prevent the discharge of its waters into Lake Michigan at all times 10727 except in excessive floods. Provision can not be made for taking the entire flood waters of the Calumet region through our channel. On the north it is proposed to extend the north branch of the Chicago River northward as far as Evanston and make a connection with Lake Michigan at that point, at a point almost on the boundary line between Evanston and Winnetka. The lake level being the same at this point of junction as it is at the mouth of the Chicago River, it will be impossible to get a gravity flow through this channel and therefore pumping works will be erected at the north end, designed to pump 60,000 cubic feet of water per minute into this new channel. Into this channel all the sewage arising along the north shore is to be delivered by sewers constructed for that purpose.

Q. The sanitary district as it is at present constructed has a population of how many, Mr. Randolph?

A. The population of the city of Chicago by the census of 1900 was 1,698,575. Making up the population curve, based upon past experiences and future probability, we bring that population down to 1903, as 1,878,000 at the end of the year.

Q. What is the total population of the sanitary district?

A. It is 1,942,000.

10728 Q. Where are the intakes for the water supply of the city of Chicago located and state how many there are?

A. Starting from the south the first intake is located about opposite 61st Street, and is about two miles from shore. The next one is very nearly opposite Taylor Street and four miles out in the lake. The next one is opposite Chicago Avenue—there are two there, one 2 miles out and the other 4 miles out. Then we come up to Lakeview and the intake is about 2 miles out in the lake and about opposite Mount Rose Street. Those are the sources of supply from the lake, and out at Washington Heights there are deep wells from which the water is pumped to supply that village and Morgan Park.

Q. What are the plans established by the Sanitary District for diverting the sewage of Chicago from Lake Michigan?

A. The general plan of the district for providing a means of carrying off the sewage has been described. The city in conjunction with the sanitary district is at work with a system of intercepting sewers both from the north and the south side. The city has built a conduit in 39th street, 20 feet in diameter, and having a capacity of 120,000 cubic feet of water per minute. At the lake end of this conduit a pumping station has been 10729 established in which there are to be six pumps. Four of these are put in by the city for pumping sewage from the intercepting sewers, sewage mingled with lake water. The combined capacity of the four pumps is 40,000 cubic feet a minute. The sanitary district puts in two pumps which take their supply direct from the lake without sewage pollution and each of those pumps has a capacity of 40,000 cubic feet per minute. They are the largest pumps ever attempted in the world. On the north side of the city on Lawrence Avenue, the city is building a conduit to receive the intercepting sewers. That extends from the lake across to the north branch of the Chicago River. The intercepting sewers bring in the sewage from the north and south into these conduits. The pumping station is to be erected at the cost of the city and to be operated by the sanitary district. This pumping station will have a capacity of 35,000 cubic feet of water per minute, with arrangements made for doubling that volume if it is found necessary, but the pumps will only be put in at present for 35,000 cubic feet per minute.

Q. Mr. Randolph, when the improvements contemplated by the sanitary district for the territory on the north and the Calmut on the south, as well as the system of intercepting sewers, and the canal itself in the earth section, and the Chicago River are completed, what will be the maximum capacity of the drainage canal, in cubic feet per minute?

10730 A. About 825,000 cubic feet per minute.

Q. Have you a table showing the flow of the canal as measured at the Bear Trap Dam, since its opening up to the present?

A. I have those tables compiled up to the middle of 1903. The compilation is not complete to date. These compilations come down to the end of June, 1903, from the date of the opening.

Q. Can you give the average flow per week for the year 1900, approximately, over the bear trap dam, through the drainage canal at Lockport?

A. For 49 weeks in 1900 the average was 188,136 cubic feet per minute. The smallest flow was on the 17th of September, 1900, 1863 cubic feet per minute, and the largest was on the 26th day of the same month, 326,791.

Q. During the period of 1900 were the dams at Lockport, entirely closed at any time?

A. My recollection is that they were for a few hours. I think it was on two or three occasions when vessels got stuck here in the channel, and it was shut off long enough to relieve them.

10731 Q. Were they closed for a sufficient length of time to reverse the flow of the current in the Chicago River so that it emptied into Lake Michigan?

A. I have no knowledge of the water ever flowing through to the lake but once since the channel was opened. Once there was a freshet in the north branch—it was a general freshet and it was not watched close enough to take care of it, and that flow began to go towards the lake, and as soon as that was noticed we checked it in a very short time.

Q. How long did that flow towards the lake last?

A. I can not answer that question but it was a very short time, probably two or three hours.

Q. With the exception of shutting down the flow for the purpose of getting off boats that were stuck on the tunnels in the Chicago River has the flow in the drainage canal been shut off for a period equal to a day?

A. No sir.

Q. What was the maximum, mean and average flow through the drainage canal in 1901, 1902 and 1903?

A. On March 16th was the largest flow of the year 1901,
406,227 cubic feet per minute. On October 3rd was the
10732 lowest, 139,427 cubic feet. The average for the year was
242,323.

Now, we will take 1902. For 1902 I find that the lowest flow was on June 3rd when the works were shut down for fourteen hours on account of the flood in Joliet, the Hickory Creek disaster, 107,231 cubic feet was the lowest. There was some water running all the time but not enough to interfere with the flood below. The largest flow was on December 26th, 339,610 cubic feet. The average for the year was 257,006 cubic feet.

For the first six months of 1903 it shows the greatest flow to have been on June 5th, 401,425 cubic feet per minute, the lowest May 30th 248,063 cubic feet, the average 312,692 cubic feet.

Q. Will you give the maximum, mean and average flow through the Illinois and Michigan Canal for the years 1900, 1901, 1902 and 1903.

Mr. Jeffries: Objected to as immaterial.

A. The highest record of the Illinois and Michigan canal was on February 8th, 57,677 cubic feet per minute. The lowest
when there was anything doing at all—there were a few
10733 days when there was nothing doing—was 14,800 cubic
feet. The average was 26,768 cubic feet per minute. That
is for 1900.

The canal appears to have been shut down entirely from the first of January, 1901, to the 24th of April, 1901. The minimum was on April 24th, 3,840 cubic feet: on July 3rd, the maximum was 29,206, and the average for the 26 weeks was 20,073.

In 1902 the pumps were started May 1st. The minimum was 9,200 cubic feet per minute, the maximum 25,080. The pumps were only run for 27 weeks, and the average 22,488.

The first six months of 1903, on January 13th, was the minimum, 1,913. On June 5th was the maximum, 28,114, the average for the 26 weeks 21,996.

Q. What is the per capita consumption of water in the city of Chicago?

A. It is varied, in different years. I have taken the tabulations for 1900, 1901 and 1902. The average per capita for 1900 was 190 gallons. For 1901 it was 195 gallons and for 1902 it was 197 gallons.

10734 Q. Will you state the maximum, minimum and average flow of the Desplaines River for 1900, 1901, 1902 and 1903?

Mr. Jeffries: Objected to as immaterial.

A. There were two periods during 1900 when there was no water flowing past Riverside at all. It was simply a pool, from May 31st to June 5th, and from June 26th to July 7th. The largest volume of water passing was on March 19th, 290,350 cubic feet per minute.

For 1901 there was a period from February 11th to March 2nd when there was only 2,400 cubic feet of water flowing per minute. About March 30th there was 331,680 flowing, and the average for the year was 20,974.

In 1902 there were several periods in the year when there was nothing flowing at all past Riverside and the maximum on May 26th was 37,740 cubic feet. The average was 30,235.

The first six months of 1903, the smallest flow was June 19th and 20th, 1,200 cubic feet per minute. The largest was March 21st, 437,520 cubic feet per minute, and the average was 1,307.

Q. Will you give the mean average flow of the Desplaines,
the Chicago Drainage Canal, the Illinois and Michigan
10735 Canal, at Dam Number 1, where these three waters co-
mingle?

A. The mean for 49 weeks in 1900 was 233,976. The mean for 52 weeks in 1901 was 277,153. The mean for 52 weeks in 1902 was 294,132. The mean for 26 weeks in 1903, ending June 27th, was 385,475.

ADJOURNED until 11:00 A. M., February 23, 1904.

11:00 A. M., Tuseday, February 23, 1904.

10736 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Mr. Randolph, have you now given the maximum, minimum and mean discharge of the Chicago Drainage Canal, the Illinois and Michigan Canal, and the Desplaines River for the years 1900, 1901, 1902 and 1903, up to July 7.

A. My recollection is that on yesterday I gave the maximum, minimum and mean discharge of our channel. The maximum, minimum and mean discharge of the Desplaines River, but not the maximum, mean and minimum discharge of the combined. I gave the mean discharge of the combined at dam number 1, as I remember it yesterday.

Q. Have you prepared a table showing the pollution at dam number 1, based upon the mean discharge from the drainage canal, the Illinois and Michigan Canal and Desplaines

10737 River, as well as the population discharging sewage, at that point, etc.?

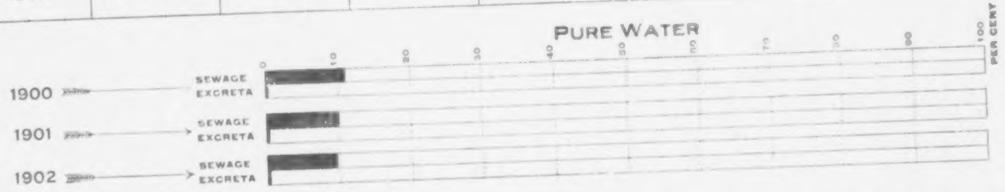
A. I have.

Q. Will you produce and read the table and chart thus prepared in evidence?

A. The table is as follows:

POLLUTION OF SANITARY CANAL BY THE SANITARY DISTRICT.

YEARS	Population discharging Sewage into the Canal	DISCHARGE OF CHANNEL AT DAM NO. 1. IN CU. FT. PER MINUTE FROM WEEKLY AVERAGES			Quantity of Sewage. Gals. per Day same as Water Consumption	Proportion of Sewage to Mean Discharge of Canal	Weight of Urine and Fecal Matter. lbs. per day.	Proportion of Urine and Fecal Matter to Mean Discharge of Canal
		Maximum	Minimum	Mean				
1900	1,443,789	351,088	40,481	233,976	274,209,685	1 : 9.2	3,880,183	1 : 5429
1901	1,494,300	615,392	197,124	277,153	291,391,432	1 : 10.2	4,015,931	1 : 6211
1902	1,545,300	450,328	244,126	295,527	304,386,454	1 : 10.4	4,215,494	1 : 6310



Population of Chicago.

1900	Census..................	1,698,575
1901	Estimate	1,758,000
1902	"	1,818,000
1903	"	1,878,000

Daily Water Consumption of City.

1900..................	322,599,630	gallons.
1901................	342,813,449	"
1902..................	358,101,710	"

Proportion using Drainage Canal.

87% by census of 1890.
84% by school census (1898).
85% estimated 1900 1903.

Weights of Excreta.

Fecal matter 3 oz. per capita.
Urine 40 oz. per capita.

Q. Mr. Randolph, will you explain upon what basis the
10739 table just read in evidence is based, and what the table shows in full?

A. The table applies to the years 1900, 1901 and 1902. It is based upon the population discharging sewage into the drainage canal. The quantity of sewage is determined by taking the per capita of water consumed in the city of Chicago as shown by the reports of the Water Commissioner of the city of Chicago for each of the years mentioned. This is taken as the sewage discharge of the city of Chicago in gallons. This sewage is compared with the mean discharge of water of the combined Illinois and Michigan Canal, the Chicago Sanitary and Ship Canal and the Desplaines River where they come together at dam number 1 in the city of Joliet.

The proportion of sewage based on water consumption is then figured out and shown. The absolute weight of urine and fecal matter contained in this sewage is shown, based upon the testimony of Dr. Ravold and other statistics gathered from other sources. The result of these determinations gives us 3 ounces per day per capita of fecal matter and 40 ounces of urine
10740 per capita per day.

Having determined the total weight of urine and fecal matter, this is compared with the total weight of water discharged in 24 hours from the three sources heretofore mentioned, combining at dam number 1. The determinations and results are shown for each year, in figures. We add to this; these determinations and results are shown graphically in a chart for each year. This chart is divided into a scale of 100 parts. The proportion of sewage is shown in solid black, in the first bar of the chart; the proportion of excreta or fecal matter is shown in the second bar of the chart for each year, and it is also in black.

Q. Upon what do you base the quantity of sewage?

A. The quantity of sewage is based upon the water consumption per capita. The population draining into the canal is multiplied by the number of gallons used per day per capita, to determine the sewage.

Q. Is this table based upon gallons or upon pounds?

A. The sewage is based upon the gallons. The flow through the channel is based upon cubic feet. The weight of the urine and fecal matter is determined by multiplying the number of 10741 inhabitants by 43 ounces and dividing by 16 to get the pounds. The proportion of urine and fecal matter to the water is obtained by multiplying the mean discharge per minute by 1440, which is the number of minutes in 24 hours, and multiplying that by the weight of a cubic foot of water, which is 62½ pounds. So the weight of water thus determined, divided by the weight of urine and fecal matter thus determined, gives you the proportion of urine and fecal matter to the total flow of water.

Q. How many gallons are in a cubic foot?

A. There are 7.48 gallons in a cubic foot.

Q. How many pounds in a gallon?

A. 8.3528 per gallon.

Q. What is the proportion of sewage to the mean discharge of the drainage canal as evidenced by your table for the three years, 1900, 1901 and 1902, respectively?

A. The ratio is 1 to 9.2, either expressed in gallons or cubic feet.

For 1901 the ratio is 1 to 10.2.

For 1902 the ratio is 1 to 10.4.

10742 What are the proportions of urine and fecal matter to the mean discharge of the canal for the three years above mentioned?

A. 1 in 5429 for 1900.

1 in 6211 for 1901.

1 in 6310 for 1902, the comparison being made in pounds.

The table which has just been described is table number 1, and is entitled "Pollution of Sanitary Canal by the Sanitary District."

Q. Have you prepared any other tables?

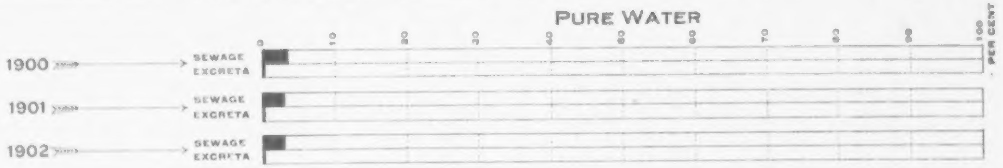
A. Yes sir.

Q. Will you produce and read the table number 2, with a heading "Pollution of Sanitary Canal" in evidence?

A. The table is table number 2 and is marked "Pollution of Sanitary Canal" based on clause on page 12 of the report of the Hydraulic Engineers, and is as follows:

10743 POLLUTION OF SANITARY CANAL. BASED ON CLAUSE ON PAGE 12 OF REPORT OF HYDRAULIC ENGINEERS. See below.

YEARS	Population discharging Sewage into the Canal	DISCHARGE OF CHANNEL AT DAM NO. 1. IN CU. FT. PER MINUTE FROM WEEKLY AVERAGES			Quantity of Sewage based on 60 Gals. per head per day	Proportion of Sewage to Mean Discharge of Canal	Weight of Urine and Fecal Matter. lbs. per day.	Proportion of Urine and Fecal Matter to Mean Discharge of Canal
		Maximum	Minimum	Mean				
1900	1,443,789	351,088	40,481	233,976	86,627,340	1 : 29.1	3,880,183	1 : 5429
1901	1,494,300	615,392	197,124	277,153	89,658,000	1 : 33.3	4,015,931	1 : 6211
1902	1,545,300	450,328	244,126	295,527	92,718,000	1 : 34.3	4,215,494	1 : 6310



The daily quantity of sewage is based on a water consumption of 60 gallons per head per day which the Commission of Hydraulic Engineers reported in 1902 to be all that is necessary.

Page 12 report on the water supply of the City of St. Louis.

"From investigations made upon water systems of cities where the quantity of water used is measured, it appears that in large cities the average volumes needed for domestic, public and manufacturing purposes are respectively, about 30 gallons, 5 gallons and 25 gallons per day for each inhabitant, and that any supply in excess of 60 gallons per day per capita goes to underground leakage or unnecessary waste."

Q. Will you explain upon what data you base this table
10744 and explain its significance?

A. This table differs from the table just described only in the method of determining the amount of sewage per day. The method here used is based upon the clause in the report of the Water Supply of the City of St. Louis, by the Commission of Hydraulic Engineers, 1902, which clause reads as follows:

"From observations made upon water systems of cities where the quantity of water used is measured it appears that in large cities the average volumes needed for domestic, public and manufacturing purposes are respectively about 30 gallons, 5 gallons and 25 gallons per day for each inhabitant and that any supply in excess of 60 gallons per day per capita goes to underground leakage or unnecessary waste."

In this table number 2 the first five columns are identical with table number 1, the first five columns counting from the left. The sixth column gives the quantity of sewage based upon 60 gallons per head per day, and the comparisons thereunder are based upon the substitution of 60 gallons per capita for the gallons per capita used in table number 1. For 1900 the sewage per day was 86.627,340 gallons. The mean discharge, as measured at dam number 1, was, for 1900, 233,976 cubic feet
10745 per minute.

The proportion of sewage to the mean discharge was 1 part in 29.1 parts. That is expressed by measure.

The total weight of urine and fecal matter, in pounds per day, was 3,880,183, and the proportion of urine and fecal matter to the mean discharge of the canal was 1 part in 15,249, expressed in pounds.

These last two divisions are exactly the same as in table number 1, the difference in the table being in the sixth and seventh columns.

In 1901 the mean discharge was 277,153 cubic feet per minute.

The daily sewage discharge was 89,658.000 gallons per day.

The proportion of sewage to mean discharge was 1 to 33 1-3.

The weight of urine and fecal matter in pounds per day was 4,015,931, or 1 part in 6211, expressed in weight.

In 1902 the mean discharge at dam number 1, in cubic feet, was 295,527.

The quantity of sewage per day was 92,718 gallons.

10746 The proportion of sewage to mean discharge was 1 part in 34.3, expressed by measure.

The weight of urine and fecal matter in pounds per day was 4,215,494, or one part in 6310 parts, by weight.

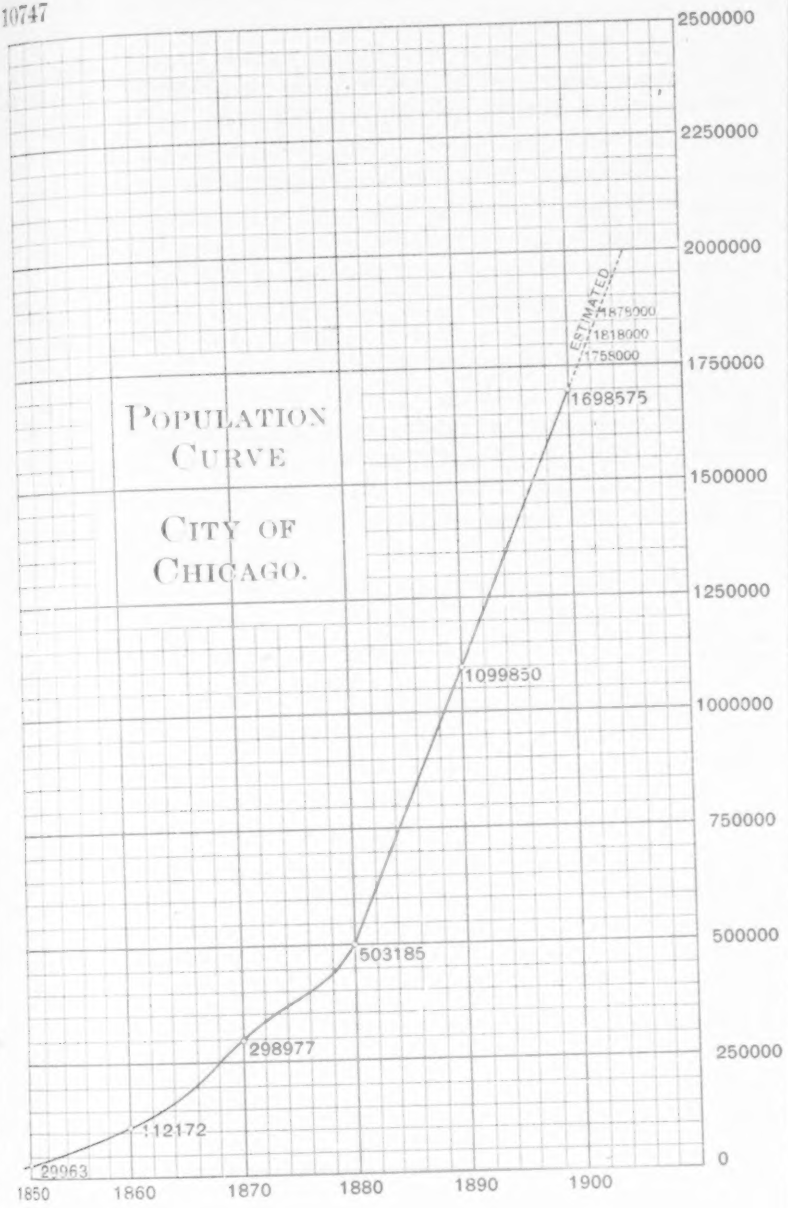
Below the table is a graphic exhibit of the facts set forth in the table. There are two horizontal bars for each year, divided into ten parts, each division representing 10 per cent. In the first bar for each year the sewage is shown in solid black. In the second bar the excreta is shown in solid black, and so for each of the three years covered by the table.

Q. Have you a population curve for the city of Chicago?

A. I have.

Q. Will you produce the chart showing the population curve and make it a part of the evidence?

A. I will. It is number 3 and its title is "Population curve, city of Chicago," and is as follows:



POPULATION CURVE
CITY OF CHICAGO.
2500000
2250000
2000000

112172
29963
1850
1860
1870
1880
1890
1900

Q. Will you explain the principle upon which this curve
10748 is constructed, as just introduced in evidence?

A. This curve is plated upon what is known as cross-section paper, which is divided up into large squares, and each of these large squares divided into ten parts, the lines crossing each other at right angles. Running across the bottom of this sheet, each one of these squares is assigned to a decade, beginning with 1850 and ending with 1910, passing from left to right. Forming up from the plates on the vertical line, each one of these squares represents a population of 250, running up to a population of 2,500,000. For past years the actual population for each year is dotted upon the vertical line, corresponding to population. All of these dots are joined by a line which a part of the time is undulating, but from 1880 to 1900 is practically straight, very little deviation from a straight line.

From 1900, the line is continued practically straight, showing the census year by year. This line is called the curve of population, and for any year you can ascertain what the population was by looking that year on the bottom of the map,
10749 following the line which corresponds to that year up vertically until it intersects the line of poulation curve, then following the horizontal line from this point of intersecton to the figures indicated on the right of the map, and ascertain what the population was for that year.

Q. Have you prepared a table of the population of Chicago?

A. I have. It is marked Number 4. Its caption is "Population of Chicago."

Q. Will you produce and read the table thus prepared in evidence?

A. The table is produced, and is as follows:

10750

POPULATION OF CHICAGO.

Census 1900.

1902 304,386,454	211,379	28,259

Q. Will you explain the table just introduced?

10751 A. The figures shown under the head of "Census" in the upper left hand corner of the sheet, give the census of 1900, of the city of Chicago, by wards, from ward number 1 to ward number 35, the resulting total is put at the foot of the column. On the right of this census for 1900 are given the successive reports of the census Bureau for the sixty years from 1840 to 1900, inclusive.

Following the data there given the population for the years 1901, 1902 and 1903 are given, and given as taken from the curve of population just described. Beneath the data just described is a statement of the proportion of poulation, discharging into the drainage canal, derived from the Federal Census of 1890, and the school census of 1890, and our estimate of the present time. Then below that comes a further statement for the year 1900, the year 1901 and the year 1902. This information as to population occupies the upper half of the sheet.

Following this is a report of the consumption of water by the city of Chicago for the years 1900, 1901 and 1902. This total consumption per diem is derived from the popu-

10752 lation and the daily consumption per capita is thus determined.

Following this data is an exhibit of the population of the district draining into the channel, measured by the gallons per capita of water consumed to determine the gallons of sewage.

Next follows a statement showing the gallons of sewage per day, the gallons per minute and the cubic feet per minute for the years 1900, 1901 and 1902.

Q. What percentage of population of the district drained into the drainage canal in 1900, 1901 and 1902?

A. Eighty-five per cent.

Q. What was the per capita consumption of water in the city of Chicago in 1900, 1901 and 1902, respectively?

A. The daily consumption per capita for 1900, 190 gallons.

For 1901 was 195 gallons.

For 1902 was 197 gallons.

ADJOURNED UNTIL 2:00 P. M., same day.

2:00 P. M., Tuesday, February 23, 1904.

10753 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH

resumed the stand for further direct-examination by Mr. Todd, and testified as follows:

Q. Have you prepared a table under the caption of "Excreta"?

A. Yes sir.

Q. Will you please produce and read the table into the record?

A. Yes sir, the table is as follows:

10754

EXCRETA.

*Excreta from 100,000 persons per year—

37,610	Men	4,521,664 lbs. Feces	45,217,782 lbs. Urine.
34,630	Women	1,237,040 " "	37,458,512 " "
14,060	Boys	1,239,504 " "	6,423,670 " "
13,700	Girls	274,736 " "	5,041,344 " "
		7,272,944 " "	94,141,308 " "

Daily per capita................	3.2 oz. Feces	41.3 oz. Urine.
†From another..................	2.91 oz. "	34.1 oz. "
From Dr. Ravold..........	3.00 oz. "	40. oz. "

Assume a total of 43 oz. of Excreta.

Total weight of Excreta per day.		Lbs. per minute.
1900............	1,443,789×43 oz.=3,880,183 lbs.	2,694
1901............	1,494,300×43 oz.=4,015,931 lbs.	2,789
1902	1,545,300×43 oz.=4,215,494 lbs.	2,927

Discharge at Dam No 1.		*Proportion of Excreta to Discharge.*
1900..	233,976 Cu.	1 to Ft.=14,623,500÷2,694=5,429
1901..	277,153 Cu.	1 to Ft.=17,322,062÷2,789=6,211
1902	....295,527 Cu.	1 to Ft.=18,470,437÷2,927=6,310

Discharge at Dam No. 1.		*Cu. Ft. Sewage.*	*Proportion of Sewage to Discharge.*
1900..........	233,976 Cu. Ft.	25,458	1 to 9.2
1901..........	277,153 Cu. Ft.	27,053	1 to 10.2
1092	295,527 Cu. Ft.	28,250	1 to 10.4

*First report of Rivers Polluting Commission of Great Britain, page 27. From the Researches of Wolff and Lehman.

†Page 156. Sewage Disposal in the United States. Rafter and Baker.

Q. Will you explain the table that you have just introduced and what it purports to show? 10755

A. It purports to show the amount of excreta from 100,000 persons per year. The first seven lines of this table are taken from the report of the Rivers Pollution Commission of Great Britain, page 27, from the researches of Woolf and Lehman, which give the excreta of 37,610 men, 34,630 women, 14,060 boys, and 13,700 girls, giving the pounds of feces and pounds of urine and as a result they got the average feces of 3.2 ounces and the average urine of 41.3 ounces.

Then another source is page 156 of Sewage Disposal in the United States, Rafter and Baker. They give the average for feces of 2.91 ounces and the average for urine of 34.1 ounces.

Dr. Ravold in his testimony which I heard in St. Louis gave 3 ounces of feces and 40 ounces of urine, and it is the data that I have used in making all of my computations.

Following this on the assumption of 43 ounces of excreta per capita, and taking the population discharging into the sanitary canal, multiplied by 43 ounces we get the results which I have read in the tables heretofore. 10756

The next item of information is the discharge of dam number 1 and it simply gives the process of arriving at that proportion that was used in all the tables. By the two methods one giving the theoretical volume of sewage as shown by the water supply of the city of Chicago, and the other actually as based upon 60 gallons per capita.

Q. Have you a table showing the pollution of the Illinois River prepared under your direction and supervision, Mr. Randolph?

A. Yes sir.

Q. Will you produce and read the table into evidence?

A. Yes sir, the table is as follows:

10757 POLLUTION OF ILLINOIS RIVER.

Drainage basins.	Area square miles.	Population (census) 1900.	Urban Pop., towns of 1,000 and over. 1900.	Estimated water supply, gallons per capita per day.	Estimated total gallons water supplied per day, 1,000 gallons.	Cu. Ft. per second.

Discharge of Illinois river at Kampsville Oct. 20, 1891 (U. S. Engrs.).........1452.7 C. F. S.

" of Illinois and Michigan Canal.. 600.0 "

Natural discharge of river at Kampsville Oct 20, 1891................ .... 852.7 "

Add for basin of Macoupin creek........................ .... 147.3 "

Natural discharge of the Illinois river Oct. 20, 1891.................. .... 1000.0 C. F. S.

Sewage produced by urban population, 85.72 Cu. Ft. Sec., or 57.19 C. F. S., when reduced to a basis of 60 gallons per head per day.

1000÷57.19=17.48 Pollution=1:17.48 as against Drainage Canal Pollution of 1:34.3.

Q. Will you describe the table just read and what it 10758 purports to show?

A. The caption of the table just read is Pollution of the Illinois River. It is divided into seven spaces:

The first space is headed Drainage Basins.

The second space is headed Area in Square Miles.

The third space is population, census of 1900.

The fourth space is Urban Population, towns of 1,000 and over for 1900.

The fifth space is Water Supply in Gallons per capita per day.

The sixth space is the estimated total gallons of a water supply per day.

The last space is the cubic feet per second.

The first drainage basin is the Desplaines, 1758 square miles.

The population is 124,855.

The urban population 70,748.

Water supply in gallons per day per capita 99.3.

Estimated total gallons water supply per day 7,025,000.

10759 The seventh column is cubic feet per second 10.86.

For the DuPage we have not the drainage area.

The population is 21,704.

Urban population is 6,851.

Water supply gallons per capita per day 23.1 gallons.

The water supplied per day 158,000 gallons.

Cubic feet per second .24 of 1 cubic foot.

The explanation given with reference to the Desplaines water shed and the DuPage applies to the Fox, the Vermillion, the Mackinaw, the Spoon, the Sangamon, the Crooked, the McKee, Macoupin and the Illinois, and the last name in the first column is the Peoria industries. For those industries there is no area given, no population, no water supply per capita, but the 1,000 gallons which amounts in this instance to fifteen thousand thousands or 15,000,000 gallons and the cubic feet per second is 23.11. The poulation in all the drainage areas covered in this table amounts to 1,511,387.

The urban population 617,664.

The average water per capita 65.7.

And the total per day 55,614,000 gallons.

The cubic feet per second 85.72.

Following the tables is a statement giving discharges at 10760 various points.

The first gives the discharge of the Illinois River at Kampsville, October 20, 1891 (U. S. Engineers) 1452.7 cubic feet per second.

Discharge of the Illinois and Michigan Canal 600 cubic feet per second.

Subtracting the discharge for the Illinois and Michigan Canal from the report of the discharge given by the United States Engineers giving the natural discharge for Kampsville, for October, 1891, as 852.7 per second.

The discharge from the Macoupin creek must be added. 147.3 cubic feet per second, making a total annual discharge of the Illinois River October 20, 1891, of 1,000 cubic feet per second.

The sewage produced by urban population 85.72 cubic feet per second.

10761 A. Sewage produced by urban population 62.63 cubic feet per second or 57.19 cubic feet per second when reduced to a basis of 60 gallons per head per day; taking 1,000 cubic feet per second as the natural flow at Kampsville and dividing that by 57.19 cubic feet per second, we get, as the result, 17.48 or a pollution of 1 in 17.48 as against the drainage canal pollution of 1 in 34.3.

Q. From the tables which you have introduced, what conclusions do you draw from those tables?

A. I conclude that the natural pollution of the Illinois River is due to the urban and rural population draining into its water shed, exclusive of all sewage coming from Chicago, is more polluted than the waters of the Illinois River are when combined with the discharge from the sanitary canal after the opening of said canal. In the conditions which obtain without considering the discharge from the sanitary canal the pollution is 1 in 17.48. The pollution, considering the sanitary canal, is 1 in 34.3.

Q. Measured in what?

10762 A. In quantity.

Q. Mr. Randolph, have you a map showing the various water sheds of the Illinois River from Chicago to Grafton?

A. Yes sir, I have.

Q. Will you please produce the map?

A. I will.

Q. Is this a correct map of the various water sheds of the Illinois River from Chicago to Grafton?

A. It is essentially correct. It is made up from the best data obtainable from the various sources that we have sought.

Q. Was this map made under your direction and supervision in the office of the Sanitary District of Chicago?

A. It was.

Q. How are the different water sheds indicated on this map?

A. They are indicated by different colors and dotted lines to indicate the summit of the divide between different water sheds. The map shows the number of square miles in each water shed.

Q. Are all the cities and town on the Illinois River located on this map?

10763 A. All the important towns are shown on the map.

Mr. Todd: I offer this map which is known as the Sanitary District of Chicago Map of the Illinois River water sheds scale 4 miles to an inch, and ask to have it marked defendants' Randolph's Exhibit B.

Which map is so marked by the Commissioner.

10764 Q. Will you please state whether the Sanitary District of Chicago is laid out on the map that has just been introduced in evidence?

A. Yes sir, the sanitary district of Chicago is shown on the southwest side of the area marked "Lake Michigan." The general outlines are indicated by heavy border lines and the wording "Sanitary District of Chicago" appear within those borders.

Q. Are you acquainted with the Desplaines River and the Illinois River from Lockport to Grafton?

A. I am.

Q. What opportunities have you had for acquainting yourself with the physical conditions of these streams?

A. I have an intimate knowledge with the Desplaines River growing out of frequent passages up and down the stream from Riverside to the junction of the Desplaines and Kankakee. I have never followed the Illinois River continuously through to
LaSalle, but I have traveled in sight of it and have been
10765 to many points along that river between the mouth of the
Kankakee and La Salle. From La Salle through to the mouth of the Illinois River I have made the trip by boat upon two or more occasions.

Q. What are the physical characteristics of the Desplaines River?

A. The Desplaines River is one of fluctuating volume. In certain seasons of the year it is almost dry. In other seasons of the year it is a stream carrying very large volumes of water, the maximum volume of which I have information being 800,000 cubic feet per minute. The fall of the stream for a distance of about 27 miles southwest from Chicago is slight. The grade is very slight. When it reaches Romeo the valley drops off rapidly and the stream, which follows the trough of the valley, flows very rapidly.

From the controlling works at Lockport to the upper basin at Joliet it has a fall of about 30 feet—the fall in the stream itself is about 30 feet, and at Lockport it enters the basin formed by dam number 1. Passing over that dam it enters a large channel made by the sanitary district and falls quite rapidly to Lake Joliet.

10766 Q. What towns lie tributary to the Desplaines River above Lockport, draining directly into that stream?

A. Since the diversion of the Desplaines River made by the sanitary district in 1893 there is no town draining into the Desplanes between Lyons and Lockport. The Sanitary District canal lies between the towns in the valley and the Desplaines River. Riverside drains into it. Grossdale drains into it, through Salt Creek. The population of Riverside is about 1600. Then the next town draining into it is Maywood on the west, and River Forrest on the east. Then the next town of any consequence is Desplaines.

Q. After leaving Joliet will you describe the physical characteristics of the Desplaines River?

A. There is a rapid fall in the channel from dam number 1 to the head of Lake Joliet, which is about 3½ miles southwesterly of dam number 1. The fall in that distance is approximately 21 feet. Lake Joliet is a widening of the stream and is probably a half a mile wide, and something like five miles long. There is a very slight fall from the head of Lake Joliet which is practically Brandon's road through to the head of Treat's
10767 Island.

For the distance of about a mile from Treat's Island there is a fall of nearly ten feet; from there the fall is gradual until you reach the pool made by the Marseilles dam. The water is backed up by the Marseilles dam for somewhere in the neighborhood of twenty miles. The fall at Marseilles is about 12 feet. At Ottawa, about 8 miles from Marseilles, the Fox River empties into the Illinois and the fall is gradual from there to Peru. Peru is the end of the Illinois and Michigan Canal and is at the head of the back water in Henry dam. The Henry dam is 540 feet long and six and one-half feet high. That backs up 29 miles. The length of that pool is 29 miles.

At Henry there is a lock 75 feet wide and 325 feet long. From the Copperas Creek dam to Henry dam is 59 miles and the back water from Copperas Creek is felt as far back as Henry. Between Henry and Copperas Creek the river forms Lake Peoria, a shallow lake of varying width, probably an average width of a mile and three-quarters, and 8 or 10 miles long, simply an enlargement of the Illinois River.

The next dam after passing Copperas Creek is at La Grange. Its pool is 58 miles long. The back water extends back to Copperas Creek. The height of the dam at La Grange is 7.33 feet, and its width is 818½ feet. The length of the Copperas Creek dam is 640 feet.
10768 From La Grange to Kampsville is 48 miles and that is the last of the dams in the Illinois River. The La Grange and Kampsville dams were built by the United States Government. The width of the Kampsville dam is 1200 feet and its height 7.3. From Kampsville it is 31 miles to the Mississippi River.

Q. Mr. Randolph, prior to the opening of the drainage canal what was the character of the water that went south in the

Illinois and Michigan Canal, by the Bridgeport pumping works?

A. It was water in a highly polluted state.

Q. When did those pumps begin to pump the sewage of the Chicago River into the Illinois and Michigan Canal?

A. The pumps were installed, that is the set of pumps were put in after the deepening of the canal. The canal was deepened between 1865 and 1871 and the flow was only about 9,000 cubic feet per minute. It was insufficient for the sewage and the pumps were put in the latter part of 1884. The operation was commenced about the end of the year 1884.

Mr. Jeffries: I move to strike out the answer and question as immaterial.

10769 Mr. Todd: I offer in evidence an act to provide for the completion of the Illinois and Michigan Canal upon the plan adopted by the state in 1836, approved February 16, 1865, published in the public laws of the State of Illinois in 1865, pages 83 to 84, which is set out in exhibit in the answer to the bill of complainant, filed by the State of Missouri.

Mr. Jeffries: Without objecting to the formality of the proof or the authenticity of the statute in question, I object to the introduction of the statute for the reason that it has no bearing upon the issues involved in this case and constitutes no justification upon the part of defendant, of the Sanitary District of Chicago, committing the nuisance set up in complainant's bill, and for that reason is incompetent, irrelevant and immaterial.

It is agreed that the statute as set out in Exhibit A in the answer of the defendant Sanitary District of Chicago shall be referred to and treated as evidence, subject to the objection presented.

Q. From 1884 to 1900 what was the average volume of sewage pumped from the Chicago River into the Illinois and Michigan Canal? 10770

Mr. Jeffries: Objected to as immaterial.

A. Approximately 50,000 cubic feet per minute.

Q. After this sewage was pumped into the Illinois and Michigan Canal where did it go?

Mr. Jeffries: Objected to for the reason that it is immaterial, and for the further reason that the evidence on the part of the defendants shows that the disease producing organisms more rapidly disappeared in their raw state as contained and existed in the Chicago River prior to the opening of the canal than they do in the drainage canal since its opening by the addition of 250,000 cubic feet of water per minute from Lake Michigan.

Q. Question repeated.

A. It flowed through that canal to Lockport where a portion of it was discharged into the Desplaines River over a waste weir or else passed through the wheels of the water power at that point. What did not enter the river at this point entered it after the Desplaines River reached what is known as the upper basin at Joliet. The complete mingling was in the basin at Joliet.

Q. Have you prepared a map or chart showing the population on the water sheds of the Illinois River, the Mississippi River and the Missouri River above St. Louis? 10771

A. I have.

Q. From what was this data prepared, Mr. Randolph?

A. It was made up from maps of the states through which these rivers flow. The populations were gotten from the Century Atlas, in towns of 500 or over.

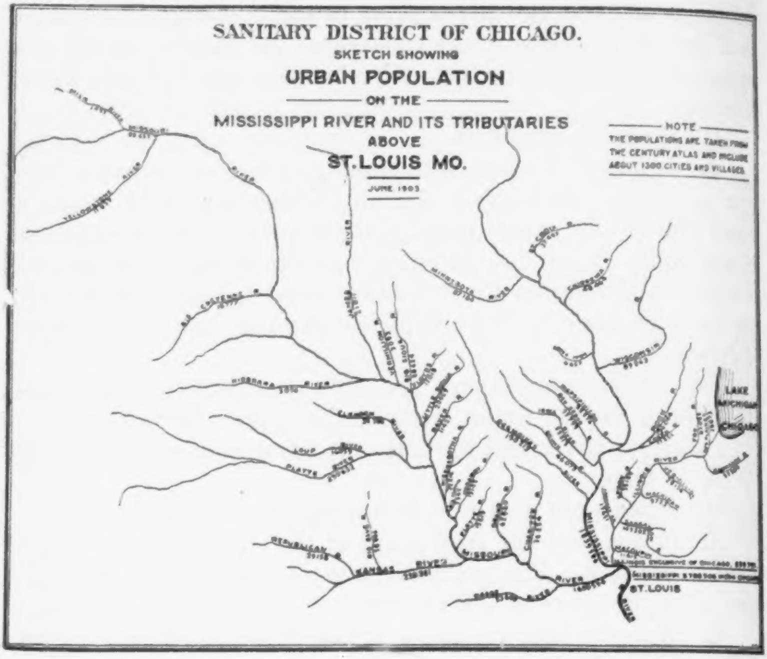
Q. Will you produce this chart or map and make it a part of the evidence?

A. I will.

Mr. Jeffries: I object to the introduction of the map or chart because it is irrelevant and not competent evidence.

A. The chart or map is as follows:

10772



SANITARY DISTRICT OF CHICAGO.
SKETCH SHOWING
URBAN POPULATION
ON THE
MISSISSIPPI RIVER AND ITS TRIBUTARIES
ABOVE
ST. LOUIS MO.
JUNE 1903
NOTE
THE POPULATIONS ARE TAKEN FROM THE CENTURY ATLAS AND INCLUDE ABOUT 1300 CITIES AND VILLAGES.
LAKE MICHIGAN
CHICAGO
MISSOURI
KANSAS
RIVER
ST. LOUIS

10773 Q. From the map that you have introduced, the poulation of the Illinois River, exclusive of Chicago, as evidenced by this map, is what?

A. 599,751.

Q. What is the poulation of the Mississippi River above Grafton?

A. 1,839,586.

Q. What is the population of the Missouri River above its mouth?

A. 1,650,594.

Q. What is the population lying tributary to the Mississippi River upon the three water sheds above St. Louis, including Chicago?

A. 5,788,506.

Q. What is the population on the Illinois River above

Grafton, including the sanitary district of Chicago, as shown by the map just introduced?

A. The population of the Illinois River, including Chicago gives 2,298,326. Substracting the Illinois River from that gives 1,698,575 for the Sanitary District.

ADJOURNED UNTIL 10:00 A. M., February 24, 1904.

10774 10:00 A. M., Wednesday, February 24, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Mr. Randolph, have you the gauge readings of the Desplaines River at Lockport, and the Illinois River at Peru, which were asked of you by Professor Van Ornum in a letter, the reply to which was read into evidence in this case, by Professor Van Ornum?

A. I have.

Q. In what way have you those gauge readings?

A. At Lockport I have the daily readings for the month of March and for the whole period since we began flowing water over the Bear Trap Dam, but I suppose it would be sufficient for your purpose to take the mean weekly readings?

Q. Have you the weekly average?

A. I have.

10775 Q. Will you read the weekly averages of the gauge readings at Lockport in the Desplaines River, for the period that you have the data for?

A. The period that he asked for was the month of March, 1903. The weekly average for the first week ending March 7th was —4.74.

Q. What do you mean by minus?

A. I mean that he asked for the gauge reading—that shows the elevation of the water on the gauge, that without having a discharge curve—that gives you no idea of the volume of water flowing at that time. He probably had the discharge curve so that he knew what he wanted it to apply to.

For the week ending March 14th the weekly average was −2.915 feet.

For the week ending March 21st, the average was −2.427.

For the week ending March 28th the average was −2.575.

For the week ending April 4th the weekly average was −2.121.

That covers the period asked for.

10776 Q. Will you give the gauge readings at Peru for the period requested in that letter?

A. I will give the gauge readings as shown upon the gauge records returned to us from that point, which are as follows:

I will preface this statement by saying that the gauge is a little nearer LaSalle than it is Peru, and in our records it is referred to as the LaSalle gauge. The weekly means have not been worked up, but the daily means from March 12th to 25th have been worked up and I will give those.

March 12th the mean for the day was 127.75.

This 127.75 is referred to Chicago datum, and means that that is 127.75 feet below Chicago datum.

	March 13th	128.04
	March 14th	128.42
	March 15th	128.83
	March 16th	129.33
	March 17th	129.73
	March 18th	130.20
10777	March 19th	130.38
	March 20th	129.30
	March 21st	128.68
	March 22nd	128.98
	March 23rd	129.43
	March 24th	129.50
	March 25th	130.28

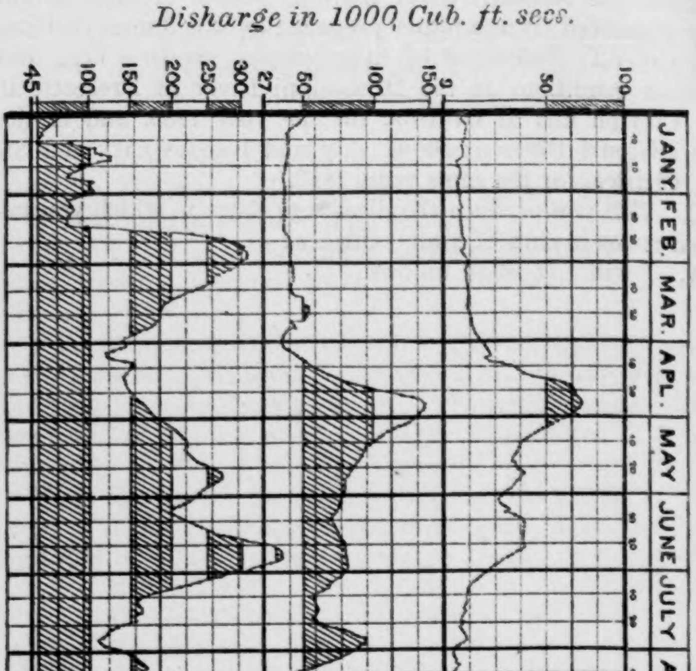
This apparently carried the readings through the flood period. The next record reading is on March 29th, 131.90, and on April 1st, 133.04.

Q. Will you give the volume of flow of the Illinois River at Kampsville, the Mississippi River above Grafton, the Missouri River above its mouth, and the Mississippi River at St. Louis?

A. In determining the volume of flow in the Mississippi River and the Missouri River the only source of information I have is derived from a paper prepared by Mr. James Seddon, which paper is illustrated by hydrographs, showing high and low water conditions in the Mississippi River at Prescott, at Clayton and at Grafton, for the year 1883, and in the 10778 Missouri River at Sioux City and Kansas City and St. Charles, for the same year, 1883.

Q. Will you produce the discharge chart to which you refer and make it part of your evidence?

A. I will. It is as follows:



FLOOD REGIMEN OF THE UPPER MISSISSIPPI

1883

10779 Q. Will you explain that chart and what it represents?

A. The caption of this chart is "Flood Regimen of the Upper Mississippi, 1883." The chart itself is divided vertically and horizontally into squares. The horizontal lines on the left indicate the number of thousands of cubic feet of water flowing, corresponding to the water heights which are shown on the right. The vertical lines indicate the months and the days of the months. Three spaces are alloted to each month beginning with January, 1883. Each space stands for ten days.

With the water at zero at Grafton there was forty-five thousands cubic feet per second flowing. The flood elevations, as before stated, are indicated by the figures on the right and the corresponding flood volumes are indicated by the figures on the left and the intersection of the vertical lines with the lines and depth, connected by broken lines, show the profile of the flood.

With a 4 foot stage at Grafton there was about ninety-eight thousands of cubic feet of water flowing per second. With the water at a 10 foot stage there was one hundred and ninety thousands cubic feet per second flowing. The lines indicating the flood profile which show the dates upon which this
10780 height or these heights occur by their crossing of the date
line. The maximum height of the water for the year 1883 was reached about June 25th, and the minimum about December 28th.

The chart for the Missouri River is constructed in the manner before described.

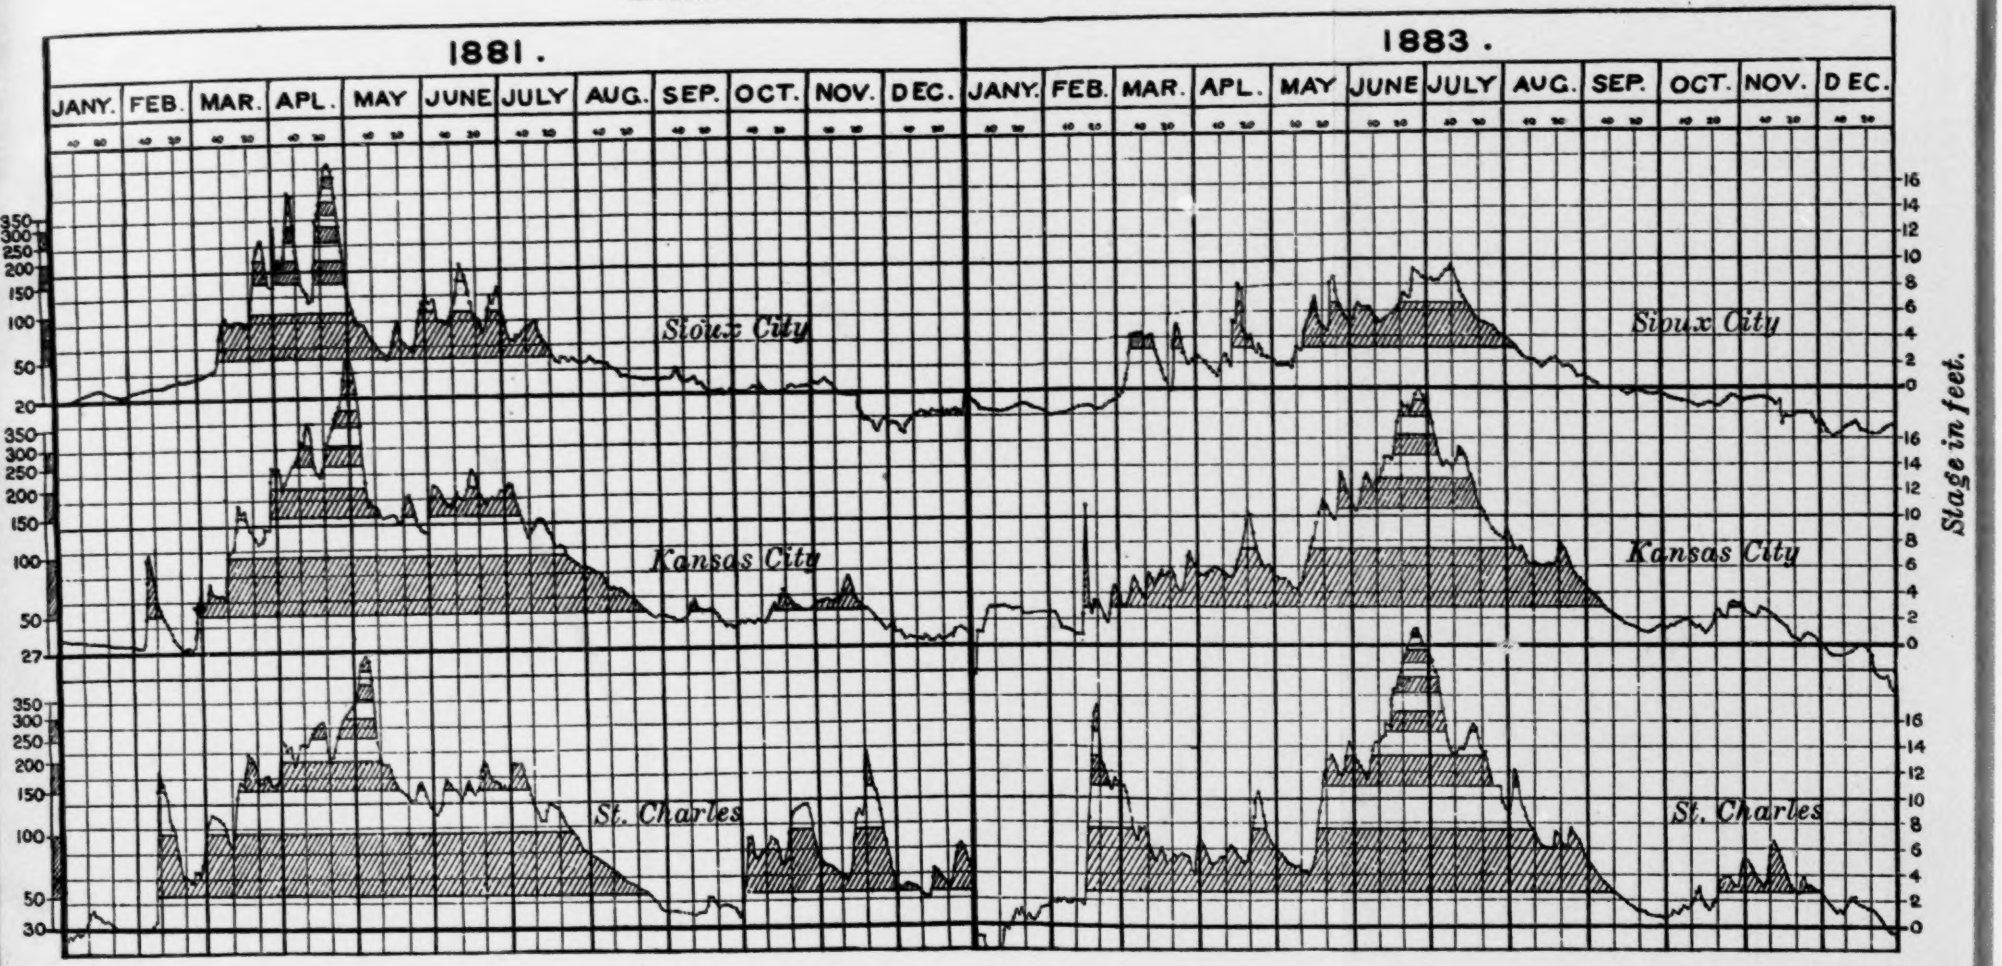
Q. I will ask you if you have a chart of the Missouri River?

A. I have.

Q. Will you produce and make a part of the evidence the chart to which you refer?

A. I will. It is as follows:

EXTREME FLOOD REGIMENS OF THE MISSOURI



10782 Q. Will you describe the chart just introduced?

A. The caption of this chart is Extreme Flood Regimen of the Missouri. It covers the years 1881 and 1883, respectively. This chart is constructed in the same manner as the chart previously described, for the Mississippi River. It gives the flood conditions at three points, Sioux City, Kansas City and St. Charles.

I have also a chart showing the flood combinations in the Mississippi River at three points, St. Louis, Paducah and Cairo. This chart is as follows:

FLOOD COMBINATIONS

St. Louis and Paducah equals Cairo

10784 It also gives conditions in the Ohio River and in the lower Mississippi.

The caption of this chart is Flood Combinations, St. Louis and Paducah Equals Cairo. It covers the years 1881 and 1882, for St. Louis, Paducah and Cairo, and the years 1883 and 1884 for the middle Mississippi, the Ohio and the lower Mississippi. The flood volumes at St. Louis equal the combined flow of the Mississippi and the Missouri Rivers.

The period covered is October, November and December of 1881 and from January to September, inclusive, of 1882, for St. Louis.

Q. Have you any measurements showing the volume of flow at Peoria?

A. I have several discharge measurements made for the Division of Hydrography, United States Government by one of my own assistants.

Q. Will you give the flow measurements at Peoria, for the period that you have given the dates and the flow?

A. The first discharge reading is March 18, 1903, observation made by E. H. Heilborn, area or cross section 10785 15376.3 square feet. Mean velocity 2.62 feet. Discharge 41218.7 per second.

April 3, 1903, observation made by E. H. Heilborn, area of cross-section 13713.02 square feet. Mean velocity 1.88 feet per second. Discharge 25839.4 feet per second.

April 29, 1903, measurement made by E. H. Heilborn, total area 13712.4 square feet. Mean velocity 1.9 feet. Discharge 26078.8 feet per second.

Observation May 13, 1903, E. H. Heilborn, total area 11072.5 square feet. Mean velocity 1.39 feet per second. Discharge 15337.5 feet per second.

July 5, 1903, E. H. Heilborn, area of cross-section 7768. Mean velocity 1.18 feet per second. Discharge 9424 feet per second.

August 22, 1903, measurements made by E. H. Johnson, area of cross-section 7218. Mean velocity 1.20 feet per second. Discharge 8713 feet per second.

January 30, 1904, E. H. Heilborn, area of cross-section 14874.8 square feet. Mean velocity 1.58 feet per second. Discharge 21124.1 feet per second.

February 14, 1904, E. H. Heilborn. Gauge height was
10786 15.42 on the Peoria gauge. I have not the reference to
Chicago datum. The total area of cross-section was
13639.2 square feet. The mean velocity was 1.2 feet per second and the discharge was 16305.1 feet per second.

February 14, 1904, E. H. Heilborn, area of cross-section 14814.9 square feet. Mean velocity 1.5 feet per second. Discharge 21783.7 feet.

Q. Have you the volume of flow at Kampsville?

A. I have information prepared by Major W. L. Marshall. At the time these observations were made he was Captain Marshall and was in charge of the Illinois river improvements for the United States government.

The first observation which he reports is April 10, 1889, gauge reading 4 feet; area of cross-section 7312 sq. feet. Mean velocity 1.4 feet per second. Cubic feet flow per second 10275.

On April 9th he observes the gauge reading as 4.2, the cross-section 7345, the mean velocity 1.37 feet per second. The volume of discharge 10052 cubic feet.

On April 1st he gives the gauge reading as 4.6, area
10787 of cross-section 7770, mean velocity 1.48, volume of dis-
charge 11548 feet per second.

On July 11th the gauge reading of 7.5 feet; area of cross-section 10859 square feet velocity of flow 2.2 feet per second; volume of flow 23892 cubic feet per second.

June 21st, gauge reading 9 feet; area of cross-section 12901 square feet; velocity in feet per second 2.41; volume of discharge 31068 cubic feet.

One June 22nd gauge reading 9.2 feet; area of cross-section 13084 square feet; mean velocity 2.43 feet per second volume of discharge 31855 cubic feet per second.

Then, he has a note here showing that on May 31st of that year the gauge read 10.5 feet, but it was affected by back water from the Mississippi. The cross-section at that date was 14516 square feet. The velocity was 1.47 feet per second, and the volume of discharge only 21344 cubic feet per second.

For January 18, 1900, he gives the gauge reading at Kampsville 12.8. That is a local gauge. The area of cross-section
is 13069 square feet. The mean velocity in feet per
10788 second 2.55, the resulting volume 33295 cubic feet.

In 1891 we have October 18th gauge reading 00.2; area of cross-section 2321 square feet; velocity per second .81 feet; volume of discharge 1878 cubic feet.

On October 20th the gauge read as above—.2 feet, that is, .2 feet below zero. The area of the cross-section 2224 square feet; the velocity .65 feet per second. The volume mean discharge 1453 cubic feet.

On the same day the same gauge reading he gets a cross-section of 2245 square feet and a velocity of .67 feet, volume of discharge 1505 cubic feet, found in report of Captain W. L. Marshall, for 1889 and 1890 in the report of the Chief of Engineers for 1890, page 2443; report of Captain W. L. Marshall for 1891 in the report of Chief of Engineers for 1892, pages 2263-6.

Q. Have you a profile of the water way from Lake Michigan to Cairo?

A. I have.

Q. Where was it prepared?

A. It was prepared in my office.

10789 Q. Will you produce and make it part of your evidence?

A. I will. Its title is "Profile of Waterway from Lake Michigan to Cairo," and is as follows:

PROFILE
OF
WATER WAY
FROM
LAKE MICHIGAN TO CAIRO.

10791 Q. Will you explain briefly the plan upon which this profile is made and particularly describe whether the dams in the Illinois river are shown upon the profile?

A. The profile is constructed in the usual manner, the vertical scale being very much exaggerated. It indicates by a broken line the bed of the channel from the best data which we have been able to obtain and where the hydraulic gauge line is not regulated by dams it is shown by a wavy black line.

The pools made by the dams are indicated by straight lines, slightly descending. This profile commences at Lake Michigan, follows the course of the Chicago river and the drainage canal through to Lockport and thence on through the Desplaines, the Illinois and Mississippi rivers to Cairo.

Q. Mr. Randolph, did you calculate the distance between Chicago and St. Louis, as to the velocity of flow between those two points?

A. No, sir, it was done for me by my assistant, Mr. Crane. He prepared the table for me.

Q. What means were employed by you for ascertaining the velocity from Chicago to St. Louis?

A. Floats were used from Lake street to Robey street.
10792 The floats used in this stage of the work were wooden balls, a few of the wooden balls were put in the river at Lake street and allowed to float down to Robey street, a man following in a boat and the time of those balls is what is given in this table.

From Robey street to Lockport the cross-section of the different stretches of the channel being known, and the volume of flow being known, the velocity was easily computed, so for that 28 miles flow measures were not used, because we had a more accurate method of arriving at it, which is by taking the volume of flow as compared with the cross-section. From Lockport to St. Louis floats were used. The floats were of the same general character as complainant's Exhibit 43, except that in place of a 4-flange weight we had a hollow cylinder, suspended by a picture wire from the float.

The float itself was composed of two segments of a sphere, put together, looking like the two tops of a tin pail put together with the convex sides out, with a place on the top side for a flag, and a picture wire attached to the bottom side, the object being to present as little surface to the wind as possible. The flag was pivotal and free to adjust itself to the wind. The floats 10793 were followed by my assistants. For part of the distance they had to follow it on shore because a boat could not get through the rapids, but when it was practicable to follow it in a boat they followed it in the boat, and they were kept going night and day except on such occasions as accident of any kind stopping the work, and they were then taken out and the time noted. Through the rapids wooden balls were substituted for the floats above described, and whenever it was practicable to follow in a boat they were followed in a boat, and the observations were continued night and day, except in case of accident or storm, when the float was taken out, the place noted, and the time noted, and when work was resumed they were put in at the same place and the timing begun from the time of restoration.

Q. Will you produce and read in evidence the table which was prepared as a result of this experiment?

A. I will; the table is as follows:

	Interval.			Corrected Interval.			Total Time.			Total Time.
10794	Days	Hours	Minutes	Days	Hours	Minutes	Days	Hours	Minutes	Days
Lake St. to Robey St.	0	5	30	0	6	52	0	6	52	.3
Summit	0	5	42		5	42	0	12	32	.5
Willow Springs		7	22		7	22	0	19	54	.8
Controlling Works		18	54		18	54	1	14	48	1.6
Joliet		1	58		2	28	1	17	16	1.7
Lake Joliet		1	24		1	45	1	19	1	1.8
Through Lake Joliet		2	15		2	49	1	21	50	1.9

Eads Bridge			58		1	10	18	11	40	18.5

10795 Q. Will you describe the table just introduced in evidence, and the method employed in its preparation?

A. This table consists of five columns. The first column gives the names of the places passed by the floats. The second column gives the time of passage between points. The third column gives this interval of passage corrected. The fourth column gives the correct total distance traveled by the float, in days, hours and minutes. The fifth column gives the time in days and fractions of a day. The second column of which I have spoken gives the actual observed time of the passage of the float. This time shows practically the surface velocity of the stream. The mean velocity is taken as 0.8 of the surface velocity and the corrections are made upon the basis of .8 of the surface velocity.

Q. What was the mean time from Lake street in the city of Chicago to the Eads bridge at St. Louis?

A. Eighteen days and a half. The term "mean time," as given here applies to the total time consumed in this experiment, from Lake street, Chicago, to the Eads bridge, St. Louis, as corrected in the manner heretofore explained. The correction made is taking .8 of the apparent velocity as the true velocity.

10796 Q. What were the stages of the river at the time this experiment was made?

A. I can hardly call it the mean stage of the river. It was not a flood time, that is, not anything like a maximum flood, nor was it a low water. It was a full river but not a flood.

Q. Was it above or below the mean average flow of the river ?

A. I think it was above the mean average flow of the river.

Q. Will you read the gauges of the river at the time this experiment was made?

A. I have here the gauge readings taken at LaSalle and at Grafton, upon the same days. On July 15th the gauge at La-Salle—the gauges are taken there mornings and evenings, but the averages not worked up, but the variation is so little that I take the afternoon gauges at 5 p. m. The 5:00 p. m. gauge at LaSalle reads as follows:

July 15th,	139.6,	below Chicago datum.
On the 16th,	139.7	
On the 17th,	139.8	
On the 18th,	138.65	
On the 19th,	138.20	
On the 20th,	138.40	
10797 On the 21st,	138.85	
On the 22nd,	139.1	
On the 23rd,	139.55	
On the 24th,	139.5	
On the 25th,	139.65.	

The readings at Grafton are taken from the United States Gauge Reader.

July 14th,	8.55	That is a local gauge.
On the 15th,	9.6	
On the 16th,	10.5	A rising stage of the river.
On the 17th,	11.3	
On the 18th,	12.1	
On the 19th,	12.5	
On the 20th,	12.6	
On the 21st,	12.7	
On the 22nd,	12.7	
On the 23rd,	12.8	
On the 24th,	12.8	
On the 25th,	13.1	

Adjourned until 2.00 p. m.

10798 2.00 p. m., Wednesday, February 24, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH,

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. From your knowledge of the water course from Chicago to St. Louis and taking into consideration all stages of the river during all seasons of the year since 1900, together with the float experiment which you have introduced in evidence, and considering the volume of water discharged into the Illinois river by the drainage canal, and by the tributaries of the Illinois river what is your opinion as to the mean average time it takes water to flow from Lake street in the city of Chicago to the Eads bridge in the city of St. Louis by way of the Chicago river, the Drainage Canal, the Desplaines river, the Illinois river and the Mississippi river?

A. I think that the result of this experiment of floats 10799 comes about as near it on an average as anything that you will ever get.

Q. My question is, what is your opinion?

A. Well, I will substitute, that in my opinion this comes as near to the average as anything that you will ever get.

Q. Have you the annual reports of the Health Commissioner of the City of St. Louis for the years 1893 and 1894, 1895 and 1895-6, known as the 17th, 18th and 19th annual reports of the Health Commissioner, respectively?

A. I have.

Q. Will you turn to page 11 of the report as found in the 17th annual report of the health commissioner of St. Louis for the years 1893 and 1894 and read that part of the report that refers to Illinois river pollution?

MR. JEFFRIES: I object to the form of proof. I object to the reading of the pages in question in evidence for the reason that it constitutes no defense in this case and for that reason is incompetent, irrelevant and immaterial.

A. "ILLINOIS RIVER POLLUTION. The existing 10800 indisputable proof of the contamination of the Illinois river by constant discharge into its channel of a large quantity of sewage and the fact that it joins the Mississippi a number of miles above the site of the intake of the local waterworks suggested the reflection that with the completion of the gravity drainage canal now under construction from the Chicago river to the basin of the Illinois river the sanitary peril attending the unguarded use of the Mississippi water could not in justice be longer unnoticed or ignored. This consideration led to the recommendation that special inquiry be instituted in this regard and resulted in the chemical examination by the department of samples of water taken from the channel of that stream in October."

MR. JEFFRIES: I move to strike out all that part of the report of the City Board of Health of the City of St. Louis just read in evidence, for the reason that it is not binding upon complainant and can not be construed into an admission of any character so far as this complainant is concerned and for the further reason that the conditions now existing and which have
existed since the opening of the drainage canal did
10801 not exist at the time the report was issued or published,
nor at any time prior to the opening of the drainage canal
and for the further reason that such statements are incompetent, irrelevant and immaterial and for the further reason that there was no authority shown that said board had the power or that it is required of said board as one of its duties to embody such determinations or findings in their report.

MR. TODD: Will you turn to page 36 of the same report and read the resolution adopted by the regular meeting of the Board of Health of the City of St. Louis, August 31st, as it appears upon that page?

MR. JEFFRIES: I object to the question for the same reasons stated in the last preceding objection and motion to strike out.

A. "REGULAR MEETING, AUQUST 21st. The following was adopted: Whereas, the present pollution of the Illinois river from a point near Joliet to its mouth by the discharge into its channel of sewage from Chicago seems indisputable from the evidence at hand; and,

Whereas, preparations are now being made by means of
10802 the construction of the drainage canal to pour a still
larger volume of sewage from the same sources into said
river; and,

Whereas, the delivery of this impurity into the Mississippi river so near to St. Louis and the strong probability that the public water supply here will be injuriously affected thereby makes the subject one of interstate importance;

Therefore, be it resolved by the Board of Health of St. Louis, that his honor, the mayor, and the honorable municipal assembly be and are hereby respectfully requested to memorialize Congress concerning this mattter and request that a suitable commission be appointed without grievous delay with powers to fully investigate the subject of the extent of the present and prospective pollution by sewage from Chicago of the Illinois and Mississippi rivers in order that the probable amont of danger to the public health therefrom and all other pertinent facts in regard thereto may be made known."

MR. JEFFRIES: Now, I move to strike out the resolution as read for the same reasons as embodied in my objection
10803 to the question and for the same reasons embodied in my motion to strike out the last preceding question and answer.

MR. TODD: Will you turn to page 38 and read the resolution that was adopted or rather that was offered and referred at the regular meeting of September 28th, as it appears in the same report.

MR. JEFFRIES: I object to that for the same reason previously stated.

A. "REGULAR MEETING, SEPTEMBER 28th. The following resolution was offered and referred: Ordered by the Board that the city chemist be and is hereby directed to proceed to collect samples of water for chemical analysis and such other examination as may by the Board be deemed necessary from the channel of the Mississippi river at the chain of rocks, said samples to be taken in such number and at such times as may be determined by the health commissioner and the results of the analyses of same and such other material information as may be elicited be reported from time to time to this Board."

MR. TODD: Will you please read the proceedings of the Board at the regular meeting of October 16th as appears on page 38 of the same report?

10804 MR. JEFFRIES: I object to the question for the same reasons previously stated.

A. "Regular meeting, October 16th. The following communication from the city chemist was read: I have the honor to report that in compliance with the resolution adopted by the Honorable Board of Health on October 9th, I have collected 22 samples of water from the Mississippi and Illinois rivers on October 11th, 12th and 13th as follows:

October 11th, 9 samples while proceeding on the steamboat Cherokee from the Chain of Rocks to Grafton.

October 12th, 4 samples of Mississippi river water between Grafton and a point 5 miles north of the Illinois river.

October 12th, 4 samples of Illinois river water between Grafton and a point 3 miles north of the mouth of the Illinois river.

October 13th, 5 samples of Mississippi river water between Alton and the chain of rocks, while proceeding from Alton to St. Louis on the steamboat Cherokee.

In conformity with the resolution mentioned above I have begun with the chemical analysis of said samples this day and shall report the result as early as possible, giving the same precedence over all work previously ordered to be executed by the Honorable Board." 10805

MR. TODD: Will you please turn to page 42 of the same report and read the report made at the regular meeting under date of December 4th in said report?

MR. JEFFRIES: I object to the question for the reasons previously stated.

A. "The following report of the city chemist was read: By order of the Honorable Board and under direction of the Health Commissioner I collected 22 samples of water from the channel of the Mississippi river from the chain of rocks to a point 5 miles above the mouth of the Illinois river on October 11, 12th and 13th, and in compliance with my instructions requesting merely a chemical analysis of these samples of water I herewith present my report on the chemical examination of the same.

In conformity with the object of this analysis to ascertain the character of the sewage contamination supposed to exist in the Mississippi river I confined my tests to those usually employed by analysts for such purposes and I have the honor to report the following results on this basis of examination, as presented by the appended table. 10806

In summarizing briefly the facts presented in this report I respectfully call the attention of the honorable Board of Health to the following conspicuous features:

1st. The large amount of free and albuminoid ammonia found at various points of the Mississippi and Illinois river and indicating considerable contamination, largely in excess of the limits adopted by expert analysts and scientific bodies.

2nd. Nitrates and nitrites were identified in all the samples of water, but neither of them exceeding the limits usually considered allowable.

3rd. Organic matter was found in very large proportions, signifying pollution to a certain degree, although a liberal allowance should be made for the presence of organic substances not strictly considered as impurities in river water.

4th. A remarkable fact is the large amount of chlorides present in the Illinois river, being twice as much as good drink-
ing water should contain, unless originating from a
10807 saline subsoil.

In order to ascertain whether or not such sewage pollution takes place in the Illinois and Mississippi rivers, I would suggest that the Health Commissioner be authorized by the Honorable Board to have additional samples collected and analyzed.

MR. TODD: Will you turn to page 43 and read the proceedings at the regular meeting of December 21st in the same report?

MR. JEFFRIES: I object to the question for the reasons previously stated.

A. Regular meeting, December 21st. The Board adopted the following report of committee, to whom was referred the Health Commissioner's communication submitted on the 11th inst.: In their judgment the further examination of the water supplied to this city in the manner and by the methods indicated is quite as important as stated by the Health Commissioner. And such an examination will be absolutely necessary if either of the measures suggested for the protection of the
water supply is to be adopted or advocated.
10808 At the same time it is submitted that such an examina-
tion will not only involve quite a draft upon the resources of the department, but must also for some time engage the attention of the city chemist and his force to the exclusion of all other work mapped out for him.

It is suggested, therefore, by your committee that before finally ordering the city chemist to proceed with the work proposed it may be well to ascertain the attitude or opinion of those city authorities upon whom it will be incumbent to move for the protection of our water supply, either by legal proceeding, petition to Congress or otherwise. The whole matter was then referred to the mayor."

MR. TODD: Will you proceed and read the letter from the mayor of January 6th, on page 45 of the Health Commissioner's Report of the City of St. Louis, in the same report?

MR. JEFFRIES: I object to the question for the reasons previously stated.

A. Regular meeting, January 8th. The following correspondence between the Mayor and Health Commissioner was submitted to the Board. Letter from the Mayor, January 6th:

I have received yours of the 22nd with accompanying reports bearing on the subject of the quality of the water of
10809 the Mississippi river between the chain of rocks and a point 5 miles above the mouth of the Illinois river as recently determined by the city chemist. Also charts illustrating the results arrived at by a chemical examination.

I have examined these charts and reports as carefully as my want of technical knowledge will permit. The result of the work is undoubtedly presented in a very graphic manner; indeed, it seems to me that a technical knowledge is hardly necessary to understand the results as shown by the reports and charts before me, assuming that the work of the city chemist so far as it went was thorough and reliable. I have no reason to doubt that the city chemist, Teichmann's, work can be depended on as representing the true conditions. It is my understanding that this investigation was the result of a suspicion that our water supply was being contaminated by Chicago sewage coming from the Illinois river.

Briefly, then, I find from the charts before me conditions as follows:

Substances supposed to contaminate drinking water in dangerous quantity in the Illinois river, also spots in the Mississippi river between the mouth of the Illinois and the chain of rocks and in the mouth of the Missouri river. I find, however,
10810 that at Grafton, about 1 mile and a half below the mouth of the Illinois the water is purer than at any other point in the river between Grafton and the chain of rocks. That is to say, nothing of the objectionable substances seem to exist in dangerous quantities one mile and a half below the supposed source of contamination, while the pollution increases and diminishes below that point at irregular intervals. This, it seems to me, tends to disprove the theory that the contamination (if there be any) at the chain of rocks comes from the Illinois river and

goes to show that the offensive substances found in spots along the river between the mouth of the Illinois and chain of rocks are due to local causes. The comparative purity of the water at Grafton seems to be inconsistent with the theory that the water below that point is contaminated from the water from the Illinois river. The conditions existing at the mouth of the Missouri river, as shown by the chart, suggest that as a much more probable source of the pollution than the Illinois river.

In view of these conclusions which seem to me necessary upon the facts before me I do not think further superficial investigations would be desirable at this time. In fact, it seems to me the tendency of the work done by our
10811 City Chemist is to give confidence in the purity of the water supply at the chain of rocks so far as influences are concerned within our control affecting the water at that point and I am, therefore, inclined to think that if further work be done the investigation should be conducted by a commission of thoroughly equipped experts, backed by sufficient appropriation of money to enable them to make an exhaustive and final report. The money at command under your present appropriation seems to me, not sufficient to do more than has already been done by Dr. Teichmann with seeming thoroughness. If sufficient funds can be made available to prosecute further work with thoroughness I shall be glad to co-operate with you to a final settlement of this vexed question."

MR. TODD: Will you turn to page 64 of the same report and read that part of Dr. Teichmann's report to the Board regarding the analysis of the Mississippi river water as appearing in the same report on that page.

MR. JEFFRIES: I object to the question for the reason previously stated.

A. "3rd. Regarding the analyses of the Mississippi, Missouri and Illinois river water, by my elaborate report of December 4, 1893, I most earnestly recommended the con-
10812 tinuation of these examinations. Owing to my orders from the Honorable Board, I could only take samples from the mouth of the Illinois river. It was therefore impossible for me to determine the source of contamination found at that point unless additional samples of water along the Illinois river could be analyzed and local conditions inspected personally.

The original purpose of these investigations being to ascertain the extent of present and future sewage pollution of our water supply from the Illinois River, and indirectly from the Chicago drainage canal. I consider the speedy continuation of these investigations a matter of grave importance to our community. A system of thorough chemical and bacteriological examinations conducted at short intervals during a period of two years would contribute much towards the settlement of this great sanitary problem and would very likely encourage national legislation for the purpose of preventing municipal communities from emptying their sewage into potable rivers."

Mr. Todd: Will you turn to the 18th annual report of the Health Commissioner for the year ending March 31, 1895,
10813 and read on page 11 that part of the report under the heading "Federal Rivers Commission."

A. "FEDERAL RIVERS COMMISSION. A movement on the lines suggest in the report for last year was made in January by Hon. Richard Bartholdt, through the introduction into Congress of a bill which reads as follows:

A Bill to appoint a commission for the investigation of the pollution of water supplies where such pollution affects or threatens to affect the sanitary condition of the people of more than one state.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That a Commission shall be appointed to investigate fully the subject of the pollution of rivers and other sources of water supply where the sanitary condition of the people of more than one state is affected or threatened to be affected by such pollution, this commission to consist of three members, to be appointed by the President, by and with the advice and consent of the Senate, whose compensation during the time when
10814 actually engaged in the performance of their duties under this act shall be Ten Dollars per diem each and reasonable expenses.

Sec. 2. That the Commission shall meet in Washington, District of Columbia, within thirty days after the passage of this act to consider the methods to be adopted in the investigation, and it shall have authority to be empowered to make use of the services of chemical, bacteriological and sanitary experts, and such persons as it may judge most competent by reason of their special knowledge and experience to afford it correct information on the subject of its inquiry, as well as in formulating its methods as in carrying them into effect. It shall meet thereafter from time to time at such places as it may consider best suited for the furtherance of this inquiry.

"Sec. 3. That the commission shall report to Congress at its next session the progress made in the investigation undertaken under this act and shall submit such suggestions as may seem desirable, with the view of remedying any unsanitary conditions that have been developed by its work.

Sec. 4. That the sum of .... thousand dollars, or so much thereof as may be necessary, is hereby appropriated, to pay the salaries and expenses of said commission and
10815 carry out the purposes of this act."

The General Assembly at its late session adopted a joint resolution asking the Missouri Congressmen to support this measure and it is to be regretted that its introduction was delayed so long—the bill having died with the session—as, to judge by the expression of the sanitary opinion from the principal parts of the country, the time was ripe for legislation of this kind. Certainly no more important field is offered to progressive science and the thorough investigation as proposed of all streams touching more than one state would yield the data of the very highest practicable value to all concerned in the protection and preservation of the public health.

The defilement of natural water courses has become one of the most conspicuous evils of modern civilization and the harm and wrong are of such magnitude in this country that only the powers of the general government are adequate to deal with them properly. States and municipalities situated near the head waters of potable streams are not so seriously threatened in this respect, but the great bulk of urban population is found on the middle and lower reaches of such water course, hence the necessity for vigilant precaution.

10816 The invasion of this valley by a flood of filth naturally foreign to it, as is proposed by the construction and operation of the sewage canal leading from Chicago to a tributary of the Illinois River, will tend to enormously increase existing danger due to pollution of the upper Mississippi and from other sources and of the Missouri river from the sewage outflow of Kansas City, Leavenworth, St. Joseph, Omaha, etc.

"St. Louis is the focal point of all this drainage and must bear the brunt of the attack as best she may. No place of any considerable size below, drawing public supplies from the channel of the Mississippi River, therefore the means of prevention and correction should be most diligently considered here now."

At page 11 an asterisk at the bottom of the page is in words as follows: "This measure was drafted in December, 1894, by Major Charles Smart, Surgeon United States Army upon the request of the Health Commissioner, later submitted to his Honor, the Mayor and by him forwarded to Washington."

On page 12 a foot note is indicated by an asterisk immediately after the word resolution as heretofore quoted, and it is as follows: "Be it resolved by the General Assembly of the State of Missouri as follows: That our senators and representatives in Congress are requested to vote and urge the 10817 passage of the bill authorizing the National Commission to investigate the pollution of streams, the waters of which flow through or adjacent to more than one state." Approved March 9, 1893.

Mr. Todd: Will you turn to page 25 of said 18th annual report and read what is there stated about a local commission?

Mr. Jeffries: I object to the question for the reason previously stated.

A. "That a local commission be formed under municipal authority to inquire fully into the quality of the water supply of St. Louis."

Mr. Todd: Will you turn to page 43 of the 19th annual report of the Commissioner of Health of the City of St. Louis for 1895-6 and read what is stated there under water supply?

Mr. Jeffries: I object to the question for the reasons heretofore stated.

A. "Water Supply. The question as to the influence of the Chicago Drainage Canal as now in course of construction upon the water supply of St. Louis is one that should not be lost sight of. A bill creating a Federal Commission to investigate and suggest congressional action of a remedial character is now before Congress. It is hoped that such a law be 10818 enacted that selections for membership of the Commission may be made that will recognize and protect the equitable demands of each locality."

Mr. Jeffries: I move to strike out all that has been read of the reports of the Health Department of the city of St. Louis by this witness for the reason that the same is incompetent, irrelevant and immaterial and for the further reason that the conditions complained of are such as existed or may have existed subsequent to the opening of the drainage canal and not such as existed prior thereto and for the further reason that by the opening of the drainage canal conditions were brought about in the Illinois and Mississippi Rivers entirely different from what existed prior thereto, and for the further reason that the defendants' own testimony shows that the longevity of a disease producing germ to be less in highly concentrated sewage polluted waters than in less concentrated or a more highly dilute condition.

Mr. Todd: Who was the sewer Commissioner of the city of St. Louis from 1887 to 1891?

A. The published list of officers shows that Robert E. McMath was Commissioner of sewers.

10819 Q. During the time that he was connected with the municipality of St. Louis do you know of any report made by him upon the question of the Illinois River?

A. I know that he delivered an address of May 30, 1888, before the Engineer's Club of the City of St. Louis and that address appears in the Journal of the Association of Engineering Society beginning on page 316, for the year 1898.

Mr. Jeffries: I object to the question and move to strike out the answer because it is incompetent, irrelevant and immaterial.

Q. Is the paper in which that address was delivered a paper of general circulation?

Mr. Jeffries: I object to the question for the reason that it is an endeavor to introduce statements made by Mr. MacMath without putting him upon the witness stand so that the complainant might have an opportunity to cross examine him.

A. The paper was very generally circulated amongst engineers of the United States.

Mr. Todd: Will you read that part of the address de-
10820 livered by Mr. McMath, the Sewer Commissioner of the
city of St. Louis in the city of St. Louis and published
as you have indicated, in 1888?

MR. JEFFRIES: I object to the question for the reason that Mr. McMath is still living and no effort has been made upon the part of the defendant to place him upon the witness stand in order that the complainant might have an opportunity of cross examining him and for the further reason that whatever might have been said at the time, applied to conditions that existed prior to the opening of the drainage canal and not subsequent thereto, and for the further reason that whatever he might have said would not have been binding upon the complainant, and does not constitute in any way a justification of the defendant in committing the nuisance complained of.

A. The volume containing this publication is in the library of the Western Society of Engineers. I have simply made from it such notations as I thought were necessary.

MR. JEFFRIES: I object to the witness reading into the
record only such parts of the address referred to as he
10821 desires, unless he reads the whole address, and all that
was said upon the subject at the time by the party in
question.

MR. TODD: In reply will state that if the complainant desires the whole document the same will be produced and read in evidence on request made on cross-examination.

MR. JEFFRIES: I would like to have the article present so that I may examine it.

THE WITNESS: He starts out by describing the project—

MR. JEFFRIES: I object to the witness relating in a second hand way what the article contains, for the reason that it is incompetent, improper, immaterial and irrelevant and for the further reason that it is not responsive to the question.

(Question repeated.)

A. I can only read such parts as I made notations of in the book which I hold in my hand: "The project contemplates first a canal from Lake Michigan to the Des Plaines river, Joliet being the objective point, having a capacity to carry the volume of at least 10,000 cubic feet per second, at a velocity consistent

with the use of the canal for navigation. Said Canal to be
10822 the outlet for Chicago drainage. The volume being made
ample to carry sewage without objectionable pollution."

Then follows a discussion of the effect upon Lake Michigan, which I simply put in for my own information, and it does not bear upon this case at all. I skip to where it strikes this question:

"Of the flood discharge of the Illinois River, we have no direct measure. Taking the differences between the gauges of the Mississippi at Hannibal and at Grafton for 1881, maximum difference of 79,000 cubic feet per second appears to be the maximum discharge of the Illinois River. At the lowest stage, the lowest discharge at the mouth of the Illinois River was by measurement in 1866 about 1200 cubic feet, which has now increased to about 2000 cubic feet, by water pumped at Bridgeport."

Skipping to page 319 of the address:

"The normal fall from La Salle to the mouth of the river is equal to .13 per mile, the distance is 225 miles.

On page 320 he begins:

"The treatment of the Sanitary effects, and on page 322,
he states Disinfection may become necessary for all cities.
10823 This is no more applicable to Chicago than to St. Louis."

On page 322: "In 1879, water passing through the Illinois and Michigan canal was 9,000 cubic feet per minute. At Joliet, 33 miles below Bridgeport, the water falling over the dam, gave off odors comparable to those arising when a privy vault was being emptied. Increased volume from pumping works, about 45,000 cubic feet per minute. Sewage in 1886 could not be traced farther than Ottawa."

On page 324 he states: "That the general result is a betterment."

This paper was discussed by Messrs. Seddon, Prof. J. B. Johnson, Messrs. Wheeler, Boughton, and Holdon.

MR. JEFFRIES: I move to strike out the witness's answer to the preceding question in which he undertook to read into the evidence statements made by Mr. McMath in an address delivered by him in 1888 for the same reasons stated in my objections to the question, and for the further reason that the answer is in no way responsive to the question, and for the

further reason that the witness has interjected his own opinion
as to what McMath meant by the use of certain words, when
such evidence, if admissible under any circumstances
10824 whatever, should be admitted as a whole, in order that
the Court might determine the purport, meaning and
spirit of the language used.

10825 Q. Will you turn to page 12 of the Seventeenth Annual
Report of the Health Commissioner of St. Louis, for
1893-4, and read what is said under wells?

Mr. Jeffries: The same objection is interposed here on the part of the complainant to this evidence, and for the same reasons as stated in the objections interposed to previous readings from said reports.

A. "WELLS. The examination by chemical tests of water taken from surface wells in different parts of this city progressed memorably during the year, and a number of these sources of contaminated water supply for households have been condemned. The standard of allowable impurity established for the purpose of this undertaking is quite liberal, but even as thus measured, very many wells were found to contain water utterly unfit for human consumption."

Q. Will you turn to page 63 and read from the annual statement as found in the Seventeenth Annual Report of the Health Commissioner of St. Louis for 1893-4, what is said there about wells?

Mr. Jeffries: Same objection.

10826 A. "Number of samples of well water analyzed 2. Pri-
vate wells, 239; b. public wells, 8. Number of impure
wells reported for condemnation: a. private wells 41. b. pub-
lic wells 5."

Q. Will you turn to the bottom of the same page and read what is said in regard to the analysis of wells, etc.

Mr. Jeffries: Same objection.

A. "Reviewing this work I respectfully venture the following remarks and suggestions:

1. The analyses of well and cistern water were based strictly upon the standard adopted in the month of September, 1893, by the Commission appointed by the Honorable Board, and consisting of Professor Charles O. Curtman, Chairman, Professor Charles R. Sanger, Professor William B. Potter, Dr. Otto

E. Forster, Hon. David W. Caruth, Chief Sanitary Officer, Charles W. Francis, and the undersigned. According to this standard all wells and cisterns are to be condemned as impure and unwholesome which contain: 1. More than 0.05 parts of nitrogen in the form of nitrites, per million parts of water; or second, more than 0.01 parts of nitrogen in the form of nitrites per million parts of water, in conjunction with 0.15 parts nitrogen in the form of free ammonia per million parts

10827 of water and 100 parts of chlorine per million parts of water, or 3rd, nitrogen in the form of albuminoid ammonia to the extent of 0.2 parts per million parts of water, or 4th, phosphoric acid or phosphates as ascertained by the characteristic turbidity produced upon the addition of ammonia molybdate. Although the analyses of wells thus far made do not represent every ward in the city, the comparatively large number of wells found to be impure, averaging about 1 out of 5, fully justify the vigorous continuation of these examinations. The Sanitary Division has already presented a list of nearly 3,000 wells and with proper facilities provided by appropriations I expect to be able to analyze the larger part of this number during the present fiscal year in addition to the other expected work. The principal object of these examinations of wells being sanitary, bacteriological investigations should be included wherever the indications call for them. The last annual appropriation did not provide for the purpose of bacteriological apparatus, therefore such examinations could not be made."

Q. Will you turn to page 215 of the health reports of the

10828 18th Annual Report of the Health Commissioner for May 31st, 1895, and read under the head wells contaminated, total number of wells.

Mr. Jeffries: Objected to for the reason it is incompetent irrelevant and immaterial and has no bearing upon the issues involved in this case, inasmuch as it relates to conditions prior to and not subsequent to the opening of the drainage canal.

A. "Total 59 wells."

Q. Will you turn to page 65 of the same report and read what is there under wells?

A. "Wells. 59 wells have been condemned by the Board of Health and very few have been closed. The standard which was established by the Board of Health in relation to wells should be legalized by the Municipal Assembly. Where City water is on any premises and where it is desired to retain the well for stock or washing purposes, a permit to do so should only be given under certain binding conditions—the Assembly should enact the law."

Q. Will you turn to page 204 of the same report and read the table showing the total number of wells by wards in the city of St. Louis, April 1, 1895?

Mr. Jeffries: Objected to as immaterial.

10829

	Ward	Public Wells on Street.	Total Number of Wells in Ward.
	1	6	19
	2	2	20
	3	2	57
	4	10	148
	5	23	291

	24	13	46
	25	6	116
	26	57	210
	27	30	284
	28	4	79
		— —	— —
	Total	437	4848

Q. Will you turn to page 66 of the 19th Annual Report of the Health Commissioner for 1895 and 1896 and 1897, that part of the report of the meeting of August 1, 1895?

Mr. Jeffries: Objected to for the reason it is immaterial and not competent evidence.

A. A communication was submitted by the Health Commissioner in reference to the report of the City Chemist on analyses of the water from seven wells, the water of which is impure according to the standard adoption by the Board of Health some two years ago. The communication was made the basis of the following resolution, which on motion duly seconded was adopted:

"Resolved that hereafter the City Chemist shall make no examinations of well or cistern water unless by special direction of the Health Commissioner."

10831 Mr. Jeffries: I move to strike out all the testimony of this witness wherein he has read into the record excerpts of the reports of the Board of Health of the City of St. Louis, for the reason that the same are immeterial and do not constitute competent evidence.

CROSS EXAMINATION

By Mr. Jeffries.

Q. Mr. Randolph, was there any record kept of the times and periods the water in the Chicago River flowed into Lake Michigan prior to the opening of the canal?

A. No sir, we have no such record.

Q. Is it not a fact that there were periods of several weeks and months in which the water did not pass from the river into the lake but remained as a stagnant pool in the Chicago River?

A. There was no extended period in which there was not some current either to or from the lake.

Q. Can you give any approximation of the time ?

10832 A. No sir, I can not.

Q. Is it not a fact that since the opening of the canal the water from the various cribs in Lake Michigan from which the water supply of Chicago is drawn, is condemned by the Health Department.

A. It is frequently pronounced unsafe by the Health Department.

Q. And citizens using it for domestic purposes are requested to boil that water?

A. That is true.

Q. And such conditions obtain and have obtained regardless of whether there was a freshet which carried the water of the Chicago River back into the lake is it not?

A. That is true.

Q. Do you know whether or not there was any record kept of the number of freshets and the time of their happening prior to the opening of the drainage canal which carried the water from the river into the lake?

A. I have no knowledge of any such record.

Q. You do not know whether they were kept or not?

A. No sir. If they were kept it was by the city of Chicago.

Q. The sanitary district did not keep that?

A. They did not keep that.

Q. Does the sanitary district keep such record since the opening of the canal?

10833 A. No sir. It is a condition which we do not intend should obtain at any time, and all that we do is to keep track of the floods in the north branch and keep the flow from our channel so as to care for those floods.

Q. In fact it is a condition which has rarely happened since the opening of the canal?

A. So far as I have any information or knowledge there is only one occasion when it was notably true.

Q. And that was upon the occassion of the Joliet flood?

A. No sir. I got no complaint of it at that time, strange to say, but it was at a time when there was a flood in the north branch, which was not watched by our people.

Q. And the dam was not lowered to a sufficient depth to permit the necessary flow?

A. To carry it off, yes sir.

Q. At the time of the Joliet flood there was no local freshet at Chicago but the dam was set to a certain height to stop the running of the water through the canal and to carry it to a lake level in order to protect the people below that point, from the local freshet there?

10834 A. Yes sir, that was done.

Q. How long has it been since the 12th Street and the 22nd Street sewers were diverted from Lake Michigan?

A. I have not those exact dates but the best of my recollection is about two and one-half years ago.

Q. They have been diverted from the lake since the opening of the sanitary canal?

A. Yes sir.

Q. And they discharge now into the Chicago River?

A. Yes sir.

Q. And thence into the canal?

A. Yes sir.

Q. What other sewers that you know of besides the 12th and 22nd Streets sewers which formerly discharged into the Lake Michigan have been diverted through some other source?

A. Those are the only two sewers whose diversion I have any knowledge of.

Q. State if you know the extent of population of the territory sewered by the 12th Street and the 22nd Street sewers?

A. I can not give it. I can not differentiate between those sewers and sewers leading from the same general territory which discharged previously into the Chicago River. 10835

Q. Can you give the size of those sewers at the point of discharge?

A. I can not give the 12th Street. The 22nd Street, as I remember it, is a 12 foot sewer.

Q. Those two sewers, to-wit: the 12th Street and the 22nd Street sewers receive the sewage from populous communities do they not?

A. Yes sir, very populous.

Q. How does the population of the territory sewered by these two sewers compare with the population generally throughout the city, in point of numbers?

A. My judgment is that excepting the densely populated business district included within the loop it is the maximum population of anything outside of that area.

Q. How does the population or the territory sewered by the 12th and 22nd street sewers compare with the population sewered by such sewers as have discharged directly into the Chicago

river at and as did directly discharge into the Chicago
10836 river prior to the opening of the drainage canal and
prior to the diversion of the 12th and 22nd Street sewers
from Lake Michigan to Chicago river?

A. There is territory on the north side extending as far north as Chicago avenue, and on the west side parallelling the river, as far west as Halsted street that is of about the same density as the population sewering into the territory about which you have just asked. Those three sections are about on a par as far as population is concerned. Outside of that area the population is less dense. I think that the population draining in the 22nd and 12th Street sewers is about the same density as that draining directly into other sewers which pass into the river between Van Buren street and 22nd street. You see, there are other sewers besides these that also empty into the river, taking sewage from that same territory.

Q. Then it is your judgment that about the same number of people reside in the territory sewered by sewers discharging directly into the Chicago river as are sewered by the 12th and 22nd Street sewers, confining yourself to the immediate territory in which the 12th and 22nd Street sewers are located?

A. That is the ratio of population to area is about the
same for the territory discharging into the 12th and
10837 22nd Street sewers as for the territory discharging
directly into other sewers which pass into the river
between Van Buren street and 22nd street.

Q. In your opinion are there as many people sewered by the 12th and 22nd Street sewers as are sewered by the sewers in that immediate locality, discharging directly into the Chicago river?

A. No, sir; I do not think there are as many.

Q. Now, in these last answers, what is the extent of the smaller sewers that you have taken into consideration with reference to the location of the 12th and 22nd street sewers?

A. There are sewers coming in at Harrison street, at Polk street, at Taylor street, all of them north of Twelfth street, and there is nothing from Taylor street until you come to Twelfth.

Q. Can you give the approximate boundary of the territory sewered by the 12th and 22nd Street sewers?

A. No, sir, I can not. There are small sewers coming into them that I have not in mind.

Q. Can you state approximately the population of the City of Chicago in the immediate vicinity of the 12th and 22nd Street sewers, taking into consideration the population in the
10838 territory sewered by the small sewers in connection with the 12th and 22nd street?

Adjourned until 10:00 a. m., February 25, 1904.

10:00 A. M., Thursday, February 25, 1904.

10839 Continuation purusuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ISHAM RANDOLPH

resumed the stand for further cross examination by Mr. Jeffries, and testified as follows:

A. The population tributary to the 12th and 22nd Streets sewers I estimate to be from the First Ward 8225, or one-third of the resident ward population; from the second ward 25,692, or 90 per cent of the resident population of the ward. Total, about 34,000. An exact determination can only be had by making a house to house canvass. This answer is based upon the resident population shown by U. S. census and excludes the non-resident business population. In these wards a large area is devoted to railroad yards.

Q. Outside of the territory between the Chicago River and the territory formerly drained by the 12th Street Sewer, the territory of the city of Chicago now drained by the 12th and 22nd street sewers direct into the south branch of the Chicago River and which formerly discharged into Lake Michigan
10840 is about as populous as any part of the city of Chicago?

A. It is as populous as any part of the city of Chicago.

Q. Is there any sewage south of the Chicago river drained directly into the lake today?

A. Yes sir; the 35th Street sewer is draining into Lake Michigan.

Q. Can you give approximately the population of the district sewered by the 35th street sewer?

A. The population tributary to the 35th Street sewer is about 22,000, or 66 per cent. of the resident population of the Third Ward.

Q. Is that the only sewer that drains now directly into Lake Michigan, south of the Chicago River?

A. No sir. The 41st street drains directly into the lake.

10841 Q. What others?

A. The sewer on 43rd street drains directly into the lake. The sewer on 45th street drains directly into the lake. The sewer on 51st street drains into the lake. The sewer on 56th street drains into the lake. The sewer on 71st street did drain into the lake until a short while ago. Whether it does now I can not say. The last time I passed in sight of that pumping station it was apparently abandoned, as the windows were boarded up.

Q. If the sewage from that sewer does not now discharge into the lake where could it discharge?

A. There is a 2 foot sewer passing directly into the lake parallelling the 6 foot sewer which lead from the pumping station, and apparently the only outlet from this sewer would be through this two and one-half foot sewer.

Q. What other sewers south of the Chicago River drain directly into the lake?

A. There is a sewer on 83rd street draining to the pumping station at Mackinaw Avenue, and the sewage is pumped into the lake from that point. That is the most southerly sewer draining directly into the lake.

Q. Will you give the population of the drainage drained
10842 by these respective sewers which you have just named as
discharging their sewage into Lake Michigan?

A. The population sewering into the Lake south of the area tributary to the 35th Street sewer is, approximately, as follows: 6th Ward, 60,216; 7th Ward, 36,844; 8th Ward, 10,000; 33rd Ward, 31,135. Total, 148,195.

Q. Is any arrangement or plan being made by which the sewage from the territory now drained by these sewers into Lake Michigan will be diverted from the lake?

A. An intercepting sewer is nearly completed, extending from 73rd street north to 39th street which will take all of the sewers which have heretofore emptied into the lake between 73rd and 39th. At 39th the accumulated sewage from the intercepting sewer will be pumped into 39th street conduit and flow, west into the south branch of the Chicago River.

10843 Q. How near is that intercepting sewer completed?

A. It will probably be completed within six months from now.

Q. Now, after it is completed, all the sewage of the city of Chicago lying south and east of the Chicago River and the south branch of the Chicago River will be drained directly into either the Chicago River or the canal?

A. Yes sir.

Q. Now, then, Mr. Randolph, will you state whether or not there are sewers north of the Chicago River which discharge directy into Lake Michigan?

A. There are.

Q. Will you please state where those sewers are located?

A. Those sewers begin on the north at the first street north of Diversey Avenue. The next sewer is Belmont Avenue. The next one is on Nevada Street. There is a short one on Addision Street; one on Wavon Avenue; one on Grace Street; one on Irving Boulevard; one on Wilson Avenue; one on 59th Street, North; one on Brin War Avenue; one on the first street south of Greenlake Avenue; one on Grand Avenue.

Q. Now, can you give the population sewered by the sewers that you have just mentioned? I mean the population
10844 of the territory sewered by the sewers you have just mentioned?

A. These sewers are all in the 25th Ward and accommodate about 90 per cent of its population, approximately 49,000.

The answers which I have given are based upon an examination of the ward maps, sewer map and U. S. Census of 1900 covering each ward. An absolute determination can only be made by a house to house canvass to determine the number of people draining into any particular sewer.

Q. All of the sewers north and east of the Chicago River discharge directly into the main river or the north branch?

A. Yes sir. The city is constructing an intercepting sewer from the lake front, extending from Melrose Street on the south to the city limits on the north.

Q. And when that intercepting sewer has been completed it will divert all of the sewage in that part of the city of Chicago lying north of the Chicago River and east of the north branch of the river from Lake Michigan into either the main
10845 river or the north branch?

A. With the exception of two small sewers on Surf Street and on Belmont Avenue.

Q. Is any arrangement being made to divert the sewage from those two streets?

A. Not that I am advised of.

Q. State whether or not it is the intention of the sanitary district to divert all of the sewage that is now being discharged into Lake Michigan from the lake into the river or the drainage canal?

A. The Sanitary District of Chicago has never assumed any jurisdiction over the sewers of the city. They are entirely in the hands of the city authorities. The city has made the arrangements for the intercepting sewers and plans for diverting sewage from the lake into the intercepting sewers. The sanitary district is to operate the pumps or pumping works for ever, which disposes of the sewage which is brought to the pumping works and discharges it in channels provided by the Sanitary District.

Q. So the two corporations together are working to that end?

A. Yes sir.

10846 Q. In giving the amounts of sewage discharges into the river at the present time, and during the past three years as shown in your direct testimony, did you take into consideration the amount of sewage that was discharged into Lake Michigan by means of the sewers which discharged directly into that lake?

A. I do not.

Q. All of the water as used by the people of the city of Chicago, as shown by the records of the water department was used by you in estimating the amount of sewage discharged into and through the drainage canal?

A. No sir, it was not. The per capita of water pumped was used, and the number of inhabitants draining either directly or indirectly into the sanitary canal was multiplied by that per capita to get at the sewage.

Q. Did you use the customary rate of 60 gallons per capita or that which actually existed in the city of Chicago?

A. I presented two tables. In one of these tables the actual pumpage is used and the results based upon that determination are given.

Q. Upon one of these tables you used 60 gallons as the basis and upon the other table what was the number of
10847 gallons used?

A. Upon the other table I used for each year the average consumption per capita for that year, ranging from 190 up to 197 gallons.

Q. What arrangements are now being made to take in the sewage discharges of the Calumet District and the district in north Chicago recently added to or annexed to the Sanitary District of Chicago?

A. Surveys have been made and plans have been perfected under which the sewage of the annexed district will be cared for. On the north it is proposed to build a canal from a point on the north boundary line of Evanston through to a junction with the north branch of the Chicago River at Lawrence Avenue. It is proposed to establish pumping works at the Evanston end of this canal and pump water in the canal sufficient to insure a constant flow.

The authorities of the territory thus drained have in contemplation the reversal of all sewers which now empty into the lake.

10848 Q. And that condition applies not only to Evanston on the north but also to Calumet on the south?

A. The theory is entirely different, but the object is the same.

Q. At the present time the sewage from the Calumet District is drained directly into the lake or into the Calumet River and from thence into the lake?

A. Yes sir, that is true.

Q. The object now is to reverse the channel?

A. To reverse the flow in the same manner as that done in the Chicago River.

Q. Mr. Randolph, state whether or not in your opinion the floats used by you in making your water velocity examination were in any way retarded by the character of the instrument used?

A. No sir, I do not think they were retarded.

Q. What effect had the velocity of the under current over the result of the ascertainment of the surface current as shown by the flow?

A. The floats as constructed were described in my previous testimony, and the hollow cylinder suspended from the surface float was constructed with a view to counteracting wind
10849 effects so that that hollow cylinder would always be feeling the effect of the current to such an extent which the float itself might not feel, if it was opposing the wind. The wind might over come it and I think that the mean result was about what we would have had on the float passing through a still atmosphere. I know it is impossible to get an ideal condition which will give perfect results.

Q. Then why do you take .8 of the actual surface flow in order to get the mean or true velocity?

A. This is unanimously advised by men who have made a business of testing the current of streams. I myself have never made a business of this. It has been an occasional thing with me and from my own actual obervations followed up by enough experiments which convince me in my own mind that it is true, I therefore take what is considered proper practice by men who have made this their business.

Q. Whatever effect the wind might have had upon the surface of the floats themselves would, to a certain degree, be exerted upon the cylinders passing down underneath the surface?

A. Only as transmitted by the string attaching the floats
10850 to the cylinder.

Q. Do you know the directions of the wind during this experiment?

A. I do not.

Q. Do you know whether there was a high wind or a low wind or any wind at all?

A. The wind is noted in the book, but I did not fix it in my mind when I read the report.

Q. I wish you would read from the book what notations were made with reference to the wind, during this experiment?

A. On July 15th a light northeast wind.

5 p. m. of the same day a northeast wind.

On July 17th the floats were not continued during the afternoon on account of severe wind storm.

Q. At what place on the river were these notations made?

A. Right at the Bear Trap Dam on July 15th, and in passing the lower end of Treat's Island at five o'clock that afternoon.

Q. The same afternoon?

A. Yes sir.

Q. Those are the only two places?

A. And when it was discontinued on the afternoon on July 17th on account of the severe wind storm.

Q. Now, when was that? Where was that?

10851 A. That was at Peru Highway Bridge.

Q. And from there on no notations were made?

A. No notations of the wind at all.

Q. Either as to its velocity or its direction?

A. No sir.

Q. Mr. Randolph, how wide approximately and how thick were these floats, or how deep?

A. I think they were about eight inches in diameter and about 2½ inches deep, but we have an exact sketch of them which I can put in.

Q. How far under the surface was this cylinder suspended on the float?

A. I can not answer that question. I was not with the party at any time and I could not say how deep they suspended it.

Q. Was that your instructions to the men who performed the experiment?

A. No sir, I left them uninstructed.

Q. They were to use their own judgment then?

A. Yes sir.

Q. What portion of the river has the most rapid velocity, 10852 with reference to its surface and under currents?

A. In a stream of uniform cross-sections it would be practically the center of such cross-sections, but the streams that I have observed of irregular cross-sections and irregular course you can not lay down any fixed rule as to where the highest velocity would be. I have seen it at times very close in shore and at other times out some distance in the stream. The highest velocity will approach the concave shore in rounding a curve.

Q. But in depth what is the greatest velocity?

A. The greatest velocity is at the surface.

Q. And this calculation of the mean velocity, by taking .8 of the surface velocity, is based upon experiments where only the surface velocity is taken?

A. No, sir, it is not based upon that. It is based upon experiments made partly with floats and partly with current meters, current meters submerged at different depths which will give different resulting velocities.

Q. Without knowing the depth in the water that these cylinders were suspended, how would you know to apply this .8 rule, and what would be the significance in applying it to the observations as found?

10853 A. Why, of course the depth of submergence would bear upon this question of applying the rule. The tables presented by me yesterday were, as stated at the time, prepared by my assistant, Mr. Crane, for me. Mr. Crane paid a great deal of attention to this work during its progress and he visited the work in progress, and had a more intimate knowledge of what went on than I had, as I never went on the work during the time it was in progress.

Q. Did Mr. Crane have it in charge?

A. Yes sir. Mr. Heilborn was the man who was constantly there. Mr. Crane was the man whom I held responsible.

ISHAM RANDOLPH.

10854 LUDWIG HEKTOEN

a witness called on behalf of defendants, being duly sworn, testifies as follows:

Direct Examination

By Mr. Todd:

Q. What is your name?

A. Ludwig Hektoen.

Q. What is your business?

A. Physician and Surgeon.

Q. From what institution are you a graduate?

A. I am a graduate of the College of Physicians and Surgeons, in Chicago.

Q. When did you graduate from that institution?

A. In 1887.

Q. After graduating what did you do?

A. I served as interne in the Cook County Hospital.

Q. For how long?

A. For 18 months. And I served as physician to the Coroner's office of Cook County for three years.

Q. During the time that you served as physician to the Coroner what were your duties?

10855 A. I would make post mortem examinations as required by the Coroner.

Q. How many post mortem examinations did you make during your term as Coroner?

A. I made several hundred, the exact number I do not know.

Q. What were your duties as interne at the Cook County Hospital?

A. Care of the patients in the hospital, passing from one form of service to another at regular intervals.

Q. What wards were you connected with?

A. At that time the services in the hospital were so divided that the interne served for a certain period in all the different wards.

Q. After you ceased your connection with the Coroner's officer, as Coroner's Physician, what did you do?

A. I became connected with Rush Medical College.

Q. How long have you been connected with Rush Medical College?

A. About eight years.

Q. In what capacity are you connected with that institution?

A. As professor of Pathology.

Q. What is the meaning of pathology?

10856 A. Well, pathology is generally defined as the study of disease, more particularly the causes and consequences of disease.

Q. Are you connected with the University of Chicago?

A. I am.

Q. In what capacity?

A. I am professor of Pathology there also.

Q. How long have you been connected with the Chicago University?

A. About four years, between three and four years.

Q. Are you in the general practice of medicine now?

A. No.

Q. To what are you devoting your entire time?

A. My time is devoted to investigation, principally.

Q. In what department?

A. More particularly in connection with the infectious diseases, such as scarlet fever.

Q. How long have you been engaged in that study?

A. During the last two or three years that my work has become limited in this way especially.

Q. Have you made any autopsies in connection with your
10857 work at the County Hospital?

A. I have.

Q. For what purpose?

A. In order to study the changes produced by disease during life.

Q. What class of diseases have you given particular attention to?

A. Well that work in the county hospital will include pretty much all sorts of diseases that are likely to appear in a hospital of that sort.

Q. How extensive has been this work?

A. Well, it has been fairly extensive. The County Hospital is a large hospital and I have been doing a larger share of the post mortems there for many years, about ten or twelve years.

Q. Have you made a special study of the so called germ diseases?

A. Yes sir, I have.

Q. Do these diseases caused by germs come within the scope of your study?

A. They do.

Q. Have you made any study upon typhoid fever and malarial fever from the standpoint of a pathologist and clinician? 10858

A. I have.

Q. Does the subject of pathology include the subject of bacteriology?

A. Yes sir.

Q. Have you given the question of study of bacteriology any consideration?

A. I have.

Q. To what extent, Doctor?

A. Well, to a considerable extent. In the first place I have studied bacteriology considerably, both here and elsewhere, and in the next place our work as pathologists makes it necessary to do bacteriological work all the time.

Q. Have you conducted your studies in any place outside of Chicago?

A. Yes sir, I have studied in Europe.

Q. What places in Europe?

A. In Sweden, and in Prague and in Berlin.

Q. What institutions there?

A. While in Sweden I studied at the University of Upsala. In Berlin I studied in the Hygienic Institute and in Prague in the Pathogical Institute.

10859 Q. How long were you in these different institutions?

A. I remained several months in each place.

Q. Conducting a special study?

A. Partly and partly general studies.

Q. In connection with the studies you have detailed, have you taken up the question of the proper diagnosis of fever of the kinds known as typhoid and malarial?

A. I have.

Q. Have you had any experience in the diagnosis of these fevers, either in the laboratory or at the bedside?

A. I have both.

Q. Have you studied these questions sufficiently to give an expert opinion on them?

A. I think so.

Mr. Jeffries: I object to the question for the reason it is for the court to determine as to the qualifications, as to whether or not he has studied them sufficiently to pass an opinion, and not for the witness.

Q. What is typhoid fever and its clinical diagnosis?

A. Well, typhoid fever is a febrial disease caused by bacillus and characterized by a fairly defined course during
10860 the first part of which the fever gradually rises until it
reaches a certain height at which it remains for a period of a week or two and then gradually declines. There are certain well marked intestinal symptoms, especially dioarhea and frequently also hemorrhage in typhoid fever. The clinical diagnosis of typhoid fever would be based upon the recognition of these symptoms that I have outlined, aided by certain methods of study of the blood and other matters.

In the case of the blood there may be obtained in typhoid fever the so called aggulutination of the typhoid bacillus, and that is used very extensively now as a diagnostic measure. In the early stages of typhoid fever it is possible to cultivate the typhoid bacillus from the blood and that is also becoming used as a means of diagnosis.

Q. What is intermittent fever and its clinical diagnosis?

A. Well, the term intermittent fever, is a rather general term, that indicates the general character of the fever. It means that the fever intermits completely at certain regular intervals, during which the temperature drops to the normal.

Its clinical diagnosis would be determined by regularly taking the temperature of the patient and thus demonstrat-
10861 ing that the fever is intermittent.

Q. What is remittent fever and its clinical diagnosis?

A. Well, in remittent fever which is also a general term the temperature is always above normal, but it falls at certain periods more or less regularly and its diagnosis would be determined by a careful study of the temperature of the patient.

Q. What is typho-malarial fever and its clinical diagnosis?

A. Well, strictly speaking typho-malarial would mean a disease in which there was both typhoid and malarial fever, at the same time, and the diagnosis would be made by demonstrating the presence of the malarial organisms in the blood and the typhoid bacillus in the blood or absolutely indicate that typhoid fever was present at the same time as malarial, but formerly typho-malarial fever was applied to diseases of a more indefinite character, the exact nature of which was not known, the general symptoms of the attack resembling in certain ways malarial fever and in certain ways typhoid fever, and so they called these attacks typho-malarial fever, without knowing whether they were typhoid fever or malarial fever, or both.

Q. Is typho-malarial a common fever in its true type?

10862 A. It is apparently an exceedingly rare disease because, so far as I know, there are only two or three cases recorded in medical literature of typho-malarial fever in which an absolute diagnosis has been made.

Q. What is congestive fever and its clinical diagnosis?

A. Well, I really do not know what congestive fever is. It is a term that has been handed down from the forefathers and it is now very rarely employed, except perhaps in certain parts of the country, more particularly in the south, where it is regarded as a type of the malarial fever but the exact disease meant where the term congestive fever is employed probably varies from time to time, or would probably be different from time to time, and different in one place from another place.

Q. What is simple continued fever?

A. I do not know that there exists any definite disease of that kind. Simple continued fever is another one of those terms that have come down to us and it indicates a rather mild form of fever of some kind, the exact nature not being known.

Q. Are remittent, intermittent, typo-malarial, congestive and simple continued fevers distinct types of disease and

10863 so recognized by pathologists, bacteriologists and clinicians?

A. No, they are not.

Q. What significance do you attach to these terms as applied to fevers when they appear in vital statistics?

A. I think that in a large percentage of the cases they mean typhoid fever.

Q. Assume that the number of deaths reported as occurring from typhoid fever in the city of St. Louis, as evidenced by the annual reports of the Board of Health of the City of St. Louis Health Department is as follows:

	1890	140
	1891	165
	1892	441
	1893	215
	1894	171
	1895	107
	1896	106
	1897	125
	1898	95
	1899	131
	1900	168
	1901	198
10864	1902	222
	1903	288

And assuming further that the number of deaths recorded in the same reports under the heading remittent, intermittent, typho-malarial, congestive and simple continued fevers is as follows:

1890	226
1891	296
1892	326
1893	284
1894	179
1895	155
1896	177
1897	172
1898	134
1899	148
1900	112
1901	80
1902	102
1903	91.

10865 Do the number of deaths reported as occurring from typhoid fever alone in the city of St. Louis properly represent in your opinion the total number of typhoid deaths actually occurring in that city?

A. No.

Q. What reasons have you for saying that they do not?

A. Because of the large number of deaths recorded under the heading of remittent, intermittent, etc.

Q. To what do you attribute the failure of these statistics assumed in the foregoing hypothetical question to properly disclose the number of typhoid fever deaths occurring in the city of St. Louis?

A. For the reason just given in answer to the previous question, namely that the number of deaths attributed to the malarial fevers so called is, in my opinion, excessive and that of course depends upon erroneous diagnosis by the physicians in St. Louis.

Q. Why is it that doctors apply the terms remittent, intermittent, typho-malarial, congestive and simple continued fevers to fevers that are recognized as being typhoid or malaria?

A. Well it is undoubtedly the result of the teaching laid 10866 down from the early periods where these different forms of disease, especially typhoid fever and malarial fever were not distinguished one from the other.

Q. Do you know of any city in the country where the death rate from malarial fever alone is as high as in the city of St. Louis as evidenced by the number of deaths as assumed in the hypothetical question under the heading intermittent, remittent, typho-malarial, congestive and simple continued fevers occurring in the reports of the Board of Health of the city of St. Louis?

Mr. Jeffries: Objected to unless the witness will qualify as being acquainted with the mortality records of the various cities throughout the United States.

A. No, I do not.

Q. Is malarial fever a prominent cause of death in this country?

A. No, it is not.

Q. What proportion of deaths in the column under the heading intermittent, remittent, etc., assumed in the foregoing hypothetical question as occurring in the city of St. Louis as evidenced by the reports of its Board of Health in your opinion should be classed as typhoid?

10867 A. Well, in my opinion it means that between 75 and 90 per cent. of those cases probably ought to be put in the typhoid column.

Q. What proportion as malarial fever?

A. From ten to twenty or twenty-five per cent. Of course this is a general opinion only.

Q. What do the mortality statistics of malaria show in cities where careful attention has been paid to malarial fever, as regards the number of deaths occurring from malarial fever?

Mr. Jeffries: Object to the question for the reason that it does not particularize the cities referred to.

A. They show but very few cases relatively speaking of deaths from malarial fever.

Q. Is it generally recognized by bacteriologists and pathologists and clinicians that classifying typhoid fever in one column, and intermittent, remittent, typho-malarial, congestive and simple continued fever in another column, in the board of health reports of cities, is an improper classification, from a scientific standpoint as affording a true indication of the mortality from typhoid fever and malaria?

10868 A. Yes sir, it is.

Q. Assuming that the reports of the board of health of the city of St. Louis, by the month, from 1895 to 1903, inclusive, under the heading typhoid fever, which for the purpose of convenience is designated "A" in the table and that intermittent, remittent, typho-malarial, congestive and simple continued fever for the sake of convenience is designated as "B" in the table that was prepared and sworn to by Professor Jordan, based upon said reports and is as given by him:

10869 Will you please state what construction you place upon this table as showing the relative mortality from typhoid fever and malarial fever in the city of St. Louis during the periods covered by the foregoing table?

A. Well, the tables appear to show that until the year 1900, when one of these diseases occurred in considerable numbers in a certain month of the year, the other disease occurred to about the same extent at the same time, whereas after 1900 the number of deaths from remittent and intermittent fevers, etc., is on the whole smaller than from typhoid fever.

Q. Assume that the added totals of tables from typhoid fever and the tables from remittent, intermittent, typho-malarial, congestive and simple continued fevers, as they appear in the reports of the board of health of the city of St. Louis is as follows:

	1890	361
	1891	381
	1892	767
	1893	499
	1894	350
	1895	262
	1896	283
	1897	297
	1898	229
10870	1899	279
	1900	280
	1901	278
	1902	324
	1903	379

What do these totals as above indicated represent in your opinion as to the mortality condition of typhoid fever in the city of St. Louis covering the period as above indicated after allowing in said remittent, intermittent, typho-malarial, congestive and simple continued fever column such proportion as being typhoid fever as in your opinion you should allow, what is your opinion as based upon the statistics as assumed in the foregoing hypothetical question as to typhoid death under the remittent, intermittent, etc., tables, in the city of St. Louis as to whether the said statistics show an increase or decrease in the typhoid fever mortality in the city of St. Louis since 1899?

A. The figures do not appear to me to show any increase in typhoid fever mortality.

Q. Assume that two circular letters one issued in the fall of 1900, and another one issued in the fall of 1901, were issued by the Health Commissioner of St. Louis calling the attention

10871 of physicians to the fact that the law required them to report all cases of typhoid and all deaths from typhoid and at the time that that letter was sent out, the question of the opening of the drainage canal was being agitated in the public press at St. Louis and there was a considerable discussion, and an investigation was going on at that time of the analysis of the samples of water collected, etc., and was attracting considerable attention. From your examination of the statistics at St. Louis, as heretofore assumed in the hypothetical question heretofore asked you, for the years 1900, 1901 and 1902, as compared with previous years, does the effect of such a letter, assuming that the same had been sent to the doctors by the health department of St. Louis, manifest itself in those statistics?

A. I think so.

Q. In what way does the effect of such a letter appear from the statistics?

A. It would seem to appear in the prominent increase in the number of deaths from typhoid fever, associated with a corresponding prompt decrease in the number of deaths from remittent, intermittent and other fevers.

Q. From your examination of the typhoid and typho-malarial groups of death as assumed in the foregoing hypo-
10872 thetical question, what is your opinion as to whether these two tables taken separately correctly show the typhoid condition of the city of St. Louis for the period mentioned?

A. In my opinion they do not correctly show the typhoid condition.

Q. Upon what do you base your opinion that they do not correctly show the typhoid conditions in the city of St. Louis taking them separately?

A. For the reason that I believe that a large percentage of the tables include under intermittent, remittent fevers, etc., what really were deaths from typhoid fever.

Q. From your knowledge of classes of fevers mentioned in the two columns of vital statistics as heretofore assumed, how should they be treated by a bacteriologist, a pathologist, clinician and statistician in order to arrive at the true typhoid fever mortality in the city of St. Louis?

A. I think they ought to be consolidated.

10873 Q. In what way should they be consolidated upon what percentage basis?

A. Well, in my opinion I think that the approximate truth could be arrived at by consolidating the two tables and then perhaps substracting ten per cent.

Q. Assuming that the table testified to in evidence by Professor Jordan as compiled from the typhoid fever mortality, the intermittent, remittent, typho-malarial, congestive and simple continued fever mortality, of the health reports of the city of St. Louis and based upon the population of the city of St. Louis for the years 1890 to 1900, according to the United States census reports and the intervening years estimated by Farr's formula, which table was prepared by Professor Jordan and testi-
10874 fied to by him, will you please state what in your opinion, based upon the tables hertofore read and assumed in the hypothetical question as to whether the typhoid fever has increased or decreased in the city of St. Louis since 1900 over the conditions that obtained in St. Louis prior to 1900?

A. Typhoid fever has decreased in the city of St. Louis since 1900.

Q. How did you arrive at that conclusion, Doctor?

A. Why, by studying the figures in the table.

Q. What do they show?

A. Well, they show that up to the year 1895, inclusive, the death rate from typhoid fever appears to be approximately 80 or 90 per cent. whereas after 1896 up to the period 1900 it appears to be between 50 and 55 per cent, that is the death rate appears to be between 50 and 55 per cent., and between 1900 and 1903 the death rate is about the same.

CROSS-EXAMINATION

By Mr. Jeffries:

Q. How long have you been engaged in the practice of medicine and in the work of instructing in colleges?

A. Since 1887.

Q. How many examinations of statistics have you been
10875 called upon to express an opinion as to the relative proportion of deaths from malaria as reported?

A. This is the first one.

Q. What is true with reference to malaria is also true with reference to all of the diseases allied with typhoid fever?

A. Yes sir.

Q. Whether they be remittent, intermittent, typho-malarial, or diseases of that character?

A. Yes sir, this is the first time I have been called upon to express any opinion in regard to questions of that character.

Q. When did you make an examination of the health reports of other cities in the United States so far as these particular diseases which you have testified about are concerned in comparison with the mortality records from those diseases in the city of St. Louis?

A. During the last few days and this morning.

Q. State what mortality records were examined by you?

A. Some of the records pertaining to Chicago, Baltimore and Albany, New York.

10876 Q. Is it not a fact, Doctor, that malaria is more prevalent and more malignant in the warmer climates than in the colder climates?

A. It is.

Q. I understood you to say that about from ten to twenty-five per cent. of the malaria deaths should be transferred to the typhoid deaths in the city of St. Louis?

A. No, that is a misunderstanding.

Q. What did you mean when you used those words?

A. I did not use those words.

Q. What did you mean when you said about from ten to twenty-five per cent. of the malarial deaths so reported were actual typhoid deaths?

A. Will you permit me to explain what I have said, that from 75 to 90 per cent. of the malaria deaths should be transposed, in my opinion, to the typhoid column.

Q. Why do you say that 75 per cent. of the malaria should be removed from the malaria column into the typhoid?

A. I say that in my opinion from 75 to 90 per cent. of the deaths in the malaria column of the St. Louis reports of 10877 health should be removed to the typhoid fever column because it seems to me that represents the actual condition of affairs more accurately.

Q. And that opinion is based upon the examining of health reports of the city of Chicago, Baltimore, Maryland, and Albany, New York?

A. And St. Louis together with such general knowledge of these subjects as I may happen to possess.

Q. And you give that opinion without reference to the source of the disease or the location of the patient?

A. No, those facts are taken into consideration.

Q. To what extent are those facts taken into consideration, Doctor?

A. In so far as on account of the location of St. Louis it occurred to me that it might be reasonable to suppose that the larger number of malignant cases of malarial fever might develop or be imported into St. Louis than into Chicago or Albany.

Q. And if there are importations, in determining the death rate in that city alone, they should not be carried over into the typhoid but should be separated should they not?

10878 A. I have reference to the malarial deaths. I meant that certain cases of malignant malaria might perhaps be imported into St. Louis from farther South, not typhoid.

Q. What percentage did you allow on that?

A. No definite percentage.

Q. You are just guessing at it?

A. Yes sir.

Q. Did you take into consideration the fact that malaria is more malignant and prevalent in the Mississippi River valley than it is at Albany?

A. I did.

Q. And at Baltimore?

A. I did.

Q. And at Chicago?

A. I did.

Q. Did you study the statistics for that proposition?

A. In a general way.

Q. State what you found in making this examination?

A. Well, we found in Albany that the number of deaths reported from malaria decreased very markedly after the establishment of a sand filtration of the water. At the same time there was a noticeable diminution in the number of deaths from

10879 typhoid fever so that it would appear as though sand filtration of the water very materially diminished the death rate from both typhoid fever and malaria. In case of Chicago it was noticeable that in the years of great prevalence of typhoid fever that is to say from 1899 to 1902 the largest number of deaths from intermittent, remittent and other fevers of that general character were reported from 1885 or something like that up to the present time.

Q. You found did you not in Albany, in Baltimore and in Chicago that the intermittent, remittent and the malaria followed in figures to a certain extent the prevalence of the typhoid?

A. It so appeared, yes; whereas in Baltimore, if I may go on and add this to my previous answer the number of deaths from malaria fever as reported, steadily diminished during the last few years.

Q. That is in Baltimore?

A. Yes sir.

Q. Had those fevers diminished in reality or is the decrease simply shown in the report and based upon a better an-
10880 alysis and diagnosis of the case?

A. I think the latter.

Q. And that is true of Chicago and Albany?

A. I could not say as to that.

Q. In making comparisons would you make the same percentage or allowance in a southern city as in a northern or in a city located in territory where malaria was more prevalent than in a city where it was less prevalent?

A. No, I would not.

Q. Have you ever personally examined the condition at St. Louis?

A. I have not.

Q. Have you ever personally made any diagnosis of cases of disease in the city of St. Louis?

A. The only thing I ever did in the city of St. Louis was to make a post mortem.

Q. That was in one particular case?

A. Yes sir.

Q. That was a poison case was it not?

A. I think so.

10881 Q. Do you know whether or not for the years 1897, 1898 and 1899 a similar letter was sent out by the health department as that referred to by Mr. Todd in his question as having been sent out by the Health Department of the City of St. Louis in 1900?

Mr. Todd: I object to the question on the ground that the question that I put was a hypothetical question, assuming what was testified to in this case and the testimony as to whether a similar letter was sent out or not is a matter that is all in the record of this case, in the testimony by Professor Teichmann, and it is not competent as this question put to the witness on cross examination assumes the fact that a letter was sent out.

A. I do not know anything about any such letter.

Mr. Jeffries: In the event that letters of this character were sent out for these years would they have the effect detailed by you in your answer to the question put by Mr. Todd, assuming that a letter of that character had been sent out?

Mr. Todd: I object to the question on the ground that the testimony of Professor Teichmann given in this case states that no such letter was sent out, except the two assumed in 10882 this testimony and it is improper for the counsel to assume in a hypothetical question the sending out of letters when the evidence in the case discloses to the contrary.

A. They might.

Q. And they might not?

A. Yes sir.

Q. And the same is true with reference to the letter referred to by Mr. Todd in his question?

A. Certainly.

Q. Is it not a fact that the physician in charge of each particular case by reason of his ability to observe the symptoms of the disease is better able to determine the nature and character of that disease than a person is who undertakes to diagnose the cases from the statistics?

A. In regard to individual cases, certainly.

Q. And that applies to each and every individual case?

A. Yes, assuming, of course, that the physician uses the modern means of diagnosis exhaustively.

Q. The opinion which you have expressed in your direct testimony upon the actual typhoid conditions in the city 10883 of St. Louis for the last six years are based upon examination of the health report of the four cities just previously mentioned by you, and by making the per cents of them?

A. Yes, and in addition such general knowledge as I have of typhoid and other diseases.

Q. What general knowledge in the main do you refer to?

A. Well, I refer directly to this well known fact, namely, that deaths from malaria fever in temperate climates are exceedingly few and far between and to the further fact that so far as is known the prevalence of fatal malaria in St. Louis and in the vicinity of St. Louis has not been marked for many, many years.

Q. You recognize the fact do you not that people die of malaria fever?

A. I do, yes sir.

Q. But in expressing your opinion upon typho-malaria, intermittent, remittent and other deaths from other diseases in the city of St. Louis, where did you obtain the information or statistics upon which your opinion is based?

A. The statistics which I had are these that have been brought forward here this morning.

Q. You considered only such as that contained in the 10884 question that was put to you calling for your opinion?

A. I interpreted those statistics of course in the light of my general knowledge in regard to those diseases and in the light of what I happened to know about those diseases in other places.

Q. Those statistics that were read to you in the question were the only ones considered?

A. Those were the ones that I was asked to interpret, yes sir.

Q. Now, did you make an examination of the health reports yourself or take for granted such as was given you by the question or shown you by some one else?

A. I did not examine any health reports personally.

Q. Either of St. Louis, Chicago, Baltimore or Albany?

A. No sir.

RE-DIRECT-EXAMINATION

By Mr. Todd:

Q. All the statistics to which you addressed your answers on direct examination were contained in the hypothetical question propounded to you and assumed by you to be true?

A. Yes sir.

Adjourned until 2:00 P. M. same day.

2:00 P. M., Thursday, February 25, 1904.

10885 Continuation pursuant to adjournment.

Present, the Commissioner, and same counsel representing the respective parties.

PROF. E. G. HASTINGS

a witness called on behalf of the defendants, being duly sworn, testified as follows:

Direct Examination

By Mr. Todd:

Q. What is your name?

A. E. G. Hastings.

Q. What is your business?

A. Instructor and investigator in bacteriology.

Q. Where?

A. University of Wisconsin.

Q. How long have you been there?

A. Since July, 1899, with the exception of one year which I was away studying.

Q. Where?

A. In Germany.

Q. At what place in Germany?

A. I studied in Munich.

10886 Q. Where did you graduate before taking up the post graduate course?

A. Ohio State University.

Q. After graduating what did you do?

A. Spent one year in post graduate work in the University of Wisconsin.

Q. And then went abroad?

A. No, I was connected then with the University of Wisconsin for two years and abroad one year. Since then I have been with the University of Wisconsin.

Q. Are you connected in any way with Professor Russell?

A. Yes sir, I am assistant under Prof. Russell.

Q. Did you have anything to do with the experiment conducted with typhoid bacilli by Professor Russel at Averyville?

A. Yes sir.

Q. State what you had to do with this experiment?

A. Why, the inoculations of the tubes which were exposed in the Illinois River at Averyville were made by me and all samples taken by me and the plating of these samples in the nutrient media was made by me and all of these isolations from these plates were made by me.

10887 Q. Was this done under the direction of Professor Russell?

A. Yes sir.

Q. At what point were these tubes placed in the Illinois River?

A. Immediately above the Averyville bridge.

Q. What kind of tubes were these that you employed in this work?

A. They were parchment paper.

Q. By whom prepared?

A. The tubes were prepared by me. The parchment tubing, a portion of it was obtained from Professor Jordan of the University of Chicago, and the rest was obtained from the University of Wisconsin, at Madison.

Q. Just state how these tubes were prepared?

A. The tubing was cut into the desired lengths.

Q. State the length?

A. The tubes were of two sizes, the tubing that we obtained from the University of Wisconsin was about 15 inches in length. The other tubing which we obtained from the University of Chicago was of a greater diameter and the tubes were made shorter, about 10 inches in length. This includes the length of the tube which was to contain the water. The bottom

10888 was folded up and the length would be six inches greater than the dimensions given.

Q. Were the germs that you got from Professsor Jordan ones that have been testified here by Professor Russell and Professor Jordan as strains typhoid "X," "Y" and "Z"?

A. Yes sir, these were the cultures which were sent to me by Professor Jordan and the ones which were inoculated into the tubes and exposed in the river.

Q. Just describe the manner in which this inoculation took place?

A. The typhoid cultures were grown upon media agar for 24 hours and the growth was then removed from these and suspended in water. From this suspension of the organism the tubes were inoculated, each tube containing 200 cc. of the river water and inoculated with varying quantities of suspensions of the typhoid organism.

Q. What quantities of organisms were used in these various tubes, varying between what numbers?

A. Approximately 500 per cc. up to 10,000 per cc.

Q. Now, after the tubes were inoculated, what did you do with them?

A. They were then exposed in the river at the station above named.

10889 Q. How were they exposed?

A. They were placed in the containers in which the tubes were exposed, these were of metal galvanized iron pails.

Q. Describe these containers that you speak of?

A. They were provided with a top of strong wire cloth and also the sides of the pails for about two-thirds of this entire circumference were made up of this wire cloth, to allow the water free access to the tubes. The pails were provided with hasps and pad locks.

Q. What were these containers made of?

A. Galvanized iron.

Q. Just state how they were placed in the water, whether they were completely submerged or not?

A. They were completely submerged.

Q. How many sacs were employed in this experiment, containing typhoid bacillus?

A. 14.

Q. How many sacs were used that did not contain typhoid?

A. There were two control sacs which contained no typhoid There were two sacs that contained a sample of urine which
10890 were sent to me, which at the time that it was sent, they thought contained a large number, but on examination at the University of Chicago contained practically no typhoid.

Q. How were these sacs designated?

A. Well, the pails were marked and the sacs were designated by consecutive numbers from 1 up. There were two containers and each container was marked as I say, and the sacs were designated by the numbers.

Q. They were numbered from 1 to what?

A. 1 to 18.

Q. Now, after the sacs were placed in the water what did you do?

A. The samples were taken from the sacs at intervls.

Q. After the samples were taken from the sacs at intervals what was done with them?

A. The samples were immediately taken to the laboratory and plated out on the medium which was used.

Q. What media did you use?

A. The Drigalski medium entirely.

Q. Now, after plating it out on the media what did you do?

A. The plates were then incubated for 24 hours at 37½
10891 degrees Centigrade.

Q. At the end of 24 hours what did you do?

A. The plates were then removed from the incubator and worked over and the suspicious colonies were marked, and later these colonies were fished off into subcultures and the plates were then incubated at room temperature for 24 hours again and then worked over.

Q. What do you mean by working over?

A. An examination of the plates to pick out the suspicious or typhoid like colonies.

Q. What are the typhoid like colonies that you picked off?

A. Any organic colony which has the appearance of a typhoid colony.

Q. What are the appearances of a typhoid colony?

A. Upon this special media the colonies have a peculiar irridescence, a peculiar granular structure.

Q. Any other marks of identification you employed?

A. The colonies are always blue. They are never surrounded by a red zone. 10892

Q. After these colonies were picked off what did you do with them?

A. They were inoculated in tubes and these tubes immediately sent to Madison, or after an incubation of 24 hours sent to Dr. Russell at Madison.

Q. How was the record kept of these tubes, samples, plates and colonies, and by whom was it kept?

A. The records were kept by me. The tubes were, as I have said, each given a number and upon plating this number was placed upon the label on the plate, and in fishing the colonies from these plates the organism was given a consecutive number, which was followed through each one of the strains, "X," "Y" and "Z."

Q. And after you had done what you have indicated, how did you ship them to Professor Russell?

A. These tube cultures were then shipped to Professor Russell by express. They were packed and shipped to Professor Russell by express.

Q. Did you do anything with the agar blocks?

A. To some extent, yes sir.

Q. At Peoria?

10893 A. Yes sir.

Q. State what you had to do with that part of the experiment?

A. Agar blocks were inoculated with the cultures of the typhoid organisms and were then exposed in small metal containers which were placed in the large metal containers before mentioned and at intervals one of these blocks would be removed and cultures made from it, and the organisms which were isolated were also sent to Madison.

Q. State how these agar blocks were inoculated with the typhoid bacilli?

A. They were simply inoculated with what we call stab culture. A straight platinum wire which contained a growth of the organism on the end was thrust into the agar blocks and they were sealed on top by a nail which was heated so as to melt a small portion of the agar at the place where the stab was made to seal it.

10894 Q. How large were these agar blocks that were employed in this experiment?

A. Oh, they were an inch and a half long and half an inch square, in sections.

Q. After you took samples from the agar block what did you do with them?

A. The cultures were made from these agar blocks and these cultures were sent to Madison for Dr. Russell.

Q. Was any effort made to identify the colonies as typhoid bacilli at the laboratory in Peoria?

A. No sir.

Q. That part of the experiment was conducted at Madison, Wisconsin?

A. Yes sir.

Q. After these sacs were suspended in the water did any formation appear upon the sacs?

A. Yes sir.

Q. Describe the nature and character of that formation?

A. Within two or three days after the sacs were exposed they became dotted with small particles of mud. These gradually increased in size until at the end of about nine or ten
10895 days they would be as large as a half a dollar. At this time some of the sacs broke. This deposit of mud on the sacs was occasioned by the growth of a fungus which gave lodgment for the fine soot which the river water was carrying. This fungus gradually attacked the walls of the tube and weakened it so when the tubes were removed from the water the weight of the contained water was sufficient to break the wall in the weakened places.

Q. How did you ascertain the integrity of the sacs when they were in the water?

A. At the time the sacs were filled and closed they were then tested as to their tightness as to whether they would leak the water.

Q. After a sac disintegrated in the water what did you do with it?

A. After the first of the sacs broke, the remainder were then transferred to fresh sacs.

Q. After they were broken the remainder was transferred?

A. No sir.

10896 Q. Just explain what you mean by that?

A. After the first sac broke this gave evidence that the rest of them would not last very long, so in order to continue the experiment the remainder of the sacks of that series, the water in the remainder of the sacs of that series were transferred to fresh sacs.

Q. And the experiment continued in fresh sacs?

A. In fresh sacs.

Q. Were any of the sacs wherein the water was transferred broken before the transfer?

A. No sir.

Q. And after the transfer of the water from the sacs to the new sacs, did you make an examination of the old sacs to see whether they were intact or not?

A. Yes sir, they were still intact but the walls were very much weakened by the growth of this fungus.

Q. How did you ascertain that that was a fungus?

10897 A. A microscopic examination.

Q. You made an examination of it?

A. Yes sir.

Q. As often as you took samples from each one of those sacs you kept a record of it?

A. Yes sir.

Q. And did you turn over to Professor Russell a correct record of all you did at Peoria under his directions?

A. Yes sir.

CROSS-EXAMINATION, by Mr. Jeffries.

Q. How many sacs did you say you used in the experiment?

A. 18 in all.

Q. During that entire experiment how many sacs were broken on account of deterioration in the water?

A. I could not say.

Q. As many as half a dozen?

A. No sir.

Q. Well, what would you say as to the average?

A. As I recall the first time that any sacs broke was when two of them broke when the container was removed from
10898 the water and the water in the rest of the sacs was then transferred to fresh sacs and the old sacs were destroyed.

Q. Did the control sacs deteriorate more rapidly than the others?

A. No sir.

Q How many days were those sacs in the water before the break was noticed?

A. The first one broke in ten days.

Q. As soon as one sac was broken the contents of all the sacs were changed into new sacs?

A. Yes sir. As I said before we had two samples of tubing, one of which resisted the attack of the fungus longer than the other.

Q. Both samples of tubing were parchment tubing were they?

A. Yes sir.

Q. Any difference in the weight of the parchment?

A. I don't think so; not that I am aware of, any appreciable difference in the weight.

Q. How do you know that one had more resisting power than another?

A. As I say one was a sample of tubing that we obtained
10899 from Madison and broke in nine days while the first one of the sacs was tubing obtained from Chicago which broke in twelve days after they were exposed to the water.

Q. How many days did you carry on the experiment?

A. Cultures "Y" and "X" were continued for seventeen days; "Z" for twelve days.

Q. What was the reason you did not continue the "Z" strain for the full 17 days?

A. The sacs inoculated with the culture "Z" were not put in the water at the same time as the others, but later.

Q. How long did you keep the sacs out of the water when you were transferring the contents from the old to the new?

A. Half an hour.

Q. How long did you keep the sacs out of the water when you were taking the samples of water from them?

A. Fifteen or twenty minutes.

Q. How many samples did you take from each sac?

A. I could not say.

Q. Well, approximately,—you have some idea, have you not?

A. Well, an equal number of samples were not taken from each sac.

Q. On an average how many times was each sac removed from the water?

A. Whenever the container was removed of course the sacs which were exposed in that one container were removed from the water. 10900

Q. Well, how often was the container removed?

A. In the case of "Y" and "X" I should say about ten times and in the case of "Z" it would be about six times.

Q. And those were the only times that it was removed?

A. Yes.

Q. Then in case of "Z," there were only six samples of water taken from the sacs?

A. They were sampled at six different times. More than one sample taken.

Q. How many samples were taken from Strain Z?

A. I should say about 18.

Q. Then there were 3 samples of water taken from strain "Z" each time the container was removed from the river?

A. Yes, approximately.

Q. How much water was contained in each one of those samples?

A. From 7 to 10 cc.

Q. Now, how much of the sample was plated?

A. Varying quantities. At first smaller quantities. Three plates were usually made from each sample. These plates were made with varying quantities. The first series of plates were usually made with 1-20, 1-100 and 1-2000 of the cc. and as the experiment continued the amount of water seeded in each plate was gradually increased as the germ contents of the sac was diminished. 10901

Q. What part of the sample did you use in the plating of the "Z" strain?

A. 1 cc.

Q. And the last plating of the "Z" strain?

A. Yes sir.

Q. Now, was that 1 cc. divided into 3 plates? Or was there 1 cc. on each plate?

A. The largest amount ever used was 1 cc. in the single plate. It was the maximum amount.

Q. And when was that?

A. That was at the end of the experiment.

Q. On strain "Z"?

A. On strain "Z" as well as on strain "X" and "Y."

Q. Why was not 1 cc. of water used in each experiment?

A. Because the germ content of the water was too high; the plates would be so thickly seeded that nothing could be done with them.

Q. Why could not something be done with them?

A. The colonies would be so thick and so small that they could not be seen with the naked eye.

10902 Q. In other words you could not discover them on the plates?

A. Yes, you can see very fine colonies but you can not make subcultures from them.

Q. Does not the character of the plates used by you suppress nearly everything except the typhoid and kindred colonies?

A. I do not know as to that.

Q. Did you at any time make more than three platings from any one sample of water taken from the sac?

A. In a few instances four plates were made.

Q. In what instances were four plates made with reference to the strain and what number if you know?

A. I could not tell as to that.

Q. Why did you make the fourth plate?

A. Sometimes more samples were taken than others. My apparatus was limited and those times in which fewer number of sacs were sampled there were more plates available and more incubator room available for plates.

Q. Do you know of your own knowledge where these strains came from, other than that which you have just stated?

A. No sir.

Q. How long after the sacs were removed from the water and the samples taken from those sacs before the samples of water were plated?

A. From 1 to 2 hours.

10903 Q. In what were the samples of water kept after being removed from the sac and before plating?

A. In glass tubes.

Q. Did you in any instance dilute the samples or the quantities of water plated?

A. Yes sir.

Q. How soon after the samples of water were taken from the sacs was the diluting substance added?

A. From 1 to 2 hours.

Q. The dilution would not be made until just before plating?

A. Just before plating.

Q. Did you examine the interior of the sac to determine whether or not any substance formed upon the wall?

A. Yes sir.

Q. Was there any substance, any formation of any kind upon the wall of the sac upon the interior?

A. Not on the interior, no sir.

Q. How did the interior of the sac compare with the exterior after four or five days submergence in the water?

A. The fungus has begun to grow upon the walls and 10904 these particles of soot begun to find lodgment on the walls of the sac on the exterior while the interior of the sac was still dry.

Q. The water that was in the sac was taken from the river at the point where the sacs were submerged?

A. Yes sir.

Q. Do you know whether that water contained any fungus or any soot of any kind, I mean the water that was contained in the sac?

A. It contained some silt, if the river was slightly turbid at that time.

Q. How did you make those determinations as to the silt contents of the water in the sac?

A. No determinations were made.

Q. You judged that because of the turbidity of the water and because of the silt formation upon the exterior of the sao did you?

A. Yes sir.

Q. You used the same precaution each day in removing samples of water from the sac in the conveyance of those samples to the laboratory and in the laboratory experiments did you not, from one end of the experiment to the other?

A. Yes sir.

10905 Q. How many colonies on an average did you pick off the plates, if you know?

A. I could not say as to that.

Q. Is it not a fact that upon some plates the number picked off was not more than three?

A. Yes sir.

Q. Now, state why only that number was picked?

A. It was largely a matter of chance, as when the plates were worked over suspicious colonies were then fished off and subcultures made.

Q. In making these selections or in picking the colonies off the plate it is a delicate and difficult matter?

A. I do not understand the import of your question.

Q. A delicate and difficult matter in making the selections of those colonies which have the appearance of being typhoid?

A. It is a matter that would require certain experience and judgment, not necessarily delicate.

Q. And often times you are mistaken in your judgment are you not?

A. Yes sir.

Q. And pick off numerous colonies that have the appearance of being typhoid which are not?

10906 A. Yes sir.

Q. And often times great numbers of the same colonies or colonies which have the same appearance as those which have been selected and which in your judgment were characteristic of typhoid colonies remained upon the plates unfished?

A. Yes sir.

Q. About how many colonies would form upon these plates, using 1 cc. in the experiment, at the time 1 cc. experiments were used?

A. From 100 to 200.

Q. At the time .01 of a cc. of water was analyzed how many colonies would appear upon a plate?

A. With these varying quantities of water were used so as to get plates with which it was possible to work.

Q. Then you used varying quantities in every determination, did you?

A. Yes sir.

Q. The first bacterial analysis or plating from the first sample of water that was taken, was made with 1 cc., .1 and .01 of a cc.?

A. No sir, not the first sample.

Q. How was that made?

A. Made with 1-20, 1-100 and 1-2000 of a cc.

10907 Q. Now, how many colonies would appear upon one .002 of a cc.?

A. Well, that would vary, from time to time.

A. Well, approximately, with reference to this experiment, what was the result as shown by the colony counts?

A. At first the samples were taken 24 hours after the sacs were inoculated. The germ content would vary with the different series. I recall they ran about 100 colonies, from 4 to 200 colonies, on each plate.

Q. That is, on the one .002?

A. Yes sir.

Q. And with an increasing number, according to the quantity used?

A. Yes sir.

Q. How large are those plates?

A. They vary in size.

Q. Were not all the plates you used, the same size?

A. Not exactly. The average plate is from 3½ to 4 inches in diameter.

Q. Were any that you used larger than that?

A. Than four inches?

Q. Than four inches square?

10908 A. Four inches in diameter.

Q. That is both ways.

A. The plates are circular.

Q. Are they all circular?

A. Yes sir.

Q. Were those sacs submerged with water all the time except when the samples of water were being taken from them, or whenever the contents were being transferred to fresh sacs?

A. Yes sir.

Q. And were the sacs kept full of water all the time?

A. No sir, they originally contained 200 cc., and as the samples were taken of course the contents diminished by the amount of samples taken.

Q. And that left a vacancy in the sacs?

A. Yes sir.

Q. Was the mouth of the sac tied down, then, so as to keep the contents full and solid, all the time?

A. No sir.

Q. After you removed the sample from the sac, what did you do with the sac?

A. The sac was then closed up, and returned to the container.

Q. Closed in what way, and in reference to the organic contents of the water?

10909 A. They were closed with heavy clamps at the top, and the original length of the sac was maintained, I mean, the portion which was emptied, so as not to shorten it up by that much.

Q. Then it left a portion of the interior of the sac vacant?

A. Yes sir.

Q. Is that true?

A. Yes sir.

Q. How large, at the latter end of the experiment was the space on the sac that was vacant?

A. It would vary, to the amount of water that was removed from under one sac.

Q. Taking the measurement of the stick into consideration, how would the vacant part compare with the part that was filled with water?

A. I should say it would be about half of the water in some of the sacs, or about one-third of the water, in some of the sacs, was removed in the samples taken.

Q. Now, was the clamp in the sac pushed down to the water?

A. No sir.

Q. Were those sacs suspended in the water?

A. Yes sir.

Q. In what way?

A. They were simply suspended from wires which ran
10910 across the top of the metal containers, by clamps, with
which they were closed at the top.

Q. Were they in a position that they could swing in the water, or were they kept stationary?

A. They could swing to a limited extent.

Q. How much?

A. As far as the metal container would allow them to do so.

Q. Well, how much would that container allow them to swing?

A. The containers, I believe, were 13 inches in diameter.

Q. And all those sacs were put into containers?

A. Yes sir.

Q. Well, did the containers swing, or were they stationary?

A. It was somewhat suspended in the air.

Q. Suspended from above?

A. Yes sir.

Q. And how deep in the water was the container?

A. So that the sacks were from 6 inches to a foot beneath the surface of the water.

Q. Well, you don't know whether it remained stationary or not, after it was suspended from the water?

A. There was probably some motion, according to the motion of the water.

10911 Q. What did you put these colonies in, when you fished
them off the plates?

A. In plain nutrient agar, or glucose agar.

Q. Where was that prepared?

A. Madison.

Q. And sent to you?

A. Yes sir.

Q. Or did you take it down there with you?

A. It was sent to me.

Q. What temperature was it kept at, after the colonies were fished and deposited on it?

A. As I said before, some of them were immediately sent to Madison after they were inoculated, and others were inoculated for 24 hours at 37½ degrees before sending them to Madison.

Q. How long was it from the time you picked the colonies off, before they were deposited in this media?

A. A fraction of a minute.

Q. Just as rapidly as it could be done?

A. Certainly.

Q. How long did you keep them there before you started the contents on to Madison?

A. As I say, some of them were inoculated for 24 hours before being shipped, others were started the same day as the inoculations were made. 10912

Q. Were they duplicates?

A. Those were kept there.

Q. Were those duplicates of those that were shipped?

A. No sir.

Q. Some of them you inoculated for 24 hours, and some you did not?

A. Yes sir.

Q. Now then can you state which ones were incubated by you, and which were not?

A. No sir.

Q. Have you any means of telling?

A. No sir.

Q. Did you notify Prof. Russell which had been incubated and which had not?

A. Yes sir.

Q. At the time of the incubation?

A. Yes sir, the time was always 24 hours.

Q. Were those that were incubated sent to him along at the same time as those that were not?

A. No sir.

Q. All different times?

A. Different times.

10913 Q. Now did that rule hold good throughout the entire experiment?

A. Yes sir.

Q. For instance, you were picking colonies from three plates representing a certain sample of water taken upon a certain day. Now, would all those be incubated?

A. They would all be incubated or not.

Q. Do you know how many samples you incubated, or how many plates you incubated?

A. No sir.

Q. Or do you know the number of times that the colonies picked from the plates were incubated?

A. No sir.

Q. Do you know the proportion of the total that were incubated?

A. No sir.

Q. Do you know the proportion of those that were not incubated?

A. No sir.

Q. At the time samples of water from the sac were plated upon from one to three plates, the colonies fished off by you were sent to Professor Russell, without incubation?

A. More than one plate was always made, two at least, never less than two.

Q. The plates representing that particular sample of 10914 water taken from the sac, was picked, or fished off the the typhoid colonies, and those colonies as fished were sent to Dr. Russell without incubation?

A. Yes sir.

Q. How did you send them?

A. By express.

RE-DIRECT EXAMINATION, by Mr. Todd.

Q. Did you send with these colonies, any memorandum to Prof. Russell, showing whether they had been incubated or not?

A. Yes sir.

Q. How did you keep that memorandum of samples that were incubated and those that were not incubated?

A. I simply advised him by letter as to whether the samples had been incubated or not.

Q. Did you keep any memorandum in the laboratory of the samples that had been incubated, and those that were not incubated?

A. Not any data as to that particular point, no sir.

Q. When you communicated with him by letter, how 10915 did you designate the samples that had been from those that had not been incubated?

A. Well, all of the shipment on any one day would either have been incubated, or would not have been incubated.

Q. How was that fact made known to Prof. Russell?

A. I would make a shipment on a certain day and advise him by letter that samples which I had shipped with certain consecutive numbers had been incubated. Each subculture was given a consecutive number.

Q. You haven't those letters with you, have you?

A. No sir.

Q. So that Prof. Russell was advised at each shipment of the samples, those that were incubated, and those that were not?

A. Yes, I say each shipment was either, or rather had been incubated, or had not been incubated.

RE-CROSS-EXAMINATION, by Mr. Jeffries.

Q. In your opinion what proportion of the colonies fished, were incubated by you before shipment to Professor Russell?

A. I should say about one-third.

Q. Were incubated?

A. Were incubated before shipment.

10916 Q. And two-thirds were not incubated?

A. Two-thirds were not.

(Signature Waived.) F. S. B., Com'r.

ELIHU B. SPENCER,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Mr. Todd, and testified as follows:

Q. What is your name?

A. Elihu B. Spencer.

Q. What is your business?

A. Photographer.

Q. How long have you been in that business?

A. About thirty-five years, I guess.

Q. Are you employed by the Sanitary District?

A. I am.

Q. How long have you been employed by the Sanitary District?

A. A little over three years.

Q. Have you taken any pictures of views on the Illinois 10917 River, from La Salle to St. Louis?

MR. JEFFRIES: I object to it as immaterial.

A. I have.

MR. TODD: Q. When did you make the first set of photographs along the Illinois River?

A. In July, 1902.

Q. Have you prepared an album showing the places where you took the pictures?

A. I have.

Q. Will you produce that album?

A. This one, this series was taken in July, 1902.

Q. At what points were those pictures taken?

A. They are designated on each picture.

Q. Are those pictures true representations and photographs of the places they purport to represent?

A. They are, that section which shows in the picture.

Q. At the time these pictures were taken, what were the stages of the Illinois river high, or low?

A. High.

MR. TODD: I offer this album, containing 39 views, from the Eads Bridge of St. Louis, to Henry, along the Illinois River, and ask to have it marked Defendant's Spencer's Exhibit A.

10918 MR. JEFFRIES. I object to it as incompetent, irrelevant and immaterial.

Said exhibit, received in evidence, and so marked by the Commissioner.

10919 MR. TODD: Q. Did you make any other views?

A. I did, in April, 1903.

Q. What were the stages of the river in April, 1903, when you made these views?

A. High water.

Q. Are those true and correct representations of the places photographed?

A. They are.

Q. Between Hardin, on the Illinois River, and Henry on the Illinois river?

A. They are.

MR. TODD: I offer this album, consisting of 46 photographs, and ask to have it marked Defendant's Spencer's Exhibit B.

MR. JEFFRIES: I object to the offer for the same reason as stated in the objection to the introduction of the preceding album, as incompetent, irrelevant and immaterial.

Said exhibit received in evidence and so marked by the Commissioner.

10920 MR. TODD: Q. Did you make any other views?

A. I did, in July, 1903.

A. At the time in July, 1903, when the photographs were taken, what was the stage of the Illinois river?

A. Lower water.

Q. Are those photographs, 52 in number, in this album, true and correct representations of the places they purport to represent?

A. They are.

MR. TODD: I introduce in evidence this album taken in July, 1903, of photographs along the Mississippi River, from St. Louis to Henry, and ask to have it marked, Defendant's Spencer's Exhibit C.

MR. JEFFRIES: I object to it as incompetent, irrelevant and immaterial.

Exhibit received in evidence and so marked by the Commissioner.

No Cross-examination.

Signature waived.

F. S. B., Com'r.

Adjourned until 10 a. m., February 26, 1904.

10921 10:00 a. m., Friday, February 26, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same consel representing the respective parties.

PROF. ERASTOS G. SMITH,

a witness called on behalf of defendants, being duly sworn, testified as follows:

DIRECT EXAMINATION, by Mr. Todd.

Q. What is your name?

A. Erastos G. Smith.

Q. What is your business?

A. I am now Professor of Chemistry at Beloit College, Beloit, Wisconsin.

Q. How long have you been connected there, Professor?

A. Since 1881.

Q. From what college did you graduate?

A. Graduated from Amherst College in 1877 with the degree of A. B.

Q. After graduating, what did you do?

A. I studied medicine for a year under the private tutilage of Dr. A. F. Reed of Massachusetts.

10922 Q. Then where?

A. I was then called as instructor in chemistry in Williston Seminary, East Hampton, Mass.

Q. How long were you there?

A. Three years.

Q. And from there where did you go?

A. From there I was called to the professorship of chemistry and mineralogy at Beloit College.

Q. And have been there ever since?

A. Yes, sir, except for an absence of about eighteen months when I was in Europe studying at the Georgia Augusta University in Germany, where I took my degree of Doctor of Philosophy in August, 1883.

Q. What line of studies did you pursue in Europe?

A. Chemistry and mineralogy.

Q. Have you been connected with any institutions except those which you have already outlined?

A. I took a course in bacteriology one summer at the Massachusetts Institute of Technology in Boston.

Q. Have you pursued the study of bacteriology since
10923 taking the course at the Boston Institute of Technology?

A. I have.

Q. Where?

A. Not under direction—I studied it at home. I have a laboratory of my own, a private laboratory known as Beloit Sanitary Laboratory, where studies of this kind are carried out. It is particularly devoted to studies of this character.

Q. Have you taught bacteriology?

A. I have not.

Q. What experience have you had in sanitary work?

A. I have given practically all of my available time since about 1885 to the study of sanitary problems, especially water courses.

Q. What water courses have you investigated?

A. In the course of my study and investigations I have been called to the study of many public water supplies, including the study of supplies from the ground or ground wells or artesian wells, rivers and lakes and impounded reservoirs. These would naturally include the lakes and rivers and streams tributary thereto.

I have also done considerable work upon the Platte river, the Missouri river, the Mississippi river, the Schuylkil river, the Delaware river, Beaver river, Pennsylvania, and other smaller streams.

10924 Q. Relate briefly what work you did on these different streams you have investigated?

A. The work done upon these streams has been the observation of the sanitary qualities of the water and its adaptability for drinking and domestic purposes and its suitability for water supply. These embraced both chemical and bacterial work, the bacteriological work having been done the last six or seven years; before that most all, practically all of it, was chemical work.

Q. Have you made a special study of sanitary problems?

A. I have devoted about all of my available time since about 1885 to this class of problems.

Q. Have you investigated any typhoid fever epidemics?

A. I have.

Q. Which ones?

A. I have investigated the typhoid fever epidemics at Baraboo, Wisconsin, Ashland, Wisconsin, West Superior, Wisconsin, Menominee, Michigan, and Rock Island, Illinois, and have frequently been called in where typhoid fever was alleged to be present.

Q. Will you relate the cases and the results of the
10925 investigations of the epidemics which you have made?

A. Two of these were, in my opinion, directly attributable to the character of the water supply, namely the one at Baraboo and the one at Rock Island. In the others the water supply, in my opinion, was not so directly responsible for the outbreak.

In the one at Baraboo, which occurred in 1902, the outbreak was due, in my opinion, clearly to fault in the water serivce. There were some cases of typhoid fever present in the town, and that lead to an investigation of the water supply. Dr. Russell of Madison was called there by the Board of Health, and the Baraboo Water Company asked me to come there and investigate the problem for them. We found that there had been a considerable number of cases in the town and we were at first at a loss to account for their cause. Finally it was agreed upon, by Dr. Russell and myself that we would tabulate results and see what results could be obtained. Upon tabulating these returns of typhoid fever cases we found that they fell into two groups, that upon successive periods there seemed to be an increase in
the number of cases. This lead to inquiry upon our part
10926 and we found that, allowing for the ordinary period of
incubation of the disease, (about 13 to 17 days) upon tracing back from the crest of the wave of the extent of the disease, we found that at a period about two weeks before a steam pump had been started as an auxilliary to the water supply, and we came to the conclusion that the starting of the steam pump had produced an extraordinary draft upon the mains which tended to open some joints in the pipes which lay under the canal, which in turn received the sewage from the city ofBaraboo. It was shown upon further experiments that this was the case, and that lead to the removal of that pipe and its being

replaced by a pipe that was intact, after which the epidemic died down. In my opinion that epidemic was due to the defective conditions of the water pipe over which the canal water flowed, which in turn received the sewage from the city of Baraboo.

I would say that I was upon the ground a part of the time and the details of the work were carried out by my assistant, in consultation with me.

The case at Rock Island was, in my judgment, due to the condition of the water supply. In 1901, I think the last of February, I received a letter from one of my former students, a Mr. Albee, who was at that time instructor in Chemistry 10927 at Rock Island, calling my attention to the prevalence of typhoid fever there. and that they wished some examinations made of the supply. He brought over some samples to my laboratory, and I found that the water was infected or was not suitable for use, being, in my judgment, a water polluted with sewage. This lead to my going down to Rock Island and as the result of a conference held by myself with Dr. Craig, who was the Health Officer for the city, and the Mayor, it was decided to institute a series of experiments to determine whether the supply were really polluted.

At that time there was a filter system installed which was inefficient and unsatisfactory and at the time I was there they were pumping raw Mississippi river water into the mains. Upon investigation I found that the intake from the public supply of the city of Rock Island extended out from a second well, not the main pumping well, but a smaller second well, into the channel of the Mississippi river under the so-called "slough," formerly a branch of the river which divided around Rock Island; at present it is not in the true current of the river, but forms a tail race for the water power at Moline. This slough receives the sewage from Moline and also a considerable portion of that from Rock Island.

10928 I found upon investigation that one of the main sewers from the city of Rock Island, which comes down, I think it is 21st street, empties a few hundred feet, about 400, above the intake pipe, and the sewage from that sewer therefore would naturally pass down over the pipe. It, therefore, seemed to me reasonable that if there were leaks in this intake pipe, or if there were leaks in the rip rap wall which formed the abutment about the well, that this sewage would find its way from the sewer directly into the mains. A series of experiments were inaugurated, taking advantage of the chlorine content of the water, by which we endeavored to see whether that rip rap wall on the intake pipe itself was intact. The experiment consisted in putting in a considerable quantity of salt, along the rip rap wall, distributing it along by the workmen; knowing the chlorine content of the water, both of the slough and of the natural river water, we could, by taking analysis afterwards show whether there would be an increase in the amount of chlorine. The result of this experiment showed that the salt having been added to the water at about 3 in the afternoon, in the course of about two hours the amount of chlorine as salt in the water increased. It increased until evening and did not come back to the normal until late the following morning. This lead 10929 to an investigation of the well and upon the water in the well being lowered it was found that there was abundant leakage from the river through the wall into the well. In the report which was made to me it stated that there were as many as 200 small leaks.

It seemed to me very clear that this sewer was directly responsible for that epidemic and it was certainly true that the sewage from this sewer found its way into the supply. It is of more importance in this connection because upon that sewer was located a hospital which at that time was crowded with typhoid fever patients. I understood there were so many that there were not sufficient rooms and they were placed upon cots along the hall.

Further, in the course of investigation, we made a study of the bacterial content. There was abundant evidence of the colon forms in the water and to the best of my understanding of the problem I believe we isolated a germ of the genuine typhoid bacillus from there, from the water supply. The study of the form, however, was not carried out as far as since then, I wish it had been, but in the best of my own judgment and of my assistant, I believe that that was a typhoid bacillus. We did not apply the Widal reaction to it for we did not have any typhoid fever patients in Beloit. It responded to all the characteristic

10930 typhoid group except that one. We did not have the material to apply any further investigations, and hence they were stopped. I was informed by Dr. Craig, the Health Officer of Rock Island—that at this time about five per cent. of the school children of the town were down with typhoid fever. Those are the essential details, as I recall them after three years.

In the other cases to which I referred, there was typhoid fever in the towns and I had to do with the study of the supply, but I would not lay it wholly to the supply. As for West Superior there was a large use of well water and superficial wells so the problem there is very much more difficult to definitely fix. There might be some question about it.

I could take up Menominee only in a general way. The supply at Menominee, which is right across the river from Marienette, is taken from Green Bay by an intake pipe extending out 2,000 feet. A short distance away (about ¾ of a mile) there is the outlet of a sewer which contains or receives a considerable portion of the sewage of the city. That water varies in quality and while you would expect true normal Green Bay water, that is, essentially Lake Michigan water, it varies at times,
10931 owing to the probable drift of the sewage, owing to the currents generated by the winds, etc. Typhoid fever is undoubtedly partly brought in by lumbermen from the pineries, but I think the water supply there contributes somewhat to it, although I have never found in the supply evidence of a large amount of sewage. I have acted for years as consulting chemsit of that company and from the samples analyzed we have occasionally found colon forms. Sometimes the fermenting forms are found.

There was an outbreak of typhoid fever in Ashland, I think two years ago, and I was called there by the city to investigate that problem for them. I found that the filters which were installed some years before, a system of slow sand filtration, had been improperly operated. The sand had not been renewed for some time and it had thinned down in the process of cleaning. The filters were cleaned in November and the water was very cold, and immediately following this cleaning the waters were unsatisfactory; that is, sewage from the bay undoubtedly found its way in through these filters, and I attributed the conditions then, on the outbreak of typhoid, to that condition of the filters.

After the new sand had been put in—at my order or
10932 suggestion, and the sand increased up to its proper thickness, about 36 inches, after allowing a proper time of the "seeding of the bed," as we say, the bacterial content of the waters came down so that from that time to this, and I have made monthly examinations of that water for the last two years, I have never found a sewage form in the water, until last week from other causes. The typhoid fever epidemic died down and since that time there has been no typhoid in Ashland attributable to the water supply. They have some cases, but they are brought in. The Health Officer informs me there has been none since then.

I was called to Ashland before the filter plant was installed and at that time there were about 400 cases, and I was asked to investigate the condition of the supply. At that time they were pumping raw water into the mains. I was called there when they were pumping raw unfiltered bay water, and there was a serious typhoid epidemic, I think about 400 cases, at that time in the city. At my recommendation the company was asked to change the supply and abandoned the bay supply and adopted a system of artesian wells. This supply was found, upon testing, to be inadequate in quantity, and that lead to the installation of
10933 a system of filters, the slow sand system, and up to this outbreak, which was in 1902, typhoid fever was practically stamped out of the city and only reappeared when the filters had been improperly operated; that is, the sand bed had been thinned down by repeated cleanings, so that at points it was not over eighteen inches in thickness, and if I recall rightly at one point near one of the pillars it was down as low as 12 inches.

In this condition the bed was cleaned in November, in the cold weather; the water was then put through, and immediately after, alowing for the proper period for incubation of the disease, the epidemic of typhoid fever broke out. At my order, that sand bed, after the investigations of the conditions, was thickened back to 36 inches, and filled with properly prepared sand, and since that time, I am informed by the Health Officers, there has been no typhoid fever in the city.

As a matter of fact there was another condition of the bed which was related to me by a friend, an engineer, who went there at the time, and he went down in the well before I went there

and he found that the bed had become clogged, so that the filtration was not sufficiently rapid; on looking down on the
10934 filter bed he observed ridges as though the man operating the bed had been down, and with a rake had broken up this crust, and by so doing let the waters through. That was a thoroughly inefficient operation of the plant. He thus broke the "schmutzdecke," the protection coating, up. He broke that up, because the process of filtration had become clogged so that the water could not get through. That is as I was informed, soon afterwards by one of my friends. Certainly the filter bed had been thinned down to where the filter was imperfect; that was determined by means of bacteriological analysis made by ourselves in the laboratory at home.

Q. Have you had anything to do with the processes of filtration in your sanitary work?

A. In the prosecution of my sanitary work I have had a great deal to do with different systems of filtraton. In fact, I have done work upon filter systems of one sort or another at Davenport, to which water company I have acted as consulting chemist for ten or twelve years, with the filter plant at Rock Island, with the filter plant at Ashland, at Independence, Kansas; at Burlington, Kansas; at Cedar Rapids, Iowa; at
10935 Beaver Falls, Pennsylvania; at Warren, Ohio; at Brooklyn, N. Y.; Binghampton, N. Y.; Denver, Colorado; Kankakee, Ill., Eau Claire, Wis.; Oshkosh, Wisconsin; West Superior, Wis.; Burlington, Iowa.

Q. Describe briefly what connection you had with this filter business?

A. I have been acting under the name of "consulting chemist" to either the company operating the plant or the city.

Q. What were your duties?

A. My duties were to look after the quality of the water, the conditions of the filters and determine the efficiency of filtration, meaning by that the satisfactory character or otherwise, in which they were doing their work.

Q. Are you acquainted with the different kind of filters?

A. I think I have worked practically with every make of the so-called mechanical filters which are made in this country. I have also done work upon the so-called English system. I have once been abroad for the purpose of investigating foreign systems of filtration. I have also been called upon three or four times to recommend types, and in consulting capacity regarding the form of filter to be introduced.

Q. Mention those places?

10936 A. I have been consulted upon the system of filtration introduced at Burlington, Iowa; the system at New Brighton, Pa.; at Ashland. The whole matter of filtration at Menomenee has been up under advisement. The readjustment of the plant at Cedar Rapids. Working over the plant at Oshkosh, Wisconsin, where they had an alarming outbreak of typhoid fever a few years ago. I also made a report upon the proposition of establishing a filter plant for the city of Minneapolis, Minnesota, and elsewhere.

Q. What filter systems in Europe did you investigate?

A. The systems of filtration at London, Paris, Antwerp, Berlin and Hamburg.

Q. What are the characters of those European filters in a general way?

A. The so-called sand filters. They are essentially large basins, excavated, rendered water tight by cement construction, and then filled with the sand to an appropriate depth; this sand being suitably prepared and screened, the whole being supplied with a system of underdrains for receiving the purified water and the necessary apparatus for supplying the raw water.

Q. Briefly, what are the characteristics of filters employed in the places that you have detailed? 10937

A. The system of slow sand filtration is in use at Ashland; at other places the American system is in use which consists in adding a chemical to the raw waters as supplied to the bed; by so doing getting greater speed of filtration, and with efficiency if properly conducted, which is strictly comparable with the best results.

Q. What chemicals?

A. Generally alum or sulphate of alumina; more recently iron in some form, with the addition of lime to assist it.

Q. Are you acquainted with the literature bearing upon the typhoid fever epidemics of this country?

A. I have studied it carefully I think.

Q. Are you acquainted, from the literature, with the epidemics at Plymouth and Lowell?

A. I have read of them several times.

Q. Are you acquainted with any epidemics other than typhoid fever?

A. I have never made any studies of any other epidemics. I have read of them in a general way, but have had no personal study of them.

10938 Q. Have you made a special study of water analysis?

A. I have devoted practically all of my available time to that since 1885.

Q. What branch of sanitary science have you given special attention to?

A. The study of water supplies, their purification when necessary and the adaptability to public use.

Q. Have you had any experience in the interpretation of chemical and bacterial analysis of water?

A. That study includes especially the study of the interpretation of the analyses and their significance from a sanitary standpoint.

Q. In your work as a sanitarian have you done any work in the chemical and bacterial analysis of water?

A. Yes, sir; I have installed at Beloit a private laboratory which is given up practically wholly to the study, and is known as the Beloit Sanitary Laboratory, and I have kept an assistant for some years, working all the time practically upon problems of this kind; in the course of this work we have made about ten thousand analyses of waters. Under my direction another laboratory was established in 1896 or 1897, at Denver, Colorado, where we made in three years about six thousand an-
10939 alyses. These were mostly bacteriological analyses.

Q. Have you examined and studied the chemical and bacterial analysis of the water of Lake Michigan, the Drainage Canal, the Desplaines, the Illinois, the Mississippi and Missouri rivers, as made by Professors Jordan, Gehrmann, Palmer and Burrill, the same being published in what is known as Reports of Streams Examinations, published by the sanitary district of Chicago?

A. I have read them carefully.

Q. Are you acquainted with the Chicago river, the Drainage Canal, the Desplaines, the Illinois and the Mississippi rivers from Grafton to St. Louis?

A. Yes, sir; I know the Chicago river, the Drainage Canal, the Desplaines, the Illinois, the Mississippi from Grafton to St. Louis.

Q. What opportunities have you had for becoming acquainted with the water course from Chicago to St. Louis?

A. Among others was a trip made down the river from the mouth of the Chicago river, in Chicago, during the month of September last, in company with some other gentlemen. The excursion started at the Graham & Morton Docks at Chicago, thence down the Chicago river, out through the canal, 10940 and as far as the bear trap dam, when we went around the river at that point, it not being navigable. From Lockport to Joliet we went on the electric cars, thence on steam car, by the Rock Island road, to Peru, where a boat was taken and then by boat to the mouth of the Illinois river, and thence on the Mississippi river down as far as the Eads bridge at St. Louis.

Q. Was this trip made in the day time?

A. It was made wholly in the day time, that is on successive days.

Q. Have you made a special study of bacteriology?

A. As indicated in my qualification.

Q. What are bacteria?

A. Bacteria are low forms of life, microscopic in character, being one of the lowest forms of vegetable life.

Q. How are they classified and distinguished?

A. There are different systems of classification. I generally think of them as being either saprophytic or parasitic or classified either as pathogenic or non-pathogenic.

Q. How are they distributed?

A. They are distributed widely in nature, being in the soil and in the air, in waters and in animals, and vegetables.

10941 Q. What are the characteristics of bacteria peculiar to water?

A. It is rather a difficult question to answer, but as we ordinarily think of water bacteria they grow generally in a nutrient or gelatine media, quite luxuriantly, at ordinary room temperature, developing colonies that tend to liquefy the gelatine and are not very easily differentiated. Water bacteria are not inclined to grow at elevated temperature or the temperature of the body. We rarely find very many water bacteria growing at the temperature of the living body, 37 degrees centigrade. They have a tendency to grow at about 20 degrees or thereabout.

Q. Please distinguish between the so-called saprophytic and parasitic?

A. The saprophytic are those that live on dead matter; the parasitic those that live upon living matter.

Q. Distinguish between the pathogenic and non-pathogenic?

A. Pathogenic bacteria, I understand, are those which may produce harmful and even fatal effects upon human beings; non-pathogenic those which do not.

Q. What are the known pathogenic bacteria to man?

A. I can not give all, but some of the common ones are those characteristic of typhoid fever, scarlet fever and cholera, of tetanus or lockjaw, and erysipelas. Those are among
10942 the more common ones.

Q. What kind of pathogenic bacteria have you given particular attention to?

A. Especially the typhoid form.

Q. What pathogenic bacteria are water borne, taken that way into the human body by means of drinking water?

A. The two to which most attention has been given are the typhoid germ and the bacillus of cholera. Those are the two important ones. There are others which may produce diarrhoeal diseases.

Q. What is the bacillus prodigiosus?

A. It is a form of organism which is not commonly known as we do not think of it as being widely distributed in nature. It has certain characteristic properties and growth. It does occasionally occur. It was found originally in the south of France, and is especially noteworthy for the peculiar appearance it represents in the growth upon gelatine medium in ordinary temperatures.

Q. Is it found in river waters?

10943 A. I understand it has been occasionally found in river
waters. There are cases where it has been found in the river waters. Franklin speaks of finding it, and he mentions another case where it has been found.

Q. Have you found it?

A. I am not sure whether I have or not. I found a form at Menominee which suggested it. It was very closely allied to it. There was no attempt made to differentiate it and determine whether it was or not.

Q. Are you acquainted with the experiments made with the bacillus prodigiosus by Dr. Ravold?

A. I have read of it.

Q. Assume that 107 barrels of 40 gallons each of culture of bacillus prodigiosus, consisting of one thousand million bacillus to a cubic centimeter as contained in said barrels, was deposited in the Chicago Drainage canal at the town of Lemont on the afternoon and evening of the 6th day of November, 1901, during the period from four to eight hours.

10944 Assume further that immediately after the said barrels were emptied into the drainage canal the laboratories established, at Lockport, Joliet, Peoria, Grafton on the Illinois river and the intake tower of the St. Louis waterworks, chain of rocks, were notified, and that samples were collected at each of these places every hour of the day and night for the purpose of bacteriological analysis, for the ascertainment of this bacillus prodigiosus, and,

Assuming that at Lockport these hourly samples taken day and night were taken from November 7th to November 25th, a period of 18 days, the total number of samples taken being 432;

Assuming that at Joliet these hourly samples taken day and night were taken from November 7th to November 25th, a period of 18 days the total of said samples being 432;

Assume that at Peoria these hourly samples taken day and night from November 8th to November 30, a period of 22 days, amounted to a total of 528;

Assume that at Grafton these hourly samples were taken day and night from November 12th to December 15th, a period of 33 days, the total number amounting to 792, of which 384 were analyzed by Dr. Ravold;

10945 Assume that the total number of samples taken hourly day and night at the chain of rocks was 720;

Assume that at the laboratory tap these hourly samples taken day and night from November 20th until March 1st, 1902, a period of 100 days, amounted to a total of 2400;

Assume that the total number of samples analyzed at the different points above mentioned was 5304;

Assume, further, that on December 4th at 8:45 a. m., 1 bacterium prodigiosus was found at the intake tower, chain of rocks;

Assume that on December 5th at 9:00 a. m. 1 bacillus prodigiosus was found at the intake tower, chain of rocks;

Assume that on December 8th at midnight 1 bacillus prodigiosus was found at the intake tower, chain of rocks;

Assume that on December 6th at 8:00 a. m., at Grafton, 1 bacillus prodigiosus was found,

And assume, further, that these five organisms were all the organisms of prodigiosus that were found in the examinations made from Lockport to the intake tower at the chain of rocks and the laboratory tap in the City of St. Louis, which were made during the progress of this investigation as hereinbefore set forth; and at no time was there more than 1 single
10946 bacterium found at each of these places.

Assuming all of the facts as hereinbefore stated to be true, what is your opinion as to the value of this experiment as indicating the probable longevity of the typhoid bacillus as measured by the longevity of the bacillus prodigiosus, and the probability that a typhoid bacillus entering the drainage canal from the sewers of Chicago will ultimately find its way through the Desplaines and the Illinois river, surviving the journey down the Illinois and Mississippi rivers to the intake tower at the chain of rocks at the City of St. Louis?

A. Why, in my opinion that does not possess value as touching the probable longevity of the typhoid bacillus. The longevity of the bacillus prodigiosus is not necessarily a measure of the longevity of the typhoid bacillus, and it does not contribute to the probability that a typhoid bacillus, entering the drainage canal, etc., would find its way through. But on the contrary, it seems to be an improbability that it would.

10947 Q. What reasons have you for that opinion?

A. Well, in the first place the bacillus prodigiosus is known to flourish under ordinary temperature, given the proper food stuff, and I do not know of any evidence contributory to the knowledge that the typhoid fever organism flourishes and develops in water.

As to the probability that a typhoid bacillus would pass down the canal it seems to me that the experiment first of all does not show that these bacilli were those which were placed in the water, as we have evidence that they are occasionally found, or forms resembling them are found, in our natural waters. Further, upon studying the question it seems to me that if the bacillus prodigiosus had remained in the water for any length of time they would have found them far up the river, but as I understand the results they were not found above Grafton. If they should persist in constantly diminishing numbers it seems to me reasonable to assume that if these organism
10948 were those which actually found their way down the river they would have found them in increasing numbers in the samples taken above; but they did not find them until they reached Grafton, although as I understand from this question numbers of samples were taken, e. g., as 432 samples taken at Joliet. But there is no record they were found there.

Q. Assuming the conditions of this question, they are not found up stream only in 5 cases at the lower part of the course, what importance do you attach to the experiment as assumed in the hypothetical question?

A. Well, as they are operative in that way, it seems to me to be a contribution to the study of the self-purification of that stream. It is an evidence for the stream being rid from them rather than anything else.

Q. Have you made any special study of the typhoid germ in connection with your sanitary work?

A. Yes, sir; I have made such a special study of that organism.

Q. Where are typhoid germs found?

A. Typhoid germs are normally found in the intestinal tract of man and distributed through the body of those suffering with typhoid fever, especially in the spleen, and at other
10949 points in the body as at the abdomen, localized there. They are found in the feces and in the urine discharged from patients suffering from typhoid fever.

Q. What germs do they resemble?

A. The typhoid germ especially resembles the colon bacillus which is the normal and constant inhabitant of the intestinal tract.

Q. What methods can be employed for determining and identifying the typhoid bacillus?

A. It would be a very difficult thing to determine the presence by the methods which have been usually employed for the detection of typhoid bacillus in water. There have been some methods developed very recently, these require special media which I have never used. The typhoid bacillus is very difficult to determine in an unknown water. If I were asked to determine the presence of them I should make the cultures on agar at elevated temperatures and then transfer these growths to other media as the growth on gelatine, the growth in
10950 lactus broth and then apply the so-called Widal reaction for the detection of it.

Q. What significance is attached to the presence of the colon bacillus when found in water?

A. The presence of the colon bacillus in water is very significant, because the colon bacillus is the constant inhabitant of the intestinal tract of man and most of the domestic animals. Now, it is not present, certainly in any numbers, in a natural unpolluted water.

I believe there is a question whether some of the fish do not excrete them in very small numbers, and therefore we do occasionally find the colon bacillus in an unpolluted water. As the colon bacillus is the normal inhabitant of man, if we find the colon bacillus in any amount or quantity or number in a water, it is a presumptive test that fecal matter as such finds its way in that water.

Q. Is a colon test one that is used by sanitarians largely in ascertaining the quality of water?

A. It is one of the most important tests used in the determination of the sanitary quality of a water supply.

Q. What is the probable longevity of typhoid bacillus in the human body?

10951 A. It is present in the body in large numbers at the time of disease and will remain for some months, six months or so, at least, after a person has recovered from typhoid fever. It will then be found in the urine and in the discharges from such persons.

Q. Have you any knowledge of its longevity in soil?

A. Only by reading, not by direct experimentation. Such readings show that certain germs have been found in soil after months, sometimes as high as six months.

Q. What is the longevity of typhoid bacillus in water?

A. That has been the result of a good deal of experimentation, and different observers have set different periods of duration of life of the typhoid bacillus, in water. Mr. Frankland, in his Micro-organisms in Water records a case where it was observed after 100 days in sterilized natural water and this may be taken as the maximum which I have seen recorded in any experiments.

Q. How in unsterilized water?

A. It would tend to diminsh in numbers and disappear after
a few days, some records putting it as six or seven days,
10952 and some as high as 26 days, which is the highest I have
seen recorded, but that would depend upon the quality
of the water used.

Q. Does the typhoid bacillus multiply and increase in nature?

A. No, I understand it does not.

Q. Are conditions of the laboratory experiments more or less favorable than conditions in nature for the longevity of the typhoid bacillus?

A. They are rather more favorable for the longevity than those we meet with in nature.

Q. For what reasons, Professor?

A. I believe one of the reasons given for that is that the glass itself seems to affect the water. Then there are other conditions, the uniformity of temperature, the fact that they are under exactly the same conditions all the time, being different from those than an organism would meet with in a running stream. The change of temperature and change of conditions, owing to change of temperature and the type of water that it comes in contact with, the other micro-organisms which they
meet in the running stream they would not meet with
10953 when they are by themselves in the jar in the laboratory.

Q. Will the germ of typhoid fever live as long in polluted water as in pure sterilized water?

A. Experiments shows they will not live as long in polluted water as in sterilized water. In fact the longest period of life which we have observed in the case of the typhoid bacillus in experimental work is where they have taken natural water and sterilized it.

Q. How do you account for this?

A. The organism in a polluted water is subject to certain enemies. It is subject to the toxins thrown off by the other forms and to the concentration of the toxins and to the varying conditions of the stream. If an organism be placed in polluted water, it will be subject especially to the destructive action of the type of the other organisms more than it is in a natural drinking water.

Q. Are you familiar with the experiment that was conducted by Professors Jordan and Zeit and Russell upon the longevity of the typhoid in Lake Michigan, Chicago River, 10954 the Drainage Canal and the Illinois River?

A. I have read the experiments, especially as conducted by Professor Jordan; also the others, but his more minutely.

Q. Were you present at the time that this experiment was first suggested?

A. I think I suggested it myself first, at the time of the conference. I am quite sure that I first suggested carrying it out and insisted upon it being done as a very important factor to determine the duration in life and the conditions met with in life.

Q. That was on the trip down the river?

A. I think it was brought up the second day after we passed Peoria.

Q. From your knowledge of the quality of the water in the drainage canal, the Desplaines and the Illinois River, and from your knowledge of the experiment that was made or carried out and the results of the experiment, what is your opinion as to the longevity of the typhoid bacillus in those waters?

10955 A. From such a study as I have been able to make of the quality of the waters in the canal and the Desplaines and the Illinois Rivers, and from the study, especially of the work of Prof. Jordan, it is my opinion that the viability or duration of life of the typhoid bacillus must be brief, surviving but two or three days, so far as those experiments show, not extending beyond that. It was recorded in the experiment, that isolated cases were found as late as the ninth day, but out of some

1100 tests, if I recall just right, by Professor Jordan, in only three of those was he able to note the presence of them. All of them were on a single plate, and the same day. It seems that that experiment would tend to show that the duration of life of the typhoid bacillus in the Illinois River must be brief, not more than three days, or so.

Q. How do you account for your assumption that the life of the typhoid in the water of the Illinois River is shorter than as compared with laboratory experiments?

A. I believe it to be largely due to the toxic effect of other organisms upon them. What contributes largely to their disappearance is that their enemies produce these results
10956 by the elimination of these toxins. I believe that to be the prime factor in that experiment.

Q. Are you acquainted with the physical conditions of the drainage canal, the Desplaines River and the Illinois River and the Mississippi River from Chicago to St. Louis?

A. Yes sir, I have been over the ground and have made a study of the surroundings such as could be observed from making this excursion alluded to.

Q. You are acquainted with the dams that are found in the Illinois River?

A. Yes sir, as they were seen that trip.

Q. What effect in your opinion do these dams have upon the problem of sedimentation?

A. These dams are five in number in the river, and they would naturally increase the amount of sedimentation of the river because the dam would check the flow of the water and in the checking of the flow suspended matters would tend to be precipitated. The waters are brought to a more quiescent
10957 condition and as a result matters in suspension go down.

Q. How is sedimentation, in your opinion, in the Illinois River affected by high and low stages of water?

A. Well, a high water always tends to increase the amount of sediment contained in water, but in the Illinois River we meet with physical surroundings which tend to compensate for this increasing of sediment so that in the high water of the river you will have a heavy sedimentation from overflowing and carrying the water out over the low lands.

Q. Will bacteria respond to the law of gravity in pure water of a running stream?

A. Yes sir, they will respond to the law of gravity in the pure water of a running stream, but slowly. The tendency of the bacteria is downward, even in a running stream, but with moderate speed. Of course if you should take a water like that in the South Platte, which I had occasion to study very carefully, there is no sedimentation. The Platte River dashes down the mountain from the South Park, and it is rushed over
10958 those rocks and there is nothing like sedimentation in
that stream. There is no opportunity given for sediment to settle so that we find these bacterial forms down the stream in that river. The sedimentation does not begin until you strike the low lands at the foot of the mountains. This is an extreme case, but if you should have a quiet running stream moving along slowly, you will observe some sedimentation of bacteria and if the water became quiet the bacteria will gradually settle to the bottom in a short time. You may have all grades of deposit between those two experiments so that in my opinion, in a stream running slowly there would be some deposit even in a clear water.

Q. When there is sediment or matters in suspension in a running stream does that assist sedimentation of bacteria?

A. Greatly.

Q. In what way?

A. The bacteria tend to fasten upon these particles of suspended matter and they being much heavier gravity than the water are carried down with the sediment. The sed-
10959 imentation of waters when brought to a quiet condition
differs with different streams. Now, bacteria put into settling basins at Omaha, for instance, are deposited from the water if it be brought to a quiet. You may have an action of silt itself upon the bacteria which, in my judgment, will be not alone, as fastening on of the bacteria, but there will be an action like that of alum in cases of sedimentation, so that a sediment has a tendency to fix or as we say precipitate and carry down these matters. I believe that to be true in our western streams as I have studied them, and if therefore a stream should carry a silt of a hydrous character you will have a direct action of the silt upon the bacteria suspended in the waters. Thus you have

all these elements at work in the case of a sediment in a stream assisting in that purification and tending to throw the bacteria down.

Q. Could a sufficient amount of water from Lake Michigan be carried through the drainage canal into the Desplaines and Illinois rivers, so as to create a condition of clearness in the combined waters of Lake Michigan and the Illinois River so as to preclude the opportunity of sedimentation in the Illinois River, assuming that the maximum amount that could be 10960 carried through the drainage canal was 800,000 cubic feet per minute?

A. In my opinion that amount of water passing into the drainage canal could not produce a condition of clearness to preclude the possibility of the opportunity of sedimentation.

Q. From the Illinois River as you had occasion to observe it, what is your opinion whether if such an amount of water should be carried into the river there would have been a large amount of matter in suspension in the waters of the Illinois River below LaSalle?

A. In my opinion there would be a considerable amount of sediment yet remaining in the waters.

Q. Assuming that the entire sewage from the city of Chicago should be diverted into the drainage canal and that 800,000 cubic feet of water per minute from Lake Michigan should pass over the Bear Trap Dam would that amount of dilution be sufficient after it reached the Illinois River, mingled with the sewage of Chicago to so separate the matter in suspension in the Desplaines and Illinois Rivers as to prevent the opportunity of sedimentation of bacteria?

A. For the reasons given before it is my opinion it would not.

Adjourned until 2 P. M. same day.

10961 2:00 P. M., Friday, February 26, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

PROF. E. G. SMITH,

resumed the stand for further direct examination by Mr. Todd and testified as follows:

Q. What sanitary significance does dilution have in considering the problem of self purification of streams?

A. The dilution of a water with the water of a better quality is one of the well recognized factors in the problem of self purification of streams.

Q. Manifesting itself in what way, Professor?

A. Manifesting itself in the dilution of a water with the water of a superior quality. It manifests itself in separating objectionable micro organisms and thus diminishing the liability of the same being taken into animal economy.

Q. Is the danger of infection really diminished by dilution?

A. A sewage laden water diluted with the water of a better
10962 quality is thereby rendered less liable to communicate
disease by infection.

Q. Is it a fact that the greater the dilution of sewage the less the danger from infection?

A. It is generally accepted by sanitarians that the dilution of sewage diminishes the danger from infection, the greater the dilution the more the micro organisms are separated and the less the liability of the same being taken in by man.

Q. What effect in your opinion does the dilution of the Chicago sewage with the purer water of Lake Michigan have upon the conditions of the water in the Illinois River?

A. In my opinion the addition of the purer water from Lake Michigan to the sewage improves the quality, that is diminishes the danger from the sewage in that the micro organisms are more separated from each other and also because it gives the river greater area for facilitating the sedimentation of solid matters suspended in the same.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition
of the Illinois River considered from the standpoint of
10963 dilution alone?

A. It decidedly improves the sanitary condition of the Illinois River, simply on the ground of that dilution for the reasons given that it separates the organisms and thus one receiving the water becomes less liable to infection.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois River considered from the standpoint of a chemical and bacterial change taking place?

A. In my opinion Lake Michigan water added to the sewage of Chicago is decidedly beneficial to the sanitary condition of the river from the standpoint of the chemical and bacterial changes taking place because so far as the chemical changes are concerned, and the bacterial changes also, there will be an elimination owing to the processes of sedimentation of material carried by the water and therefore the quality of the water would be improved.

Q. If a sufficient volume of Lake Michigan water would be added to the sewage of Chicago as to cause the elevation of the water in the Desplaines and Illinois River what effect would this increased volume of water have upon the question of sedimentation in the Illinois River?

10964 A. It seems to me evident that the raising of the Illinois River level would make an increased volume of the river which would widen the sedimentation area and that this sedimentation of the river would be decidedly increased by this rise of level, and thus the total sedimentation of the river would be greatly increased; and further, this raising of the level would also increase the total volume carried by the river so that relatively there would be a smaller quantity of the sediment in any given volume of the river. Thus, it works both ways, hastening the processes of sedimentation.

Q. How does the physical condition of the Illinois River compare with the other rivers of the country for the purpose of purification and sedimentation?

A. It is my opinion that the physical conditions of the Illinois River are such as to be well adapted to sedimentation as compared with other rivers with which I am acquainted.

In support of this it seems to me that the low shelving banks of the river are such that a slight increase in

10965 the volume of the river and thus a raising of the water above its level tends to broaden out the depositing area for the sediment. For instance, as compared with the Platte River in Colorado which I have studied very carefully, there is no opportunity for sedimentation at all owing to the precipitous sides of the stream. The main bed of the river rushes down between sides practically vertical and rocky, with no opportunity for spreading out and sedimentation. Now, that is far from the conditions in the Illinois River. Here you have the low shelving banks and the sedimentation area of the river therefore is increased.

Along the Mississippi River as I have studied it and had opportunity to see it and study the sanitary quality of its waters in my judgment you do not meet with the same conditions you have here owing to the high bluffs running right down to the river, preventing any spreading out of this river as would obtain if there were low banks bordering its sides and therefore its sedimentation area can not be greatly increased. Now, as compared with the Rock River in Wisconsin with which I am also familiar; there the banks are not low and do not
10966 admit of this sedimentation. There the banks are more precipitous and the river does not have that tendency to widen out. Take many of the rivers up through Wisconsin, for instance the Menominee River does not have these low banks but it tends to be held within its banks and thus dilution would not materially increase the area of deposition for sediment.

The general principle, it seems to me, is that the low lands along either side of the river are quite marked on the Illinois river as compared with others that I have followed along. Cedar River in Iowa would be another that has not this characteristic.

Q. From your knowledge of the physical conditions that obtain along the Illinois River as well as your knowledge based upon the study of the results of the analysis as they appear in Streams Examinations on the water both chemical and bacterial of the Illinois River, what effect, if any, does the sewage from Chicago discharged into the drainage canal have upon the waters of the Mississippi as the same passes along the shore of the State of Missouri?

10967 A. In my opinion all the conditions affect the quality of the Illinois River. Its physical surroundings; the study of the chemical analyses, the comparison of the bacterial analyses; the death rate of the typhoid bacillus; the rate of flow of the river, the Illinois River as discharged into the waters of the Mississippi does not affect its quality as it passes along the State of Missouri, in fact the data probably indicate that the

Mississippi River is not of as good quality as the Illinois River itself in its lower reaches.

Q. What is your opinion as to whether any pollution dangerous to public health entering the drainage canal from the sewers of Chicago reaches as far down the Illinois River as the town of Grafton?

A. In my opinion it seems to me quite clear that there is no pollution dangerous to public health from the drainage canal which received the outfall from the sewers of Chicago which reaches down the Illinois River as far as Grafton.

Q. What evidence have you that will justify the conclusion just expressed?

A. There are several factors in connection with the river and the study of the agencies at work in the self purification of the stream in my opinion would justify that statement.
10968 We have the agencies of dilution of the sewage whereby the sedimentation of the river is augmented for the reasons previously outlined.

We have the experimental work showing the short life probably not exceeding three days of the typhoid bacillus in the waters of the river.

We have the rate of flow of the river showing that the time required for substances to pass from the drainage canal at Chicago to Grafton considerably exceeded the life period of these organisms as revealed by the special experiments upon the typhoid bacillus of this particular river.

We have further the study of the river from a chemical standpoint which shows the purification of the river from that standpoint and we have also the data from the bacteriological investigations all a matter of evidence which show that the waters have purified themselves from the bacterial standpoint. That is, the waters of the Illinois River at Grafton appear from the chemical and bacteriological standpoints as evidenced by these data to be of the quality of other rivers of this sec-
10969 tion.

To sum up these conclusions, in my opinion, the several agencies at work make the Illinois River at Grafton about a normal river water in this section.

Q. When you referred to chemical and bacterial data from what source did you get that data?

A. I understand wherever that word is used, from the chemical and bacterial data, it is from this report of the Streams Examination. It is understood that my conclusions must be based upon these data as I have not done experimental work myself.

Q. What is your opinion as to whether any infectious matters coming from the sewers of Chicago by way of the Drainage Canal, in a dangerous state, reach as far down the Illinois River as Grafton?

A. It is my opinion that infectious matters coming from the sewers of Chicago by way of the drainage canal do not reach as far down the River as Grafton for the reasons I have outlined in my answer previously given.

Q. Would the condition of low water in the Missouri River at a time when there was high water in the Illinois River be in any way a factor in carrying infected and polluted matters from the sewers of Chicago to the city of St. Louis?

A. It is my opinion that it would not enter in as a factor
10970 because in my opinion the waters of the Illinois River
have become purified through the process of self purification and removed the infected and polluted matters and therefore the condition of the Missouri River does not enter into the discussion.

Q. Professor Sedgwick, in answer to this question on page 3545 of the record: "Professor, will you state whether or not it is within the bounds of human possibility for any competent expert to say that in the period of low water on the Missouri River, such as is likely to occur at next Christmas time, a thaw on the Illinois River shed, might not endanger the lives of the people using the water of the Mississippi shore and at the city of St. Louis by sending to them in that water the suspended sewage of the sanitary district of Chicago?" answered "I do not believe that it is, because in my opinion no competent expert either can or will say that any means exist at present by which such purified sewage can be warded off from the people on the Missouri shore and the citizens of St. Louis under these conditions." I will ask you to state what is your knowledge in regard to the assumption that low water might exist

in the Missouri at a time of flood water in the Illinois and
10971 also state whether you know of any means existing in the
Illinois River that would permit unpurified sewage from the city of Chicago to become a danger and a menace to the public health of the citizens of Missouri and the citizens of St. Louis?

Mr. Jeffries: I now move to strike out that part of the question which refers to Professor Sedgwick and what Professor Sedgwick said in answer thereto for the reason that it constitutes no part of the question intended to be propounded to this witness and is incompetent, irrelevant and immaterial.

A. I will answer the first part of that question by saying for reasons given that low water in the Missouri River would not affect the Illinois River and in answering the second part of it would say that I know of no means at present which would permit of this sewage passing. From my point of view the sewage is purified. The agencies of the river tending towards self purification have been at work and have transformed that sewage into harmless forms, so that the impure sewage from the
city of Chicago can not become a danger and a menace to
10972 the public health of the citizens of Missouri and the cit-
izens of St. Louis.

Q. Professor from your knowledge of all the conditions that obtain along the Illinois River as well as your knowledge of the conditions that obtain in Chicago and the drainage canal, also your knowledge of the water supply at St. Louis such as is had from the intake tower at the chain of rocks what effect does the sewage from Chicago have upon the water supply of the city of St. Louis or upon the waters of the Mississippi River as it passes along the state of Missouri?

A. For the reasons given above, the agencies which are at work in the Illinois River tending to the self purification of the stream and the removal of sewage material as such from the river it is my opinion that the sewage from Chicago does not affect the water supply of the city of St. Louis or the waters of the Mississippi River as they pass along the state of Missouri.

Q. What in your opinion would be the fate of a typhoid bacillus passing from the sewers of Chicago into the Chicago River and thence into the drainage canal and down the Desplaines and Illinois Rivers.

10973 A. From the experiments all a matter of evidence it is my opinion that the typhoid bacilli passing from the sewers of Chicago into the Chicago River, thence into the drainage canal are destroyed in a short period, not exceeding more than 3 or 4 days after passage into the Desplaines and Illinois Rivers.

Q. From a scientific standpoint what value do you attach to the experiment made by Professor Jordan and others as showing the longevity of the typhoid bacillus in polluted waters?

A. From a scientific standpoint the experiment of Professor Jordan has great value. It seems to show very clearly that the Illinois River being a polluted water, the typhoid bacillus will not exist in that water for more than three or four days. And this being a polluted water it has a direct bearing upon the general proposition that the typhoid bacilli are short lived in a water thus polluted.

Q. Does the experiment shed any light upon the longevity of a typhoid bacillus in the sediment of polluted streams?

A. It sheds light upon the longevity of a bacillus in the sediment of polluted streams inferentially. The experiment as I understand it did not embrace the actual persistence and
10974 presence of that organism in the sediment itself, but in my opinion it is reasonable to assume that the sediment of the steam would be subjected to essentially the same agency as the water itself, and it is my opinion that the sediment of a stream polluted would not retain the bacilli for a period measurably longer than the polluted water itself.

Q. Is there any such thing as purification of soil?

A. I do not understand that question fully, but as I interpret that question soil tends to have organic material removed from it. The processes of nitrification of soil tend to remove the organic materials and bacteria contained in the soil.

Q. Why is it that the typhoid bacillus will not live as long in polluted water as in pure distilled water?

A. In pure distilled water the toxic effect of other bacteria would be entirely removed. In the case of polluted water the toxins from organisms inimical to the typhoid bacillus would be operative, and to that principal I attribute the short duration of life of a typhoid bacillus in a polluted water, shorter than in pure water.

Q. What is your opinion as to whether the typhoid bacillus
will live longer in the sediment of a polluted stream than
10975 it would in the water of the same stream?

A. In my opinion it would tend to live longer in the sediment than it would in the water itself for the reason that the conditions of change are not so much in the case of the sediment as it is in the case of the water itself. That is a matter of opinion, however.

Q. How much longer would it live in the sediment?

A. We have no evidence bearing upon that.

Q. In your opinion?

A. Well, it would be difficult to fix an exact datum, but of course a bacterium being deposited in the sediment of a stream would have the same agencies at work as the water itself, but probably to a lessor degree so that the absence of these destructive agencies would tend to prolong the life of an organism which went into the sediment of a stream. It would not be my opinion that the organism would live for any great period longer in the sediment than in the water above it.

Q. Will you differentiate between the conditions that obtain in the moist soil and in the sediment of a running stream?

A. Well, in a moist solid the organism is fixed, and new conditions are surrounding the organism. It is open to the air. It is subject to a thin superficial layer near the air. The air percolates through the soil. That condition does not obtain in the sediment of a stream. It is true that the sewage of the stream is the cause of the sediment, and it therefore follows that
whatever toxins of the water have access to the organ-
10976 isms in the sediment of the stream so that the conditions
are entirely separate, one being fixed and the other having the toxic effect of the excretions from other organisms, finding free access to them, and more than that it would be subject to variations in temperature. It might at least.

Q. Does the time that a typhoid bacillus will live in moist soil furnish any criterion for its longevity in the sediment of a running stream?

A. In my judgment conditions are so different that what is true of one should not be applied to the other.

Q. Are the two conditions comparable?

A. In my judgment or opinion they are not comparable.

Q. Would the fact that a typhoid bacillus lives several months in the moist soil justify the assumption that it would live for the same length of time in the sediment of a river?

A. For the reasons I have already stated it is my opinion
that the assumption that it would live for the same length
10977 of time in the sediment of a river as it would in moist
soil is untenable ground.

Q. Mr. Fuller, in his testimony on page 4219 of my transcript of record, in answer to the question: "Is not the length of time a typhoid bacillus will live in a sediment of a stream more a matter of assumption than a matter of demonstrated proof," said "I consider that it is a very clean cut demonstrated fact that typhoid fever germs may and do and have continued to live in the sediment of running waters." "Q. For what length of time? A. I should say for a month or more, possibly in cases for years. Q. Who has demonstrated that it has ever lived a year? A. I think that the conditions existing in a moist soil in many rural places of this country where typhoid fever prevailed from time to time is proof that typhoid fever germs in the presence of moisture can live for such a time. If that were not so then there would be an elimination of the typhoid fever absolutely through the rural districts of this and other countries." I want to ask you, Professor, whether you know of any demonstration that shows that typhoid fever germs may and do and have continued to live in the sediment of running streams for the period of a year?

A. In reply to that question I would say that I do not
10978 know of any demonstration of typhoid fever germs hav-
ing lived for a period of one year in the sediment of a
running stream.

Q. What is your own opinion as to whether a typhoid fever germ will live in the sediment of a running stream for a period of a year?

A. In my opinion the typhoid fever germ would not remain in the sediment of a running stream for that length of time. The agencies of removal would be at work on the destruction of the germ for the reasons stated.

Q. What is your opinion based upon all the knowledge that you possess as to whether the typhoid bacilli coming from the sewers of Chicago and entering the drainage canal could survive the journey from Chicago to St. Louis, a distance of 357 miles, and be a danger and a menace to the people of St. Louis using the water of the Mississippi for drinking and domestic purposes?

A. It is my opinion from all the knowledge that I possess from a study of the analytical data and the conditions surrounding the river that typhoid bacilli coming from the sewage of Chicago and entering the drainage canal could not traverse that distance and survive. This being true, they could 10979 not possibly be a danger and a menace to the inhabitants of the State of Missouri using the waters of the Mississippi for drinking and domestic purposes.

Q. Are the settling basins, or do the settling basins of St. Louis afford any protection to the citizens of St. Louis against infectious matters in the waters of the Mississippi at the intake tower?

A. The use of settling basins for a muddy stream is a well recognized method of treating muddy water, and these are merely an example of that type of construction for the protection of waters and from the experiments which I have made elsewhere on similar construction I am clearly of the opinion that the system does afford some protection to the citizens of St. Louis from polluted matters which may be in the waters of the Mississippi river at the intake tower.

Q. Are the settling basins any protection to the citizens of St. Louis against the sewage of Chicago?

A. The sewage of Chicago, in my judgment, being eliminated from the stream owing to the processes of self-purification before the Illinois river reaches Grafton, the matter 10980 of the settling basins at St. Louis does not enter into the problem of the purification or non-purification of the sewage of Chicago, it not reaching that point as undecomposed sewage.

Q. Where a settling basin holds a sufficient amount of water to supply a city for thirty days and as the water is taken out for domestic use raw water is immediately supplied from an open river and typhoid fever should prevail among the people using said water, what is your opinion as to whether such a condition justifies the assumption that because the basin holds a supply for a period of thirty days that a typhoid bacillus will live in that water for such a period?

A. The fact that a settling basin holds a sufficient amount of water to supply for a period of thirty days, with a constant inflow and outflow of the water as this question supposes, is no evidence that the typhoid bacillus will survive thirty days. It is a well known fact in the study of purification of waters by means of sedimentation that the water must be rendered perfectly quiescent. It must not receive inflow waters in order that the maximum amount of purification may take place.
Now, that being true it can not be assumed that the
10981 period of life of this organism is thirty days, simply because the basin holds that amount.

Q. What is the significance of the term epidemiology?

A. The term epidemiology means primarily the study of epidemics and the factors entering into that cover a wide range in sanitary science, including the proof of prevalence of disease, its distribution, causes leading thereto, the sanitary conditions surrounding the inhabitants of the city, the nature of the food supply, the causes of pollution to which it is subjected, the methods of guarding against pollution of the food supply and the removal of waste products from a community. It embraces a wide study of those as being prominent among the topics discussed.

Q. Have you examined the typhoid statistics of the Illinois, the Missouri and the Mississippi watersheds above St. Louis as compiled in the table I hand you, made up from the certificates of the board of health of the different cities lying on the three watersheds?

A. I have examined such table and studied it carefully.

Q. Does epidemiology in its scope embrace the proper
10982 study and interpretation of the mortality statistics of a given city?

A. The mortality statistics is one of the important factors in the study of epidemiology.

Q. In the matter of the interpretation of the statistics what method do you employ?

A. I have always used in the study of such mortality statistics the number per thousand or the number per hundred thousand.

Q. Why have you taken that method?

A. It forms an accurate, a specific method of determining the rate for any particular city and can be compared with those from any other city.

Q. How does the method that you have employed differ from what is known as the mortality percentage basis?

A. I have not acutally used the percentage mortality basis but have followed the usage of most sanitarians in using numbers, and it seems to give, upon the whole, more accurate results; the mortality percentage basis might be misleading in its conclusion because, for example, you may have a city of 100,000 people and one year there might be 500 deaths, year after
10983 year from typhoid fever, but the deaths in one year
from all causes might greatly exceed those of any other year, for all causes, so that upon the percentage basis you would have a shifting result, whereas if you used the number per 1,000, you would have a constant result and thus make the results which would be strictly comparable.

Q. Is the mortality percentage method regarded as the most accurate among sanitarians and students of vital statistics?

A. I have always used the other method. I cannot answer that question. The other method is the one I have most always seen used, and used myself, believing it to be the most accurate, and gives the most comparable results.

Q. What are the liabilities of pollution and infection of the river coming from the rural districts, the rural population?

A. The liability of pollution and infection of the river from the rural population is very decided. The relation of the rural population is one of the important questions to be considered always in making up our studies of the epidemics of typhoid fever in any given locality.

Q. Is infection from the rural population as common
10984 as from the urban, in causing epidemics?

A. It is a very common cause of epidemics, often epidemics of some of our largest cities have been traced to causes outside of the city, in the rural districts.

Q. Do you know of any important typhoid epidemics in which the infection has come from the rural population?

A. I can think of two or three such epidemics. That historical case of Plymouth, Pennsylvania, is a case in hand, and the very recent one at Butler, Pennsylvania, is another case in hand, the epidemic at Ithaca, New York, was another case in hand. The causes of the typhoid fever in these were chargeable to the rural population. One case I considered historical, whether you would call it an outbreak or not, at Middletown, Conn., students eating oysters from the oyster beds that had received sewage. The oysters were taken and distributed, and students eating such raw oysters came down with typhoid fever. I don't know whether that would be a case in hand or not. Then, in my own experience, I am sure that the conditions of the prevalence of typhoid, in Denver, is due to the conditions
10985 outside of the city, either up the Platte river, or up the
Bear creek canon. As an example of actual experience in studying out the conditions of the water supply at Denver, and source of pollution to which it was subjected, we had occasion to increase the supply along the Bear creek, so-called which is a small stream which debouches from the mountains, about 13 miles from Denver, thence is carried along in ditches and put into Marston Lake, and from there put into the city. Under my direction the Denver Union Water Company spent considerable sums in cleaning up that water shed, buying up farms, and buildings, cutting out the brush and the undergrowth, and especially at Evergreen, a town some twelve miles up the canon, where we found a case of typhoid; it was supposed that the place was thoroughly disinfected, but another case broke out in the same house the following year. In fact, a brother and sister came down, and they were both sick in the
10986 house at the same time with this disease. The house was
upon a little plot of green grass, on the bank of the stream. We went up and had an order executed to take these two patients out of the house, and then burn the house down; we bought the property and made a contract to burn the house down, and cleaned out the place, liming it all down thoroughly. That was all a matter of protection against typhoid fever from a rural district, and because, I believed that the supply was endangered by the presence of those two cases in that house, upon the banks of that stream, the dejecta from those patients

being thrown out, as they were, into the stream, they were removed in that way.

Q. When did you make this investigation at Denver?

A. I cannot give you the exact date; but I would say it was in '97 or '98, at the time I was acting as consulting chemist to the Denver Union Water Company,—it was about that time.

Q. State in detail what position the science of bacteriology occupies in regard to the ascertainment of the purity of the river waters?

10987 A. The development of the study of the purity of river waters requires a knowledge of the science of bacteriology, especially in relation to the presence or absence of sewage. The history of the science of the purification of waters shows that at first the clearness of the water was all that was sought after in selecting and adapting a water supply. Later, the science of chemistry was applied to determine the purity of water, and since about '85, the science of bacteriology was developed, and has been applied to its study, so that to-day a satisfactory opinion upon the healthfulness or unhealthfulness of the water supply cannot be passed without a knowledge covering its bacterial contents. The study of the bacteriology of water has to do with the organisms present, and especially with the presence or absence of the colon forms, and forms like it. To-day, what interests in the study of the river water from its sanitary standpoint, is whether or not that river contains sewage.

10988 It is commonly acepted at the present time, that diseases are caused by certain specific organisms, known as bacteria, and among those bacteria which can be borne by water, those of typhoid fever and of cholera are the most prominent. These are intestinal diseases, and, therefore, it is very important to determine whether or not fecal matters find access to the waters; we can use, therefore, the presenc or absence of the intestinal bacteria as the most important index in determining the purity or impurity of the supply.

Q. What position does the science of bacteriology occupy in what is known as sanitary science?

A. The word Sanitary science is a larger term,—Sanitary science embraces primarily a study of the conditions of good health, and the study of foods, air and water.

I have already outlined the importance of the science of bacteriology in ascertaining the purity of river water. The science of bacteriology also occupies an important place in determining the purity, or demonstrating the quality of food supplies.

It would be self-evident that if food became exposed to impure water, the food will be rendered unsafe and unfit 10989 for use; therefore, bacteriological study is an important factor in determining the characteristics of foods.

Q. State in detail what place the science of chemistry holds in regard to the ascertainment of the purity of the river waters?

A. The science of chemistry as applied to river water, has to do with the detemination of the presence or absence of organic matters in the water. It is necessary that we should know the chemical constituents of water, from a sanitary standpoint, and whether it contains organic matter or not; it may or may not be possible to determine the bacterial forms present in the water, but we can determine the presence or absence of organic matters.

The relation of chemical science to the study of the purity of waters, has to do with determining whether organic matters are present or absent. Another province of the application of chemistry to the study of waters, is to determine what changes those organic matters added to the water undergo, after a period of time, so that we have the definite work of chemistry 10990 in determining the presence or absence of organic matters, and secondly, the changes which such organic matters may undergo.

Q. Docs chemistry occupy an important position in sanitary science?

A. It is fundamental to the proper study of foods, of air, the nature of the food stuffs, and the nature of the water supplies the three great necessities of life.

Q. In the ascertainment of the quality of the river water what aid is chemistry and bacteriology to the sanitarian in forming judgment as to the quality and potability of such water?

A. In my opinion the sanitarian could hardly form a proper opinion regarding the quality of a river water did he not have the chemical and bacteriological data upon which to base such an opinion. As, for example, the Platte river, in Denver, is a bright, clear stream coming down from spring waters out of the parks, up on the mountains. It is bright and clear, colorless and sparkling, pushing down over rocks, and no one would hesitate to drink that water. To look at it you would say that the water was entirely satisfactory, an ideal water, but when the bacteriologist comes to examine that water, he finds that 10991 it contains, and carries fecal matters. When the chemist comes to examine it he finds also that there is evidence of sewage borne in the waters, but the bacteriologist's services would be of the greater use there. The water, to look at would be seemingly perfectly satisfactory, but upon applying these several tests, it becomes evident at once that means of purification must be employed before the same can be delivered with safety to consumers.

Q. From the tables of analyses submitted in evidence in this case, by the witnesses for the defense, and which are published in Streams Examinations, which you have examined, at what points in the Illinois River does the nitrifying and purifying processes of the sewage coming from Chicago reach toward practical completion?

A. In studying the tables it is my opinion that the waters of the Illinois River begin to show a very decided purification at Ottawa, which increases and reaches its maximum at *Averyville, which is above* the City of Peoria. It receives, at Peoria, and at Pekin, a considerable addition of sewage material; another area, or a zone of purification commences at that point, some distance 30 miles or so, below, and is practically completed at Grafton, the river at that point appearing to be water of the quality of rivers of this section.

10992 Q. In order to qualify as a sanitary expert is it necessary for such expert to have a knowledge of chemistry and bacteriology?

A. In my opinion it is necessary for a man to have a pretty thorough working, practical knowledge of chemistry and bacteriology in order to qualify as a sanitary expert.

Q. Does not a sanitary expert call to his assistance all information available from chemical and bacterial knowledge, as well as the sources of pollution, in passing judgment on the sanitary character of a river water?

A. In answer to that question I would say that no man

could pass as a sanitary expert who did not seek, in passing upon the quality of a supply, to avail himself of all information possible, chemical, bacteriological, and knowledge of the sources of a supply and all sources of pollution to which it was exposed. Passing upon a supply includes all of those. A man may pass upon a sample of water submitted but he can not thereby necessarily pass upon the supply as a supply. He can say that that sample of water may be good or bad, but he must have a thorough and accurate knowledge of all the conditions gov-
10993 erning a supply, its pollution, its source and the changes to which it is exposed before he can ultimately recommend it or pass an opinion on it.

Q. As a sanitary expert availing yourself of all the chemical and bacterial knowledge which is available to you, which you possess, what is your opinion as to whether a typhoid bacillus, lying in the sediment of a polluted stream, for a period of or in excess of sixty days would be able to cause typhoid fever, if taken into the human system, after it had remained in such sediment for that length of time?

A. From all the knowledge available, from the standpoint of chemical and bacterial knowledge, it would be my opinion that a typhoid bacillus, lying in the sediment of a polluted stream, for a period of over 60 days woudl not be able to cause typhoid fever; for reasons which I have indicated earlier in my examination, it would probably be destroyed in the sediment.

Q. What is your opinion as a sanitary expert as to whether polluted or infected matter, coming from the sewage of Chicago, through the drainage canal, deposited on the bottom of the Desplaines and Illinois River between Chi-
10994 cago and Ottawa and Peoria, can remain there for a period of from 30 to 60 days and yet retain its dangerous qualities as well as pathogenic bacteria?

A. In my opinion polluted and infected matter coming from the sewage of Chicago through the drainage canal, would have become harmless before reaching Peoria and would have been altered so that it would not be deposited on the bottom as sediment as infectious material. The bacteriological data already submitted in evidence, in my opinion and judgment, show the purification of the stream before reaching Peoria.

Q. From your personal knowledge of the Illinois River

and your knowledge as a sanitary expert, together with all chemical and bacterial knowledge, derived from every source, what is your opinion as to whether the sewage from the city of Chicago passing through the drainage canal into the Illinois River, at different seasons of the year, and at different stages of water in the Illinois River, would be a danger and a menace to the inhabitants of the state of Missouri and the citizens of the city of St. Louis using the water of the
10995 Mississippi River for domestic and drinking purposes?

A. The chemical and bacterial data already a matter of evidence in this case, showing that the waters have become practically purified before reaching Peoria, it would be my opinion that sewage from the city of Chicago could not be a menace to the inhabitants of the State of Missouri and the citizens of the city of St. Louis using the Mississippi River water.

Q. What is your opinion as a sanitary expert, based upon your examination of the tables of analysis introduced into evidence by Professors Long, Palmer, Burrill and Jordan of the waters of the Illinois River, the Mississippi River and the Missouri River as represented by such tables as you have examined as to which one of these three rivers from this analysis discloses the least amount of impurity or pollution?

A. By comparison of the data submitted by Professors Long, Palmer, Burrill and Jordan, it is my opinion that the Illinois River at Grafton discloses the least amount of impurity or pollution of the three rivers, the Illinois, Mississippi or the Missouri.

Q. If the Illinois River discloses from such data as
10996 aforesaid the least amount of impurities what would be the effect of the waters of the Illinois River emptying into the Mississippi River at Grafton and subsequently uniting with the Missouri River at its mouth, upon the combined waters of the Mississippi and Missouri rivers at the intake at the chain of rocks?

A. It would be evident that if the Illinois River is of a better quality or does not show as much impurity as either of the other rivers, it would really benefit them, if anything, and in proportion as the waters became mixed. If the evidence should be that the Illinois River practically hugs the east shore and does not mix, particularly it would not affect them. If, on the other hand, the data should show that there is a gradual mixing then in proportion as this mixing occurred to that degree it would improve, if anything. The differences are not very great, however, between the data as I have examined them.

ADJOURNED UNTIL 10:00 A. M., SATURDAY, FEBRUARY 27, 1904.

10997 10:00 a. m., Saturday, February 27, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. E. G. SMITH

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Professor have you made any surveys of the waters of the Mississippi River in passing upon the quality of the Mississippi River for drinking and domestic purposes?

A. Yes, in the course of my professional work and the study of the sanitary character of water supplies I have, from time to time, carried out researches or surveys as stated in your question upon the river, the same extending over a period of at least twelve years.

Q. Will you state in detail at what points on the Mississippi River you have made these researches and for what
10998 purpose.

A. The researches have been made from time to time since before 1890 as problems have arisen in connection with water supplies at several points along the river.

The first place where I have made any examinations is at Brainard, Minnesota. These were made for the water company, a private company that supplies the city of Brainard. Brainard is the first town of any importance on the Mississippi River above St. Paul, about 100 miles above Minneapolis, and having I think about 7,000 or 8,000 population. I was called by the management of the company to investigate the supply as there was some complaint made of the quality of the supply, and they wished to know its quality. I made but one set of examinations for this point, but the examinations showed, as I recall them now, the water of the Mississippi River to carry a large amount of organic matter in solution and suspension.

The next point on the river which I have had occasion to examine was at Minneapolis, Minnesota. I think this was about eight years ago. I was called there by the city engineer to make an examination of the quality of the water and report
10999 upon the same to him. There was a complaint made of the quality of the water and about that time there was considerable sickness in the city and this condition had caused complaint to be made as to the supply as they feared the sickness prevalent at that time was attributable directly to the same. I went there and went over the ground quite carefully with the engineer, visiting the different pumping stations at that time. There were two pumping stations, both taking water from the Mississippi River; one of them was located well above the city, I should say three miles or so, and the other was located in the heart of the city, below the falls, located at this point originally because water power was used to pump the water. Samples were taken from various points, at both the upper and lower pumping stations. They were taken from the taps upon the pumps at both stations and at the upper station samples were secured from the stream directly. I do not recall whether any bacteriological examinations were made from the samples taken from the river at this time, but those samples were
11000 subjected to chemiccal analyses in the chemical laboratory at Beloit. The river at that point was highly colored and was very characteristic of the quality of the waters of the Mississippi in its upper reaches. The waters were dark colored, and owing to the source of these waters coming as they do from the drainage of the swamps in Northern Minnesota, they carried a large amount of vegetable extractive matter in solution and in suspension. At that time the condition was aggravated by the large number of logs floating in the river; large mills having been established near the waterworks; further aggravated the conditions in that the booms for retaining the logs had stretched back so that the surface of the river in front of the station and for some distance above was practically covered with logs. The extractive matter from those logs both as they were stored in the river and from the logs floating above,

contributed to the soluble materials carried by the river and was a prominent factor in our study of the quality of the waters. The analyses of samples were made, and a report was made back to the city engineer in which I called attention to the un-
11001 satisfactory character of the water, its unfitness for a public water supply in its present condition and in the report I advocated their establishing a system of filtration by the city of Minneapolis. This report was published and is in print. It is interesting in this connection to note the quality and know of the impurities present in the water, because owing to the location of the city of Minneapolis and the absence of large towns above the city sewage as we understand it was not an important factor. The river water was highly charged with organic matter, but this in my judgment was due, as stated above, to vegetable extractive matters and was not due to sewage in the sense in which we ordinarily use, i. e., representing dejecta and waste from a population. It is true that rural communities above and the isolated homes with their outfalls along the river contributed something in the way of sewage to the river but it was not an important factor to this study.

The next place upon the river which I have made an examination for is St. Paul. It is located about ten miles below the city of Minneapolis; it does not take its supply from the Mississippi River, and I merely mention it in this connection
11002 because of the unsanitary conditions which were found about the supply and which I called attention to and advocated the removal of. The city itself as well as that of Minneapolis sewers directly into the Mississippi River and these two cities together contribute a large amount of pure animal sewage to the river, so that from this point on the sewage becomes a factor in discussion. At the time I did the work for St. Paul, which was, I think, five years ago, there was considerable typhoid fever in the city and complaints had been made to the health officer and also to the secretary of the board of water commissioners; it was in view of these complaints or the presence of typhoid fever in the city that I was asked to make this investigation.

The next city or point upon the river was the town of Winona. These results and analyses were made some years ago and I merely mention it in passing as one of the towns I have examined. I do not remember the conclusions arrived at.

The next point upon the river which I examined and have studied is that at Dubuque, Iowa, which examination and study was made some years ago, about four years ago, I think, and the studies came up in connection with the purchase of the plant owned at that time by the Dubuque Water Company, by
11003 the city. The investigations included an examination of the river water, a system of filters, the artesian supply and other proposed sources.

The next point upon the river where I have made examinations and a study is at Clinton, Iowa, in connection with the water supply and the desirability of using the same as compared with the use of an artesian well supply. At Clinton, Iowa, the waters were considered unsatisfactory; in view of the facts I recommended the use of an artesian well, and a device by which the objectionable features of the artesian well arising from the presence of sulphuretted hydrogen in the water were overcome.

The particular point where I have studied the river is at Davenport, Iowa. The water is supplied to the city of Davenport, by the Davenport Water Company. Originally the water was pumped directly from the river into a reservoir and from there distributed through the mains. About 1890 the condition had become so unsatisfactory owing to the quality of the water supplied, the same being raw river water, it being muddy, and possessing an odor and a disagreeable taste, a demand was made upon the water company that some method should be taken for the purification of the same. About this time a contract
11004 was made with the old American Filter Company to install the type of filters known as the American System of Mechanical filtration to treat the Mississippi River water and render it suitable for public use. After the plant was installed and was in full operation the management of the company decided that they required expert services in connection with the operation of the same, and I was invited by them to come and make an inspection of the plant and some analyses of the waters in their raw condition and as filtered and to report upon the same. This was, I believe, in 1892, and from that until the present I have made frequent examinations of the Mississippi

River water both in its raw condition and after its filtration, both from the chemical and bacteriological standpoint. These examinations had been made practically at least once a month throughout this period and sometimes oftener. Frequently, during bad conditions of the river, they have been made several times a week. The samples have been taken by the company's representative, both from the raw and filtered waters, in suitable receptacles and sent over to Beloit to me for analyses
11005 and study. The samples for the most part have been
but a few hours in transit and have almost always been collected in the morning and received at Beloit and examined later in the same day. The train service between those two places allowing for a period of between five or six hours from the collection of the samples until the examination. The plant has been changed and enlarged and the process improved from time to time, either at my suggestion or in consultation with me, regarding the proper treatment of the waters of the Mississippi River. For the first portion of the time a period covering perhaps five years or thereabouts only chemical analyses were made, but since that period both chemical and bacteriological examinations of both the raw water and the filtered water have been carried out.

From my knowledge of the Mississippi River water at Davenport, a city of about 35,000 population, receiving the sewage of no considerable town below Clinton, which is about 40 miles above, although there are small towns, and the rural population along the river between these places, I am of the opinion that the Mississippi River at that point is unfit for drinking and domestic purposes in its raw and natural conditions. This opinion is based upon a series of chemical analyses and
11006 later upon a continued series of chemical and bacterio-
logical analyses extending from the period first stated up to the present time. The raw Mississippi River water at Davenport always carries a large amount of dissolved organic matter. The organic matters are of vegetable origin though they may have received some limited amount of sewage which might possibly reach the intake from the rural communities stated or mentioned above. The waters of the river are peculiar and differ markedly from that of any other stream with which

I am familiar in this western country in the amount of this extractive vegetable matter which it carries. We always find in this river, in the raw water, a high oxygen consumption and a relatively high amount of albuminoid ammonia. The nitrogen as nitrates is low, the chlorine is low, usually about 2 to 3 parts per million, and the free ammonia is low, ranging in the neighborhood of 8, 12 or 15 one hundredths parts per million. Another peculiarity of the Mississippi River, which has given some trouble at Daveport, in the efficient filtration of the same, is its varying and shifting character. In the spring of the year, at
the break-up there is always a considerable amount of
11007 sediment in the river continuing into the summer
months. In the fall and winter the waters are not highly charged with sediment, but from March until July, or thereabouts, the sediment increasing as it does, and being of a very fine, silty character, is difficult to remove.

Another factor in the Mississippi river water, which I have noted in the study, is the change in character of the soluble contents, usually in the fall. This is due in my opinion to the mixing of the river water with impounded waters near its headquarters; the water differs entirely for an allotted period following the low water, rendering it for a short period more difficult to handle. This is noteworthy in this connection because of these factors, the silting of the river, the increase of organic matters, the entire change of the dissolved matters introduced, the shifting, in the quality of the water, all of which must be taken into consideration in all waters when discussing their quality.

In my opinion the Mississippi River is unfit for drinking purposes and domestic purposes.

Regarding the bacteriological content of the river aside
11008 from any chemical investigations, I have found that
colon forms of organism are generally present in the water, so that in any sample of the raw water submitted for examination from that point—and there are no sewers from the city of Davenport immediately above the intake—I expect to find indications of the presence of the colon form, or of some of its modified forms.

Another point upon the river which I have studied, is the supply as delivered at Rock Island, Illinois, the intake of which is a short distance below the intake of the Davenport Water Company. I have already given in evidence the conditions of the outbreak, or epidemic of typhoid fever at Rock Island, in 1901, and it was shown at that time that the water supply was in bad condition.

It is to be noted further, that the sewers from Moline, from Rock Island, and from Davenport, the three cities closely situated, and representing a population of about 75,000, empty into the river directly or indirectly at this point; the qualities
of the supply at Rock Island, at least, has been seriously
11009 affected by the same. The city of Moline has to take its
supply from the river directly, and I have advised the establishment of a filter plant at that point to purify the same, as in my judgment the river water in its raw state is unfit for public and domestic use. This filter plant is now installed and will be put into operation soon.

The next point upon the river is the city at Muscatine, Iowa, which takes its supply from the river directly, pumping it into a reservoir, subjecting it to the processes of simple sedimentation. Owing to the outbreak of typhoid fever in the city a few years since, I was called there by the Muscatine Water Company, to investigate the supply, and at that time condemned the river water as being unsuitable for public and domestic use, and at that time advised the changing of the supply, or the purification of the same by a process of filtration. Since that time the works have been sold to the city and I have just completed a report to the Board of Water Commissioners, advocating the use of the system of wells, taking the land supply
from the low land below the city, the river at that point
11010 being in my opinion, based upon analyses of the same,
both chemical and bacteriological, an unsanitary supply, unsafe and unwholesome, and not adapted to public use.

The city of Burlington, Iowa, has had a filter plant installed for several years. The water supply is from the Mississippi river, the same being filtered by a system of gravity filters. These have never been operated satisfactorily, and the plant is now being overhauled with plans to make it conform to the more modern types and more perfect types of filtration. I have been acting as consulting chemist to the company for some time and have advised with them, my advice being based upon an investigation of the local conditions and the chemical and bacteriological analyses of the river at that point.

I have been asked by the Pure Water Commission at Keokuk, Iowa, to investigate their supply, and samples are now in the laboratory at Beloit, for both chemical and bacteriological examinations.

We have also made examinations of the water at Quincy, Illinois, but not very extended examinations.

11011 One more general factor regarding the Mississippi river in determining its quality, should be mentioned, the changes of the river and the qualities of the water of the river due to local floods. This is true particularly at Burlington. The heavy local rains produce changes at Burlington, from washing out of a small creek, situated about three miles above the plant, which materially affect the quality of the supply, making the general river water pumped, much more difficult to handle at times than otherwise.

This is also true at Davenport, heavy rain storms washing out the streams above, and throwing into the river quantities of silt which make the operations of the filter, for the time being, much more difficult and out of the ordinary.

Q. Do all the cities mentioned in your previous answer, whose water supplies you have investigated as above detailed sewer into the Mississippi River?

A. The cities of Minneapolis and St. Paul, of Clinton, Davenport, Rock Island, Moline, Burlington and Quincy,

11012 have systems of sewerage which sewer into the river. There are other cities upon the river which I did not mention, whose water supply I did not study, which add also a considerable amount of sewage to the river. There are other smaller towns and cities adding more or less sewer material, though I cannot state positively as to whether they have regular systems of sewage introduced or not, as at Winona and Keokuk.

MR. JEFFRIES: Now I move to strike out all the testimony of this witness with reference to the sanitary condition of the river at the points and places mentioned by the witness, for the reason that the same is incompetent, irrelevant and immaterial.

11013 Q. From the examinations that you have made of the water of the Mississippi River from Brainard on the north to Muscatine on the south, what is your opinion as to whether the water of the Mississippi River is a suitable water in its raw state for drinking and domestic purposes?

MR. JEFFRIES: I object to the question as incompetent, irrelevant and immaterial, and constitutes no defense in this case.

A. From all examinations that I have made of the Mississippi River from inspections at various points from Brainard and Minneapolis, Minn., to Quincy, Illinois, and from chemical and bacteriological examinations from Brainard, Minn., to Muscatine, Iowa, using these as a basis for the opinion, I am of the opinion that the Mississippi River water, in its raw condition unfiltered, and not treated, is not a wholesome or safe water to use nor one adapted for use as a public water supply.

11014 Q. Does the mixing of the Illinois River with the Mississippi and Missouri Rivers, based upon all the knowledge which you have, both chemical, bacterial and otherwise, create an added danger to the already polluted and contaminated waters of the Missouri and Mississippi River below Grafton, to the inhabitants of the state of Missouri, using the waters of the Mississippi River for drinking and domestic purposes?

A. From examinations of the Mississippi River water made at different times throughout a series of years, and at different points reaching from Brainard, Minnesota, as far down the river as Muscatine, it is my opinion that the Mississippi River water in its raw and untreated condition is unfit for use as a public water supply, without treatment, and it is my opinion, therefore, that the mixing of the Illinois River with the Mississippi River water, after it may have received the Missouri River, does not create any added danger to the inhabitants of St. Louis and to the people of Missouri, for public and domestic purposes.

Q. From all your knowledge of conditions that obtain

11015 in and along the Illinois River, what is your opinion as a sanitary expert as to whether deleterious substances, infected matter or pathogenic germs which come from the drainage canal from the sewers of Chicago would reach as far down the Illinois River as the city of Peoria?

A. From all my knowledge of conditions that obtain along the Illinois River, from the inspection of the river throughout its entire length, from a study of the analytical data, both chemical and bacteriological, already a matter of evidence in this case, from the rate of flow of the river, from the data adduced regarding the duration of life of the pathogenic germs the same not living more than three or four days in the waters of the stream, with the processes of self purification at work, notably the process of dilution and sedimentation, and the chemical and bacterial changes shown, it is my opinion that infected matter and pathogenic germs coming into the drainage canal from the sewers of Chicago would not reach as far down the Illinois River as the city of Peoria.

Q. Would any of those substances in a dangerous state reach the intake tower of the St. Louis waterworks at the chain of rocks, in your opinion?

11016 A. In view of my knowledge of the conditions in and along the Illinois River, the results of the bacteriological and chemical examinations made and submitted already in this case, from the rate of flow of the river, the duration of life of the typhoid fever bacillus, as demonstrated, not exceeding three or four days in the waters of this river, from the agencies of self-purification at work on the stream, notably the factors of dilution and sedimentation and the chemical and bacteriological changes established, it is my opinion that substances coming from the sewers of Chicago through the drainage canal would not reach the intake tower of the St. Louis waterworks at the chain of rocks in a dangerous state.

Q. As a sanitary expert, do you consider the sewage of Chicago, entering the drainage canal and the Illinois River, which in turn empties into the Mississippi River, a menace to the citizens of the city of St. Louis, taking their water supply from the Mississippi River?

A. In view of all the knowledge which I possess upon
11017 the Illinois River, and the study of its physical characteristics, from the study of the chemical and bacteriological analyses of the river already a matter of evidence in this case, from the rate of flow of the river and the duration of life of the typhoid bacillus, the same not extending over a period of three or four days, as already a matter of evidence, from the analytical and self-purification operative in the river, notably those of dilution, sedimentation and the bacterial and chemical changes which the river undergoes, it is my opinion that the sewage of the city of Chicago, entering the drainage canal, and thence discharged into the Illinois which in turn empties into the Mississippi River does not constitute a menace and a danger to the inhabitants of the state of Missouri, or to the citizens of the city of St. Louis taking their water supply from the Mississippi River.

Q. What is your opinion as a sanitary expert as to whether the germ of typhoid fever could lie in the sediment of the drainage canal or upon the bottom of the Illinois River for a period of from one to three years?

A. From the experiments already given upon the life
11018 of the typhoid fever germs in the Illinois River, after the same has received the sewage of the city of Chicago, from the fact that the germs which may have been precipitated to the bottom of the river, in the sediment of the river, would be measurably subject to the same agencies, the same tending to its rapid destruction, it is my opinion that there is no probability or possibility of a germ remainng at the bottom of the river for a period of from one to three years.

Q. Do you know of any instances on record or reference in the literature upon the subject of bacteriology, where a typhoid bacillus has lived for a period of from one to three years in the sediment of a polluted stream, or in the water of a polluted stream?

A. I know of no instance on record or in literature on the subject where a typhoid bacillus has lived for a period of from one to three years in the sediment of a polluted stream or in the water of the same, but on the contrary the records of all the

experiments which I have been able to read, and from all information I have been able to gather upon the subject of the duration of the life of a typhoid fever germ in a polluted
11019 water is that it is brief, being limited to that of a few days, six or seven perhaps, at the outside.

Q. Are you acquainted with Sternberg's experiment on the life of the typhoid in a sealed bottle?

A. I have read of an experiment made by Sternberg upon the life of a typhoid bacillus in sterilized water which had been placed and kept in a hermetically sealed bottle, in which statement it appears that it retained its vitality for a period under that condition for upwards of a year.

Q. What is your opinion as to whether a typhoid bacillus deposited on the bottom of the Illinois River could remain there upwards of a period of five years and then be stirred up by the action of the waves, the winds, steamboats or by any other means, could continue its journey down to St. Louis in a virile state and be a cause of danger to the inhabitants of the state of Missouri using the waters of the Mississippi River for drinking and domestic purposes?

A. From my knowledge of the conditions obtaining in
11020 the Illinois River, from the inspection or the physical surroundings and conditions, from a study of the bacterial and chemical tables already submitted as evidence in this case, from a study of the experimental data concerning the duration of life of a typhoid bacillus in the polluted waters of the Illinois River, the same not covering a period of more than three or four days, as already a matter of evidence in this case, from the rate of flow of the river, and from the agencies of self purification operative in the stream, notably those of the dilution, of sedimentation and of the chemical and bacterial changes induced in the stream, I am clearly of the opinion that by no possibility whatever could a germ be deposited on the bottom of the Illinois River at any point and remain there for a period of five years and then be stirred up by the action of the waves, the winds, steamboats or by any other means, and could continue its journey down to St. Louis in a virile state and be a cause of danger to the inhabitants of the state of Missouri

and the citizens of the city of St. Louis, using the waters 11021 of the Mississippi River for drinking and domestic purposes.

Q. What effect does an increased volume of water in the Illinois River have upon the lowlands lying along the banks of the Illinois River?

A. The banks of the Illinois River being low and shelving especially in the lower reaches of the river, the effect of the increased volume of water would be to overflow these low lands to a considerable extent, and thus we have a greatly increased area of sedimentation, the low lands appearing practically thus as a great settling basin for the waters of the river. This particular feature of the river was very noticeable at the time of my journey down the river, and I noted at various points how widely the river had extended, it at that time being quite high, after some storms, and I understood it was above its normal level and thus covered a large area of territory.

Q. If the increased water at flood tide from the tribu- 11022 taries of Illinois River as well as the Illinois River itself, exclusive of the waters of the drainage canal, causing a large area of land to be overflowed along the Illinois River valley, what effect does this overflow have upon entering the Illinois River through the drainage canal?

A. The effect of increasing water at flood tide from the tributaries of the Illinois River, as well as the Illinois River itself, coming in at points below the entrance of the polluted waters of the drainage canal would and do cause, as I have observed personally, a large area of land to be overflowed along the Illinois River Valley, and the effect of this overflow is to greatly increase the area of sedimentation so that the sewage from the city of Chicago entering the river through the drainage canal would have an opportunity for more complete sedimentation; this overflow forms an important factor in estimating the significance to be attached to the element of sedimentation in the purification from the sewage in the stream.

11023 Q. Would sedimentation be greater if the volume of water were greater, thereby causing a greater area of territory to be overflowed in the Illinois River valley?

A. It is my opinion that if the volume of water be increased overflowing this greater area of territory, the waters discharging out, becoming retarded in their course, and giving opportunity thus for the sedimentation, it would follow that the sedimentation would be greater when the volume of water was sufficiently large to cause the overflow of a considerable section of territory adjacent to the Illinois River through the valley.

Q. Are you acquainted with the different lakes and dams between Chicago and St. Louis, along the Desplaines and Illinois River?

A. I have had opportunities for observing different lakes so called, and the dams between Chicago and St. Louis, along the Desplaines and Illinois River. These dams are five in number and they cause a retardation of the flow of the stream, allowing the water to become more quiescent above them. The lakes so called are not true lakes but are practically expansions of the river where through considerable area the river widens out, forming quite an extended body of water,
11024 and offering opportunities for extensive and decided sedimentation.

Q. Assume that the four dams, the one at Henry, Copperas Creek, La Grange and Kampsville were removed from the Illinois River, would the removal of these dams create a condition in the Illinois River that would permit the sewage coming from Chicago to pass down the Illinois River in an unpurified and infectious condition. to the Mississippi, causing it to be a source of danger to the inhabitants of Missouri using the water of the Illinois River for drinking and domestic purposes, taking into consideration all knowledge which you have, of the chemical and bacterial conditions that obtain between Cheiago and Peoria, and from Peoria to Grafton?

A. From all knowledge which I have been able to gather concerning the conditions which obtain in the Illinois River, from my personal inspection of the river, from the chemical and bacteriological tables already a matter of evidence in this case, from the facts concerning the duration of life of the typhoid bacillus, from the rate of flow of the river from the
11025 agencies of sedimentation and dilution and the chemical and bacteriological changes which obtain in the river, it is clearly my opinion that the removal of the four dams namely the dam at Henry, at Copperas Creek, at La Grange and at

Kampsville would not create a condition which would permit of the sewage coming from Chicago through the drainage canal into the Mississippi River to reach the intake of the water works at the city of St. Louis in the Mississippi River and thereby constitute a menace to the health of the citizens of St. Louis and the inhabitants of the state of Missouri, using the water for drinking and domestic purposes.

Q. Will you state as an expert sanitarian and from all the sources of knowledge that you possess whether the water of the Mississippi River at the chain of rocks was prior to January, 1900, a safe and potable drinking water, fit for domestic purposes in its raw state?

Mr. Jeffries: I object to that as immaterial.

A. With all the knowledge which I have been able to gain upon the question, from my personal knowledge of the 11026 water of the Mississippi River from the conditions as revealed by the chemical and bacterial analyses at various points, conforming as they do to data already a matter of evidence as touching the quality of the water of the Mississippi River at Grafton. From the knowledge of the chemical and bacterial nature of the waters of the Illinois River as they are discharged into the Mississippi River at Grafton, and from the prevalence of typhoid fever as shown in tables already submitted in evidence, in the city of St. Louis it is my opinion that prior to January, 1900, the water of the Mississippi River at the chain of rocks was not a safe and potable drinking water fitted for domestic and drinking purposes in its raw state after the same had passed through the process of purification as adopted by the city of St. Louis in their settling basins.

Q. Was the Missouri River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900?

Mr. Jeffries: Objected to as immaterial.

A. In my opinion the waters of the Missouri River were not a safe water for drinking and domestic purposes prior 11027 to the opening of the drainage canal in January, 1900. The analytical data would show the unsafe and unsatisfactory and unwholesome character of the water.

Q. Was the Illinois River a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900?

A. In my opinion the Illinois River water was not a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900, this being based upon a study of the analytical data, chemical and bacteriological, already submitted and a part of this evidence.

ADJOURNED UNTIL 2:00 P. M. OF THE SAME DAY.

11028 February 27th, 1904.

2:00 o'clock P. M. Session.

Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROFESSOR E. G. SMITH,

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Has the sanitary condition of the Illinois River at Grafton been improved or damaged by the opening of the Drainage Canal?

A. From my study of the conditions of the river, especially from the study of the chemical analyses of the supply of water, and also the bacteriological conditions of the water of the river as disclosed by such analyses from before and after the opening of the Drainage Canal, I am of the opinion that the sanitary condition of the water has not been materially changed by the opening of the Canal.

Q. Have you done any work upon the waters of the Missouri River?

11029 A. In reply to that question I would say that I acted as chemist to the American Water Works Company operating the public water plant at the City of Omaha. This was some years since, perhaps eight or ten years, and I made a series of analyses for that company, the same extending over a period I think of about three years, these being made monthly. The American Water Works Company take their supply from the Missouri River at Florence, about seven miles from the City Hall, at Omaha. I have acted in the same capacity for about two years, for the Water Company at Council Bluffs, Iowa, across the river from Omaha, this company also taking its water from the Missouri river, and pumping it into the reservoirs, then distributing from the same.

Q. What effect, if any, does the sewage discharged through the drainage canal, have upon the waters of the Mississippi river and the Missouri River at the Chain of Rocks?

A. From a study of all the data at hand, and the personal inspection of the physical conditions of the Illinois River, from the study of the chemical and bacteriological analyses of
11030 the waters, of the samples of the Illinois River, already submitted as evidence in this case, from the results of the special study upon the vitality of the typhoid fever bacillus in the waters of the Illinois River, after the same have received the sewage of the city of Chicago, through the Drainage Canal, from the knowledge of the length of time required for the water to flow from the Drainage Canal to the mouth of the Illinois River, at Grafton, from the agencies of self-purification which obtain in this river, being those especially of sedimentation and dilution, and the bacteriological and chemical changes in the course of its flow, I am of the opinion that the sewage discharged through the Drainage Canal, has no material effect upon the waters of the Mississippi and the Missouri Rivers at the chain of rocks.

Such changes as it does effect are those due to the mineral salts carried on by the river, as chlorides, and nitrates. It is my opinion that the sewage as such, does not reach the mouth of the Illinois River in an unchanged condition.

11031 Q. Is the water of the Mississippi and Missouri Rivers, exclusive of the waters of the Illinois, a safe and suitable water for domestic and drinking purposes to be used by the citizens of St. Louis and inhabitants of Missouri, in its raw state, already treated as now, in the City of St. Louis, at the settling basins?

A. From my knowledge of the Mississippi River, and the same after it has combined with the Missouri River, from all data available, from personal studies of the Mississippi River both from personal inspection and chemical and bacteriological studies, I am of the decided opinion that the waters of the Mississippi River, after it has received the water of the Missouri

River, not including the waters of the Illinois River, are not a safe water for domestic and drinking purposes, and are unsuitable to be used by the citizens of St. Louis in its raw state

In answer to the second part of the question, "already treated as now, by the City of St. Louis, with the settling basins," from the statistics of the continued prevalence of typhoid fever in the City of St. Louis, and from the in-
11032 spection of bacteriological and chemical data and from the personal observation of the appearance of the water as delivered to the people of St. Louis, after passing through the settling basins, I am of the opinion that the present treatment of the water by the settling basins merely, does not render the same a safe and suitable water for domestic and drinking purposes, to be used by the citizens of St. Louis.

Q. In order to make the water of St. Louis a safe and potable drinking water for domestic and drinking purposes, how should it be treated?

MR. JEFFRIES: I object to the question as immaterial.

A. In my opinion, in order to render the waters of the Mississippi River safe after they have received the waters of the Illinois River, at Grafton, and the Missouri River, at its mouth, the same passing down by the Chain of Rocks, the proper method to treat that water would be by some process of efficient filtration.

MR. TODD: Q. What experience have you had, aside
11033 from what you have already detailed in evidence, in connection with the installation of filter plants?

A. In the course of my studies and investigations upon the purification of public water supplies, I have had to do, as consulting chemist, with some plants already mentioned in my evidence, and in addition to the same, with the filtering plants at Denver, Colorado, at Brooklyn, New York, at Indianapolis, Indiana, and in addition to those plants, I have had to do as consulting chemist with perfecting, and improving the process, and the enlargement of plants at other points.

Q. What other points?

A. Of improving, of operating, or testing the plants at other points, such as Binghampton, New York, Portage, Wisconsin, and Eau Claire, Wisconsin, Kankakee, Illinois, at Stevens Point, Wisconsin, and Oshkosh, Wisconsin.

The nature of the services rendered at these plants has been that of consulting chemist and has had to do with the installation of new plants, to determine the efficiency of those in operation, and advise with the management in the efficiency and operation of the same.

11034 Q. Has your business connection with filtering plants extended to the question of cost of filtration plants and the expense of operating the same?

MR. JEFFRIES: Objected to as immaterial.

A. I think I may say that I have never yet been called into consultation as to any filter plant where the question of cost of operating the same was not raised.

In the matter of the installation of new plants and advising concerning them, the cost of installation and the cost of operating the same is one of the important questions always brought up for consideration, and upon which an opinion is expected.

Q. Did the fact that the Drainage Canal was opened in 1900, create any greater necessity for the filtration of the waters of the Mississippi River at St. Louis, since 1900, than existed prior to that time, in order to secure a safe and potable drinking water for the citizens of St. Louis?

A. From my studies of the Sanitary quality of the waters of the Mississippi River, I am decidedly of the opinion 11035 that the Mississippi River water in its raw condition is unfit for use for a safe and wholesome public water supply without being subjected to processes of purification by filtration. This conclusion is obtained through all my knowledge of the river from personal study and from chemical and bacteriological examination of the same, and that too, not at a single point, but at different points in the river reaching from Minneapolis, Minnesota, where its supply is taken from the river, and where I recommended extensive and efficient filtration of the water.

The introduction of the Illinois River would not cause me to recede from that position, as in my opinion it does not materially affect the quality of the Mississippi River, after the Missouri River is introduced into the Mississippi River.

The known dirty condition of the water from the amount of silt and sediment which it carries would in my judgment only make more desirable and more necessary the purification of the waters of the Mississippi at St. Louis, by filtration.

11036 Q. In the event that a filter plant should be established at St. Louis for the purpose of filtering the water of the Mississippi river, which includes the combined water of the Mississippi and the Missouri rivers, would the installation of such a plant in your opinion cost any more to build and construct and operate, with the waters of the Illinois, since the opening of the Drainage Canal, emptying into the Mississippi river, *than it would prior to the opening of the Drainage Canal?*

MR. JEFFRIES: I object to that as immaterial, and having no bearing upon the issues involved in this case.

MR. TODD: In reply will state that the question of filtration is a matter that has been introduced into this record by the complainant in this case, and has a material bearing on the case as presented by the testimony of the complainant, as evidenced by the testimony of Prof. Sedgwick, Mr. Fuller and Mr. Hazen.

11037 Q. In the event that a filter plant should be established at St. Louis for the purpose of filtering the water of the Mississippi river, which includes the combined water of the Mississippi and Missouri rivers, would the installation of such a plant, in your opinion, cost any more to build and construct and operate with the waters of the Illinois, since the opening of the drainage canal emptying in the Mississippi river than it would prior to the opening of the drainage canal?

A. From my knowledge of the Mississippi river as based upon personal investigations and chemical and bacteriological examinations of the same, and from my study of the analyses of the Illinois river at Grafton, before the waters of the same are discharged into the Mississippi river water I am very clearly of the opinion that the cost of purification of water below the mouth of the Illinois river would not be increased, owing to the waters of the drainage canal finding access to the river, and therefore the cost of installation and operation of a filter plant at the City of St. Louis would not be increased owing
11038 to the admission of waters from the drainage canal.

Q. In the construction of such a filter plant at St. Louis which one of the waters of the three rivers, the Illinois, Mississippi or Missouri, if treated with a filter plant, would cost the most for filtering?

A. The answer to the question can not be made in brief. It involves the whole question of the type of filter most desirable to use, whether a mechanical filter or a system of slow sand filtration, the amount of previous treatment by sedimentation; an exact answer to that question, involving as it does these rivers, could be made only after a series of experiments upon the rivers themselves, and upon a large scale. As an illustration the cost of purifying the Ohio river at Cincinnati was determined only after a large experiment, and also after an elaborate series at Louisville, Kentucky, also after an elaborate series of experiments upon the Alleghany river in determining the treatment of the water supply at Pittsburg, the Alleghany forming one of the tributaries; the proper course to pur-
11039 sue at New Orleans, the type of filtration to be adopted, was determined only after an elaborate series of experimentation. Therefore, the full answer to that question involves data which is not at hand.

Q. If a filter plant should be established at St. Louis to filter the combined waters of the Illinois and Mississippi and Missouri rivers, would such a plant require any change in its construction or management if the drainage canal should be closed?

A. From my knowledge of the quality of the Mississippi river water and the difficulties met with in successfully filtering the same; from personal studies upon filter plants and upon the river; the water of the Illinois river at Grafton being so similar to the waters of the Mississippi river; the waters of the Illinois river at Grafton being, in my opinion, essentially the same as they were before the waters from the sewage of Chicago were delivered from the drainage canal into the Illinois river, I am clearly of the opinion that the role which the drainage canal plays in the Illinois river would not affect the cost of installation, management or operation of a filter plant filtering
11040 the waters of the Mississippi river at St. Louis after the same have received the Illinois river at Grafton and the Missouri at a point below.

Q. If such a filter plant should be established at St. Louis would the cost of operation be increased because of the opening of the drainage canal over conditions that would obtain if the same was not opened, and would it require any more skillful and expensive operators to work the filter with the drainage canal opened than if the drainage canal was closed?

A. From my knowledge of the quality of the Mississippi river water and the difficulties met with in properly filtering the same, from personal study and observation at other points, and from my knowledge of the quality of the Illinois river at its mouth, as disclosed by observations, both chemical and bacteriological, made both before and after the drainage canal was opened, the same showing the Illinois river to be essentially of the same general character as the Mississippi river water, I am clearly of the opinion that it would not cost any more to operate a filter plant or require more skill and expensive management of the same after the sewage of the City of Chi-
11041 cago had passed through the drainage canal into the Illinois river and thence into the Mississippi river water above St. Louis than before the drainage canal was opened.

Adjourned until 10:00 a. m., Monday, February 29, 1904.

11042 10:00 a. m., Monday, February 29, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

No witnesses being present an adjournment was taken until 10:00 a. m., Tuesday, March 1, 1904.

11043 10:00 a. m., Tuesday, March 1, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. E. G. SMITH,

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Have you made a table of averages, based upon the analytical data presented in evidence in this case, by Professors Jordan, Long and Palmer, from points at Joliet, LaSalle, Averyville, Beardstown, Grafton, the Missouri river at West Alton, the Mississippi at Grafton and the Mississippi at Alton and the Mississippi at the intake tower of the St. Louis waterworks?

A. I have prepared tables showing averages of chemical analyses from samples taken from the Desplaines, at Joliet, the Illinois river at LaSalle, Averyville, Wesley, Beardstown, Grafton, the Missouri river at West Alton, the Mississippi at Grafton and the Mississippi at Alton, 100 feet from shore and at the intake at St. Louis, the same being averages from chemical
11044 analyses, in the reports of Streams Examinations,
the analyses, as stated therein, being made by Mr. Jordan during the months of May and June, 1899, and during the months of May and June in 1900, by Professor Palmer in the months of June, July, August and September, 1899, and during the months of June, July, August and September, 1900, and by Professor Long during the summer months of 1899 and the summer months of 1900, the same being taken as reported by Professor Long in the publication of the Illinois state Board of Health, Sanitary Divisions of the Illinois river and tributaries, dated 1901, the tables from which the data for this table is made having already been introduced in evidence.

In this table there is included the locality, the observer, the nitrogen as free ammonia, the nitrogen as albuminoid ammonia, dissolved, suspended and total; nitrogen as nitrites, nitrogen as nitrates; total nitrogen; oxygen consumed and chlorine.

All of these data have not been determined by all of these three observers.

11045 Q. The data obtained in the tables are taken from the analytical tables heretofore mentioned by you, and general averages made by yourself?

A. The data are made from these tables and the averages made by myself.

Q. Will you please read the table which you have prepared from the analytical data of Jordan, Long and Palmer as heretofore testified to by yourself?

A. The table is as follows:

Locality.	Observer.	Nitrogen as Free N H_3		Nitrogen as Albuminoid Amm'nia						Nitrogen as Nitrites.		Nitrogen as Nitrates.		Total Nitrogen.		Oxygen consumed.		Chlorine.	
				Dissolved.		Suspended		Total.

11047 Q. Professor, will you please explain the table that you have just read into evidence and its significance, viewed from the standpoint of a sanitarian?

A. This table was prepared to throw some light upon the condition of the Illinois river in its upper reaches, and also such chemical changes as the river underwent as it passed down at the various points indicated in the first column of the same.

It was also designed to bring out a comparison between the waters of the Illinois river as delivered at the mouth of the Illinois into the Mississippi at Grafton with the quality of the waters of the Mississippi at Grafton, and at two other points down the stream. It was prepared to show what changes the stream underwent, the same being extended over considerable reaches of the river. The data here introduced are taken from the report on Streams Examination, and from Professor Long's report in the Illinois State Board of Health for 1901, and are those which we take in special consideration in determining the sanitary character of the water and the changes it undergoes from a chemical standpoint.

One of the most important data is the consideration
11048 of the presence of nitrogen, and its various stages of oxidation. Sewagic matters are rich in nitrogen and it becomes therefore of the utmost importance to determine not alone the presence of the nitrogen but also any changes the same may have possibly undergone. Nitrogen may be present in nitrogenous organic bodies, and in the process of slow decomposition in contact with air the nitrogenous bodies will break down into ammonia, which may subsequently become oxidized into the condition of nitrous acid and later into the condition of nitric acid. Free nitrous acid may be present in the water, but more probably as nitrites. The nitric acid is present in the waters as the dissolved salts, the so-called nitrates. Therefore, nitrous acid is always stated as nitrogen as nitrites and nitric acid as nitrogen as nitrates.

Chemical analysis, therefore, has to do with the determination of nitrogen present as undecomposed nitrogenous organic compounds; also with the nitrogen which may have undergone its first stage of decomposition into ammonia, with nitrogen as nitrites, and nitrogen as nitrates.

11049 Referring to these particular tables, I find that Professor Jordan uses an expression, "nitrogen as free ammonia." Professor Palmer, "nitrogen as free ammonia." Professor Long in his tabulations speaks of the ammonia as free ammonia. The tables showing this statement, namely of the ammonia, Professor Long's free ammonia or albuminoid ammonia, could be converted easily into nitrogen as free ammonia by diminishing all of his data upon ammonia or albuminoid ammonia by 3-17ths. The present statement, however, does not affect the interpretation of Professor Long's analyses or the significance to be attached to the same.

The study of nitrogen in these various conditions from albuminoid ammonia to free ammonia, to nitrogen as nitrites, and nitrogen as nitrates, therefore, present the condition of nitrogenous organic bodies in the various stages of decomposition of nitrogenous matters which may have been present. The albuminoid ammonia being an index of the undecomposed or partly decomposed nitrogenous matters, the ammonia where the decomposition has gone to such a point as to eliminate the nitrogen as nitrites indicating further change of the free ammonia, and the nitrogen as nitrates representing the ultimate stage of the oxidation of the nitrogen.

11050 The column of total nitrogen which was used only by Professor Palmer would represent the total nitrogen present in these different states of oxidation.

By oxygen consumed we understand the power of a water to absorb oxygen from an oxidizing material. This test for the presence of organic matters in water has been used for many years, and in fact was used before the introduction of the so-called albuminoid ammonia process. Historically the amount of oxidizable matter in the water was taken as an indication of the general purity or impurity and its suitability for public drinking and domestic purposes.

At the present time, however, it does not form the only index of the purity or impurity of the water and the sanitary character of the same, but it is one of the indices we use in valuing the quality of a supply.

The significance of the nitrogen consumed lies in the fact that it represents the amount of the oxygen which would be taken up from oxidizing agents by materials dissolved in the

water. These may be made up of other material capable of oxidation, but inasmuch as the organic matters in our western streams form practically the whole of such oxidizable
11051 matters the oxygen consumed is an index of organic and not inorganic pollution.

In waters from some other sources the oxygen absorbed by the water may point to inorganic contamination, as, for example, in waters from artesian wells which carry considerable amount of sulphurretted hydrogen or of metals in lower state of oxidation, such waters will absorb oxygen from oxidizing agents, but this is not true of waters exposed to the air as in the case of our open streams.

It is a general and important fact to bear in mind that waters may have a high oxygen consumption and yet reveal a relatively low content of nitrogen in its various stages of decomposition. This is true, in a general way, of waters coming from our northern country which require a large amount of potassium permanganate, the agent usually employed in carrying out this test; but strictly sewagic waters carrying a high nitrogen content may also require a large amount of ogygen to oxidize and destroy the organic matters.

Chlorine is taken also from these tables as an important index of the condition of a stream. Chlorine represents, generally, in our streams, common salt, not harmful in and
11052 of itself, but very important in studies of this kind as salt is the constant friend of, and accompanies sewage. The chlorine determinations, therefore, are of importance in estimating the sanitary character of a stream.

With this explanation of the terms employed in the original determinations and their significance, it is of value to note in this table of results which we have, showing the averages of analyses taken from the Desplaines, at Joliet, from the Illinois river, at LaSalle, Averyville, Wesley, Beardstown and at Grafton, from the Missouri at West Alton, from the Mississippi at Grafton, from the Mississippi at Alton, 100 feet from shore, and from the intake at St. Louis, a very high pollution from sewagic matters in the waters of the Desplaines at Joliet, the same gradually diminishing as we pass down the river as far as Averyville, showing an increased pollution at Wesley and again diminishing gradually until Grafton is reached, at the mouth of the Illinois river.

While the data as given by the different men for the periods indicated, namely Palmer for June, July, August and
11053 · September, for the years 1899 and 1900, and Jordan for
the months of May and June, 1899 and 1900, and Long during the summer months of 1899 and 1900, are not strictly comparable, yet in no essential point do they differ the conclusions which can be drawn from any one of these observers pointing clearly to the chemical purification of the waters of the Illinois river by the time they have reached Grafton, as indicated by a diminution in the amounts of free ammonia, in the amounts of albuminoid ammonia, the notable increase in nitrates, the diminution in oxygen consumed and in the diminution in the amounts of chlorine.

Another important fact is that the results of 1900 as compared with those of 1899 show at Grafton a diminution in the amounts of free ammonia, a dimimution in the amounts of albuminoid ammonia, a diminution in the amount of nitrogen as nitrites, but an increase in the amount of nitrogen as nitrates, a diminution in the amount of oxygen consumed and the chlorine showing an increase by Jordan, a decrease by Long and a very slight increase by Palmer.

In a word the important fact brought out is that the waters have undergone a practical degree of purification when
11054 they reach Grafton, and the analytical data clearly show
that the water in 1900 was of a quality superior to that in 1899, for these dates given.

Applying the same principle to the averages of the results of waters taken from the Mississippi river at Grafton, it is my opinion that the waters of the Illinois river at Grafton, as they empty into the Mississippi river, are better than the waters of the Mississippi river taken from the river at a point above Grafton.

Applying the same principles of interpretation of the analyses, it is my opinion that the waters of the Illinois, as delivered into the Mississippi river at Grafton, are of a quality, upon these dates for which these averages are given, and they were the only dates from which data were available, which covered similar periods and similar seasonable fluctuations of the stream), and comparing these data the waters of the Illinois as delivered into the Mississippi at Grafton, are upon the whole a better water, chemically, for drinking and domestic purposes than the samples taken from the intake at St. Louis, the water of the intake of St. Louis being the waters of the Mississippi river after it has received the flow from the Illinois and the Missouri rivers.

11055 Q. Have you examined the bacterial tables introduced in evidence and found in streams examinations, by Professor Jordan, and Professor Burrill?

A. I have studied these bacterial tables as submitted by Professors Jordan and Burrill, and have made a tabulation of results as given by them in their tables, which is already a matter of evidence.

Q. Will you read into evidence the tabulation of results, prepared by you, based upon the bacterial tables of Professors Jordan and Burrill?

A. The table is as follows:

11056

Some data bearing on the bacterial condition of the Illinois river at its worst state, viz., during the four months in the beginning of 1900.

	Morris.	Averyville.		Grafton.		Mississippi River --Grafton.	
	....	2	53,000	......	....	... ..	....
Jan. 10	1,224,000	9	9,100	4	2,600	4	200
16	1,200,000	16	58,800	10	3,300	10	2,400
26	1,230,000	23	51,000	17	29,600	17	8,000
29	290,000	29	147,000	24	58,500	24	15,200
	....	......	....	31	22,800	31	18,000

	99,746,000		1,287,500		470,800		707,000
Average	600,125		75,735		29,375		44,187

11057 Q. Will you state how these tabulations were made and what they indicate?

A. These tabulations were made by myself from Dr. Jordan's tables as given in the report on Streams Examination, and were taken by me from those tables, as covering the worst conditions of the river in its lower reaches, endeavoring to get some view of the water in the conditions which those tables show to be the worst. These were copied off by myself, upon paper, and were then copied by myself on the typewriter, and verified.

There were four points only selected, one of those points being at Morris, Illinois, representing the river in its upper stretches; the second was from Averyville, where the data have shown a sanitary purification. The third was from Grafton, at the mouth of the Illinois river, and the fourth is from the Mississippi river at Grafton, the samples being taken from a point above the outlet of the river into the Mississippi river. These data were taken from the results given by Dr. Jordan during the months of January, February, March and April.

I note upon studying the results that at Grafton and Averyville we had a low count as compared with the waters in the upper part of the stream, the numbers at the beginning
11058 of January being low, a few thousand at Grafton, for instance, in the Illinois river, the lowest count being 2600, and in the Mississippi river at Grafton being 200; the first day at Averyville for the same date being 55,000, that being higher, for the following number on the 9th being but 9,000.

I note also that towards the end of April there was a decided diminution in the number of bacteria, the numbers at Grafton at the end of April having fallen down to the condition they were at the beginning of the year, and at Averyville there being about the same number, and at Morris the numbers having also fallen off.

I took that, therefore, as fairly indicative of the river at the worst period which I have noted bacteriologically, so far as these tables go, being the months of January, February, March and April of 1900.

The averages which I shall give presently seem to me, therefore, to fairly represent something concerning the actual condition of the river throughout this period. It was not subject to seasonal changes, the conditions at that time of the year being much more uniform, and not going beyond the first
11059 of May, it would be evident that it would not be subject to seasonal changes for through this period we have a practically uniform condition, especially of the river in its lower stretches, as at Grafton.

From this table it will be noted that the total number of bacteria at Morris run very high, being over a million the first three days in January and twice in March. The numbers at Averyville reached, one time in February, 210,000. At Grafton a number reached once was 84,000, and in the Mississippi river the number on two different dates, running as high as 170,000 and 140,000, but it will be noted from a study of the tables that in both the cases at Grafton and the case in the Mississippi river we have a small number at the beginning of this tabulation and a small number at the end. The intermediary numbers run uniformly much higher.

By making the averages for this period which in my judgment is comparable, as the condition of the stream was probably quite uniform throughout the period, I find that at Morris there were an average of 609,125 bacteria per cc. and at Averyville there were 75,535; at Grafton there were 29,375 and at
11060 the Mississippi river at Grafton 44,187, this being the
averages of the analyses taken upon sixteen dates from Morris, Grafton, at the Mississippi river, and for seventeen days at Averyville. These are the worst conditions of the river and are interesting as comparing the conditions at that time.

Q. What conclusion, based upon the bacterial table, just introduced, do you draw as to the comparison from a sanitary standpoint of the Illinois river at Grafton with the Mississippi river at Grafton?

11061 A. From a study of these tables, these tables being the results of the investigations of the samples of water on these different dates of the Illinois river at Grafton and the Mississippi river water at Grafton, I am of the opinion that so far as numbers of bacteria are concerned, the waters of the Illinois river at Grafton are of a better quality than the waters of the Mississippi river at Grafton.

Q. Have you examined the reports of Professor Jordan in Streams Examinations, which have been verified and offered in evidence in this case, and the bacteriological data from the tributaries of the Illinois river, the Illinois river and the Mississippi river at Grafton, and have you made a tabulation of the same?

A. I have.

Q. Will you produce and read such tabulation as you have prepared, in evidence?

A. The table that I have prepared is as follows:

11062 Some bacteriological data regarding rivers being averages of the number of bacteria for the first four months for the year of 1900 as given by Jordan in Report of Streams Examination:

Desplaines river, Lockport,	Ave. of	15,625	per c. c.
Kankakee river, Wilmington,	" "	16,162	" "
Fox river, Ottawa,	" "	34,480	" "
Big Vermillion, LaSalle,	" "	23,900	" "
Sangamon, Chandlerville,	" "	33,106	" "
Illinois, at Grafton,		29,375	" "
Mississippi, Grafton,		44,187	

Desplaines,	15,625	
Kankakee,	16,162	
Fox,	34,480	34,480
Big Vermillion,	23,900	23,900
Sangamon,	33,106	33,106
	123,273	91,486
Ave.,	24,656	30,495
Illinois,	29,375	
Mississippi,	44,187	

11063 Q. Will you state what that table shows that you have just read in evidence and what sanitary significance do you attach to it?

A. This table was made up from averages of results as stated by Jordan in his Streams Examination, the average being made by myself, the period covered being from the first of January in 1900 to the end of April of the same year, the same being intended to cover a period similar to that covered by the data introdced in the previous table.

The data in this table are averages of the results as given by him of samples of water taken from rivers tributary to the Illinois. As the results of such analysis I find that the average number of bacteria in the water of the Illinois at Grafton is a little above that of the average of these streams, namely the Desplaines River at Lockport, the Kankakee at Wilmington, the Big Vermillion at LaSalle and the Sangamon at Chandlersville, and the Fox at Ottawa.

It is to be noted that two of these rivers, the Fox river at Ottawa and the Sangamon at Chandlersville, carry a number of bacteria in excess of that of the river at Grafton.

11064 The water of the Big Vermillion is in bacterial content about the average of the five rivers, the Desplaines, the Kankakee, the Fox, the Big Vermillion and the Sangamon, the water of the Desplaines river at Lockport and the Kankakee river being below the average. The waters discharging into the upper part of the Illinois river are therefore lower than those in the lower reaches of the river. Averaging the five rivers together I find that the total number of bacteria per cc. in these waters to be 24,656. I find, averaging the last three, the Fox, the Vermillion and the Sangamon, the average is 30,495 throughout this same period. The Illinois river at Grafton is 29,376, the average of the Mississippi river at Grafton, for the same date, being 44,187. The waters of the Mississippi river are not included in this average. It is my opinion, therefore, that the bacterial condition of the water of the Illinois river at Grafton, from such studies as this, is fairly comparable with the waters emptying into the stream at this season through the same period. It is better bacterially than the average of the waters of the Mississippi river taken at Grafton through this same period.

Adjourned until 2:00 p. m., same date.

11065 2.00 p. m., Tuesday, March 1, 1904. Continuation pursuant to adjournment.

Present, the Commissioner, and same counsel representing the respective parties.

PROF. E. G. SMITH,

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Have you made a comparison of the bacteria flow of the Illinois river at Grafton with the flow of the Mississippi river at the same point and points below as given in tables submitted by Professor Jordan, in the report of Streams Examinations which have been already introduced into evidence?

A. I have prepared such a table, a table representing the bacterial content of the waters at Grafton, being at the mouth of the Illinois river.

Q. Will you produce and read such table in evidence?

11066 A. The table is as follows:

A comparison of the bacterial flow of the Illinois river at Grafton with the flow of the Mississippi river at the same point and points below as given in the tables submitted by Jordan in the Report of Streams Examination. Average of the counts for the first four months of 1900 when in the worst condition.

Illinois river at Grafton	29,375 per c. c.
Mississippi river at Grafton	44,187 " "
" " " Alton 100′ from Illinois shore	43,906 " "
" " " Alton one-fourth distance from Illinois shore	69,919 " "
Mississippi river at Alton, mid-stream	78,044 " "
" " " Alton one-fourth distance from the Missouri shore	82,294 " "
Mississippi river at Alton, 100′ from Missouri shore	64,233 " "
Mississippi river at Chain of Rocks, 400′ from Illinois shore	53,100 " "
Mississippi river at Chain of Rocks, midstream	69,825 " "
" " " Chain of Rocks, inlet tower	58,309 " "
" " " Chain of Rocks, 400′ from the Missouri shore	73,791 " "
Missouri river at Fort Bellefontaine, West Alton, Mo.	56,035 " "

11067 Q. From the table of bacterial comparison which you have just read, will you state what sanitary significance you attach to this table as showing the comparative pollutions of the Illinois, Mississippi and Missouri rivers?

11068 A. From a comparison of the data submitted in this table, representing the bacterial flow of the Illinois river at Grafton with the flow of the Mississippi river at the same point, and points below, as given in the table submitted by Professor Jordan in the report of Streams Examination, I find from the average of the counts of the bacteria for the first four months of 1900, which months according to my study of the tables represent the rivers in their worst condition, it is my opinion that the Illinois river as indicated by these tables is better in the number of bacteria contained in the same than the Mississippi river at

Grafton or the Mississippi river at Alton, 100 feet from the Illinois river, or at the Mississippi river at Alton, ¼ distance from the Illinois shore, or the Mississippi river at Alton, in midstream, or the Mississippi river ¼ distance from the Missouri shore, or the Mississippi river at Alton 100 feet from the Missouri shore or the Mississippi river at the chain of rocks, 400 feet from the Illinois shore or the Mississippi river at the chain of rocks in midstream, the Mississippi river at the chain of rocks at the intake tower, the Mississippi river at the
11069 chain of rocks 400 feet from the Missouri shore and from Bellefontaine, West Alton, Missouri.

This table indicates the much larger number of bacteria at these points than from the Illinois River at Grafton, this covering, as already stated, the first four months of 1900, taken from the tables; the river appears to be in its worst condition during the period which the table covers.

Q. What is your opinion as an expert chemist and sanitarian basing that opinion upon all the knowledge which you possess as well as interpreting the series of tables offered in evidence by Professors Jordan, Long and Palmer, of the waters of the Illinois River as to whether the pollution and contamination from the sewers of Chicago emptying into the Chicago River and thence into the Drainage canal continues to be manifest and present as far down the Illinois River as Grafton and at the Chain of Rocks on the Mississippi River?

A. From all knowledge available, from a study of the chemical tables in evidence by Professors Jordan, Long and Palmer, of the waters of the Illinois River, as well as all knowledge available to me in passing an opinion, the same
11070 being derived from a personal inspection of the river, from a study of the bacterial as well as the chemical data, I am very clearly of the opinion that pollution and contamination from the sewers of Chicago emptying into the Chicage River and thence into the drainage canal and so out into the Illinois River does not continue to be manifest and present as far down the Illinois River as Grafton, but on the contrary it seems to me that the agencies operating in the self purication of the stream, especially the agencies of dilution and sedimentation, of the bacterial and chemical changes which obtain in the stream, the duration of the life of the typhoid ba-

cillus, the data already being in evidence in this case, and the flow of the river, the combination of these agencies all tending to practically purify the river so that sewage as such does not reach down the Illinois River as far as Grafton; and, further, if for the above reasons in my opinion the contamination, and the pollution from the sewers of Chicago do not obtain in the Illinois River at Grafton, such contamination and pollution cannot be manifest and present from the Illinois River at the chain of rocks in the Mississippi River.

11071 Q. Were you acquainted with the Illinois River at Peoria prior to January, 1900?

A. In the course of my sanitary work I was asked by the Peoria Water Company, at the time of the installation of the new plant in 1892, to assist them in the determination of the best supply available for such new plant, and in the course of the analysis made at the time I made some analyses of the Illinois River and some investigations upon the subject.

Q. What was the condition of the Illinois River in 1892?

11072 A. In the course of the investigation made at that time the river was, in my opinion, unfit for use as a public water supply, and at my advice the company dropped the consideration of the stream for that use.

Q. How does the condition of the Illinois River at Peoria now or since 1900 compare with the conditions that obtained at the time you made these examinations for the Peoria Water Company?

A. In my opinion the water at the present time is of a better quality than it was at that time, in 1892.

Q. Describe the appearance of the water at that time?

A. In the course of those investigations I was upon the river in a boat and went out to and was across the wagon bridge observing the river from time to time, and samples were taken for chemical analysis from the river. It was of a dirty appearance as I recall it, and possessed, in warm seasons, a decidedly disagreeable odor.

Q. When was the last time you observed the Illinois River at Peoria?

A. The last time I observed the river at Peoria was in September of 1903.

11073 Q. In appearance how did the river compare in September, the time that you observed it last, with the conditions that obtained in 1892?

A. At the time I was there in September there had been a rain storm just preceding it, and the river was muddy and so much silt in it I do not think I could institute a comparison, further than that at the time I was there in September it was muddy from previous rains. There was no odor observable, in September, nor was the water offensive to sight or smell, beyond the presence of the mud and silt in the stream.

I remember going across the bridge in 1892, when there was a flood in the river, in the spring time, and the river was dirty and muddy and riley, although I made no chemical analysis or examinations of the water at this particular time, with the mud and silt in the water.

Q. Will you state, as a sanitary expert, basing your opinion upon all the information you possess in this case whether in your opinion the water supply of St. Louis is contaminated, polluted or injured by the sewage of Chicago entering the drainage canal and from thence into the Illinois River?
11074

A. As a sanitary expert, basing my opinion upon all the information which I posses in this case, such information being derived from the study of the physical properties of the stream from a personal examination of the same throughout its entire length, from the mouth of the Chicago River to the mouth of the Illinois at Grafton, from a study of all bacteriological and chemical data which have been submitted in this case, from a knowledge of the experiments regarding the vitality of the typhoid bacillus, the experiments being carried out in the waters of the Illinois River, after the same has received the sewage of the city of Chicago, by way of the Chicago drainage canal, from the rate of flow of the river, from the study of the agencies operative in the self-purification of the stream, consisting of dilution, sedimentation, all chemical and bacteriological changes affected in the same, from the comparison of the data of the waters through the upper reaches of the River after it has received the sewage of the City of Chicago through the drainage canal, the comparison of the results, both bacteriological and chemical, at Averyville and after the river has 11075 received the sewage of the city of Peoria and smaller towns, and the quality of the water of the river as evidenced by the analyses made at the city of Grafton, near the mouth of the Illinois River, and comparing the same with the data at hand regarding the quality of the Mississippi River, and my personal knowledge of the habits of the stream and the sanitary quality of the waters of the same, and from an examination of the data regarding the quality of the Missouri River, I am of the opinion that the water supply of St. Louis is not contaminated, polluted or injured by the sewage of Chicago entering the drainage canal and thence into the Illinois River.

Q. From your examination of all the analytical data in this case as heretofore introduced by the witnesses for the defense, what is your opinion as a sanitary expert and chemist as to whether any of the original organic matter of the sewage from Chicago finds its way into the intake tower at the St. Louis water works, chain of rocks?

A. My examination of all data which I have been able to gather together, which bears upon this case, from a study of the tables submitted by witnesses for the defense in this case, from my knowledge of the conditions of the Illinois River throughout its entire length, derived from the personal inspection 11076 of the same, from the data regarding the viability of the typhoid germ and the period of time necessary for water to flow from Chicago to St. Louis, and from my study of the agencies operative in the sanitary purification of this stream, from the chemical and bacteriological changes which obtain through the course of its flow, it is my opinion that sewage from the city of Chicago becomes practically purified at Grafton and the quality of the Illinois is fairly comparable with that of streams forming its tributaries, and that the sewage of Chicago has become purified practically, the pathogenic bacteria having been eliminated in the process of flow of the stream, and hence the original organic matter of the sewage from Chicago does not find its way into the intake tower of the St. Louis water works at the chain of rocks.

Q. Will running water purify itself so as to be free from pathogenic bacteria that may be placed therein?

A. From studies which I have made upon the question as to self purification of running streams, I am very clearly of the opinion that running water can and does purify itself so as to be free from pathogenic bacteria which may have been placed therein.

11077 Q. Since your opinion as an expert upon water supplies as to whether or not the waters of the Mississippi River was at the center of the main channel of the said river, below the mouth of the Illinois River and down to the intake tower of the St. Louis Waterworks at the chain of rocks are less valuable for drinking purposes and more liable to carry water borne diseases, such as typhoid fever and cholera now than they were before the sewage from the sanitary district of Chicago was run into it, from the drainage canal, and through it into the Illinois River?

A. From all the knowledge which I have upon the sanitary quality of the Mississippi River after the same has received the waters of the Illinois River, from the fact that the agencies of self purification of a running stream obtains in the Illinois River, from the fact that in my opinion the waters of the Mississippi River are not of as good a quality as those of the Illinois River before the Illinois River may have found access to the same, because my study of the Illinois River leads me to consider that the sewage as a factor has been practically eliminated from the Illinois River before it empties into the Mississippi River, at Grafton, I am of the opinion that the 11078 Mississippi River at the intake tower of the St. Louis water works at the chain of rocks is not less valuable for drinking purposes and it is not more liable to carry water born diseases such as typhoid fever and cholera now than it was before the sewage of the sanitary district was run into it.

Q. State whether or not an increase in the speed of the current in the Illinois River, by reason of an added volume of water in the drainage canal would affect the amount of sedimentation that might occur in the Illinois River, and if it does affect it how and in what manner?

A. The volume of water in the Illinois River being increased by water received from Lake Michigan and the speed of the current thereby increased, the sediment being more widely distributed, the amount of sedimentation in any given strip of the river would be diminished over that which it would be without receiving the increased volume of water through the drainage canal, carrying, as it does, the clear waters of Lake Michigan.

Q. What effect if any would the increased speed of the current in the Illinois River have upon the time within which sewage from Joliet, Peoria and other towns on the Illinois River, have if emptied into the waters of the Mississippi, if the same are so removed as compared with the conditions which existed at the time it might have taken before the added volume of water from the drainage canal was put into the water of the Illinois, taking into consideration all that you know about the conditions that obtain in the Illinois River?

A. In my opinion the increase in the speed of the current in the Illinois River would have an effect to remove the sewage from Joliet, Peoria and other towns on the Illinois River, further down the stream, towards the waters of the Mississippi River and this as compared with conditions which existed before this volume of water was added to the river would be to cause sewage to extend over wider reaches of the river.

Q. If water is made more clear and less turbid than it was before, by an added volume of water being placed therein, will such bacteria as typhoid have more or less tendency to go down to the bottom of the stream than they had prior to the water being rendered less turbid?

A. It being my opinion as already stated in evidence that the solid particles carried in the stream are an important agency in effecting the precipitation of the bacteria, it would follow that water being made more clear and less turbid than it was before by the addition of a volume of clear water being placed therein, the bacilli of any form, that of typhoid fever among them, would have a less tendency to be precipitated to the bottom of the stream than they had prior to the water being rendered less turbid.

Q. If an increased volume of water in the Illinois by the addition of the waters of the drainage canal would make an increased speed in the current of the Illinois River, would that increase in the said current have any effect in increasing or diminishing the typhoid and other water born diseases on the part of the inhabitants of the state of Missouri using the waters of the Mississippi River for drinking purposes, below the mouth of the Illinois River?

A. If the volume of water in the Illinois be increased by the addition of pure lake Michigan water to the drainage canal, and the speed of the current of the river thus be increased, such increase in said current, in my opinion, would not have
11081 any effect on increasing or diminishing the liability to typhoid and other water born diseases on the part of the inhabitants of the State of Missouri using the waters of the Mississippi for drinking purposes, below the mouth of the Illinois River; and for this reason, in my opinion, from all studies of the river, from an inspection of the same, and from a study of the analytical data available, both chemical and bacteriological, from a knowledge of the death rate of typhoid fever in the Illinois River, and the rate of flow of the same, of the chemical and bacterial processes operative in the river, tending to its self purification, all sewagic matter as such has been essentially changed and the Illinois River becomes self-purified at Grafton or before reaching Grafton, and the sewagic bacteria have been removed from the water before that point has been reached, the river becoming comparable with the rivers in that section of the state tributary to the same, and thus the bacterial life having been removed, typhoid and other water-borne diseases could not affect the inhabitants of the State of Missouri using the waters of the Mississippi River for drinking purposes below the mouth of the Illinois River.

Q. Assuming that the number of bacilli coli communis in
11082 the waters of the Illinois River at Grafton are at intervals no larger than the number contained in it before the opening of the drainage canal, do you consider for that reason that the water is at all times no more dangerous than formerly?

A. From such studies as I have been able to make of the river noting the data at different intervals so far as they have been submitted to me by the Streams Examination and by witnesses for the defense, I am of the opinion that the water is at all times no more dangerous than it was before the waters from the drainage canal found access to same.

Q. Professor Sedgwick, in answer to the following question: "Assuming that the germs of typhoid fever coming from

the sewers of Chicago and passing by way of the drainage canal to Lake Peoria might be in large numbers deposited in the bed of Lake Peoria for a period of a month say, do you consider that typhoid germs would be entirely destroyed at the end of that time, in that deposit?" answered "No. sir." What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago, by way of the drainage canal to Lake Peoria and be deposited there in the bed of Lake Peoria for a period of a month, and as to whether or not typhoid
11083 germs coming from the drainage canal, under conditions as they exist today, would live for a period of a month and not be destroyed before the end of that period?

A. In regard to the assumption that typhoid germs could pass from the sewers of Chicago, by way of the drainage canal to Lake Peoria and be deposited there in the bed of Lake Peoria for a period of a month it is my opinion from my study regarding the purification of the stream, basing that knowledge upon the analytical data submitted as evidence in this case, which data indicate the removal of sewagic bacteria be-
11084 fore Lake Peoria is reached, it would follow that the typhoid germ from the sewers of Chicago, by way of the drainage canal, do not reach as far as Peoria, and in further support of this view we have the direct evidence secured by the results of the experiment upon the duration of life of the typhoid fever germ showing that in the waters of the Illinois river it does not live for a period of more than three or four days. I am of the opinion, therefore, that the typhoid germ could not pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited there for a period of a month. And further, experimental data alluded to above indicate that the conditions as they exist today are hostile to the life of the typhoid germ and therefore they would be destroyed before reaching Lake Peoria.

Q. Professor Sedgwick, in answer to the question: "Assuming that typhoid fever germs coming from Chicago sewers are deposited in large numbers in the lakes and slack water portions of the Illinois River above Peoria, do you or do you not consider that flood conditions such as would scour the deposits

from the beds of the streams would cause the water leaving Lake Peoria to contain at times more infectious and dan-
11085 gerous pollution than is at present in the diluted sewage entering at the Bear Trap Dam at the foot of the drainage canal?" stated "I think at times it might." What is your opinion, taking into consideration all that you know about the conditions of the drainage canal, the Desplaines River and the Illinois River as a sanitary expert as to whether such conditions at times might exist?

11086 A. From all the knowledge which I have been able to obtain about the conditions in the drainage canal, the Desplaines River and the Illinois River, the same being based upon personal inspection and analyses, both chemical and bacteriological, already submitted in evidence in this case, from the bacterial purification of the river, as shown by such tables which obtain at Lake Peoria, and especially from the positive results we have in the experiments of Doctors Zeit, Jordan and Russell upon the viability of the typhoid germ in the sewage-laden waters of the Illinois River, the results of such experiments being to show that the typhoid germ lives for a short time in the water of this river, the period being represented by three or four days, it is my opinion that the typhoid fever germs coming from the Chicago sewers would not reach down the Illinois River as far as Peoria, and further, even if such bacteria may be deposited in the sediment of the stream in the course of its passing down the river, the fact that the same has been taken up from the sediment of the river and been subjected to the destructive agencies of the stream, I am further
11087 fortified in the opinion that the typhoid bacillus would not reach as far as Lake Peoria and therefore water leaving Lake Peoria could not possibly contain more infectious and dangerous pollution that are at present in the diluted sewage entering the Bear Trap Dam at the foot of the drainage canal.

Q. What is your opinion as to whether typhoid fever germs coming from the sewage of Chicago are deposited in large numbers in the lakes and slack water portions of the Illinois River above Lake Peoria?

A. From all data available concerning the character of the water in the Illinois River, the agencies at work in the river affecting chemical and bacterial changes, all evidence showing a bacterial purification of the river at Lake Peoria, and added to this the positive results from experiments instituted and carried out by Dr. Zeit, Dr. Jordan and Dr. Russell, I am very clearly of the opinion that typhoid fever germs coming from Chicago sewers do not reach the lakes and slack water portions of the Illinois River above Peoria.

Q. What is your opinion, based upon all the knowledge which you have of conditions at Lake Peoria, as a chemist, bacteriologist and sanitary expert as to whether at any time,
under any conditions, the number of typhoid bacilli at
11088 that point is even as great as it is at the Bear Trap Dam
at the end of the drainage canal?

A. It is my opinion that by no possibility and under no conditions of the river can the number of typhoid fever germs at any point be as great as they are at the Bear Trap dam at the end of the drainage canal.

Q. Do you know of any evidence scientifically secured or otherwise that shows that accumulations of typhoid germs are found in lakes or slack water basins of rivers and remain there in storage in vast numbers for any considerable period of time in a virulent state and are suddenly flushed out by freshets so that great numbers of typhoid fever germs are present, flowing in a stream a considerable distance from the source of pollution in greater quantities than exist at the source of pollution?

A. I know of no evidence scientifically secured which shows that such accumulations of typhoid fever do occur in the slack waters and basins of any river so that greater numbers of typhoid fever germs are ever found floating in a stream within a considerable distance from the source of pollution, and certainly not in greater quantities than they exist at the source of pollution.

11089 A. Assuming that no other pollution or infectious matter or infection enters the river, save that which it receives from the sanitary district of Chicago, from your knowledge as a chemist, bacteriologist and sanitary expert, have you had any personal experience or knowledge which would lead you to believe that the water of the Illinois River at Grafton is infected with the sewage from Chicago, and if said water enters the Mississippi River, becoming mixed with the latter water, would it be a menace to the inhabitants of the Missouri shore of the Mississippi River using the Mississippi River water for drinking purposes, at points below on the Missouri shore?

A. Assuming no other pollution or infection, I have no knowledge which would lead me to believe that the water of the Illinois River at Grafton is infected with the sewage of Chicago and therefore if the said water emptied into the Mississippi River and mixed with the water, it would not become a menace to the health of the inhabitants of the Missouri shore of the Mississippi River for drinking and domestic purposes.

Q. Is there anything, based upon your knowledge as a chemist, bacteriologist and sanitary expert which would lead you to believe that the waters coming from the Illinois 11090 River at Grafton were infected by the sewage of Chicago?

A. I have not, basing my knowledge as a chemist and sanitary expert upon all data which I have been able to gather and from personal knowledge of the course and habit of the stream which would lead me to believe that the water coming from the Illinois River at Grafton was infected with the sewage from Chicago, but on the contrary I believe that the process of natural purification which obtains in this stream, the dilution the sedimentation, the bacterial and chemical changes, the germicidal effect of the waters upon bacteria carried by the same its rate of flow, all contribute to practically purify the waters of the River at Grafton from sewage which may enter at Chicago.

Q. Assuming that the water of the Illinois River mixed with the waters of the Mississippi river at Grafton and subsequently mixed with the waters of the Mississippi River at its mouth, do you consider the waters of the Illinois River thus comingled with the waters of the Mississippi River and the Missouri River a menace to the health of the inhabitants of Missouri living upon the Mississippi River, using the Mississippi River water for drinking purposes at points on the Missouri shore?

A. From my knowledge of the quality of the water as it

issues from the mouth of the Illinois River at Grafton,
11091 before the same becomes mingled with the waters of the
Mississippi, in my judgment being better in quality than either the Mississippi River as it flows by at Grafton or than the Missouri River as it empties below, I am clearly of the opinion that the water of the Illinois River, thus comingled with the waters of the Mississippi and Missouri Rivers is not a menace to the health of the inhabitants of Missouri living upon the Mississippi River using Mississippi River water for drinking purposes at points on the Missouri shore.

Q. Is there any evidence to be secured, chemical, bacterial or otherwise, in your opinion, that can establish the conclusion that the waters of the Illinois River at Grafton are infected by the sewage from Chicago, eliminating all other sources of infection?

A. In view of the extent, quality and kind of investigations bacteriologically, chemically and otherwise that have been made in this case being so extensive and exhaustive as they are, it is my opinion that there is no evidence which could establish the conclusion clearly and decidedly that the waters
11092 of the Illinois River at Grafton are infected with sewage
from Chicago.

Q. Now, assuming that the only pollution upon the water shed of the Mississippi and its tributaries above the intake of the St. Louis water works was that derived from the sanitary district of Chicago, and having in mind the large amount of typhoid fever in Chicago, do you or do you not believe that infected and dangerous pollution might, under existing conditions find its way into the water supply of the city of St. Louis?

A. The evidence as already introduced in this case, both chemically and bacteriologically showing, in my opinion, so conclusively that the agencies of self-purification operative in this stream have practically transformed sewagic matters from the city of Chicago before they reach Grafton, reducing the river at that point practically to the condition of the streams tributary to the same, and the positive results secured from the experiments of Doctors Zeit, Jordan and Russell, upon the viability of the typhoid fever in the polluted waters of this stream, I do not believe that infections and dangerous pollution might under existing conditions find its way into the water supply of St. Louis.

11093 Q. Assumming that there was no typhoid fever pollution of the waters upon the water shed of the Mississippi and its tributaries above the intake of the St. Louis water works other than that derived from the sanitary district of Chicago, do you or do you not believe that typhoid fever germs from said district are liable to find their way into the water works of the city of St. Louis through the intake at the chain of rocks?

A. Eliminating all possibility of typhoid fever infection or other pollution of the waters of the water shed of the Mississippi River above the intake of the St. Louis water works other than that derived from the sanitary district of Chicago, in view of all evidence at hand regarding the quality of the Illinois River at Grafton, the bacterial and chemical agencies at work tending to self-purification of the stream, and the positive evidence upon the viability of the typhoid germ as proved by the experiments of Doctors Zeit, Jordan and Russell already a matter of evidence in this case, I do not believe that typhoid fever from the sanitary district can find its way to the water supply of the city of St. Louis through the intake at the chain of rocks.

Q. Professor Sedgwick, in answer to the question just 11094 propounded to you, stated: "I believe they are liable to find their way into the intake" and when asked why, answered "for the reason that typhoid fever having been frequently very abundant in the city of Chicago, I must start with the assumption that a very large number of typhoid germs find their way into the sewage of the city, pass through the sewers and on into the sanitary canal, and subject to local conditions may, in diminishing numbers, pass out of the Illinois River, mingle with the waters of the Mississippi River and pass over to the other side and find their way into the intake at the chain of rocks." I want to ask you do you know of any evidence, based upon any analyses, experiments or otherwise that justifies the assumption that typhoid fever germs will pass through the sewers and on into the drainage canal and subject to local conditions may, in diminishing numbers, pass out of the Illinois River, mingle with the waters of the Mississippi and pass over to the other side and find their way into the intake at the chain of rocks of the St. Louis water supply?

A. In answer to that question I would say that I know of no evidence to support the assumption thus made, but upon the contrary the analytical data and the results of the ex-
11095 periment which has been carried out decidedly indicate that in the Illinois River the assumption is unwarranted, all evidence both bacteriological and chemical pointing to the bacterial purification of the river at Averyville, a marked chemical purification of the same at that point and completed at Grafton, and the positive evidence which we have from the experiments carried out by Doctors Zeit, Jordan and Russell upon the viability of the typhoid bacillus in the waters of this River, showing that the duration of life is of a short period in this sewage-laden stream in its upper reaches, the same not extending for more than a period of three or four days, and rate of flow of the river being largely in excess of this period. the typhoid fever germs in my opinion can not pass from Chicago through its sewers, out into the drainage canal, thence into the Illinois River, thence into the Mississippi River and across the same and enter the intake tower at the chain of rocks at St. Louis.

Q. Assuming that an epidemic of Asiatic cholera should break out in the city of Chicago, is it possible that the germs of that disease might find their way into the intake tower at the St. Louis water works at the chain of rocks, from the city of Chicago.

A. It is my opinion that in the event of an outbreak of cholera in the city of Chicago, the germs of that disease
11096 could not find their way into the intake tower at the chain of rocks of the St. Louis water works from the city of Chicago, for the reason the bacterial agencies at work, operative in the purification of the stream effect a bacterial purification of the Chicago river before Averyville is reached. Regarding the cholera germ, from such knowledge as I have been able to gather concerning it, it is less resistant than the typhoid fever germ and therefore any agency operating to the removal of the typhoid fever germ would, in my opinion, be more decided than in the case of the typhoid fever germ.

Q. Considering your personal knowledge as a sanitary expert of typhoid fever conditions in the sanitary district of Chicago, and existing conditions in said district as to sewers and outfalls there and of the amount of sewage and all the existing conditions of the Desplaines, Illinois and Mississippi and Missouri Rivers, and all the conditions existing upon the water sheds of said streams and the tributaries thereof, and all existing conditions as to the water supply of the City of St. Louis and the general sanitary conditions existing in the City of St. Louis, would you or would you not beyond a reasonable doubt attribute the principal portion of the increase of typhoid fever in St. Louis, assuming there has been an increase in St.
11097 Louis, since the opening of the drainage canal, to the infected sewage of the sanitary district of Chicago?

A. For reasons which have been given repeatedly in this examination, conditions which obtain in the river from the self-purification of the same, all of which in my opinion contribute to the practical removal of all sewage as such from the river at Grafton, I should not attribute, beyond any reasonable doubt the principal portion of the increase of typhoid fever in St. Louis to the infected sewage of the sanitary district of Chicago.

Q. Professor, do you consider that the Illinois river water containing the mixed sewage and canal water from the Chicago Sanitary District, since the opening of the drainage canal, has rendered less safe and wholesome now than before the opening of the canal for drinking purposes on the part of the inhabitants of the State of Missouri, the waters of the Mississippi river below the mouth of the Illinois river?

A. From the conditions of the river, the agencies operative in the self-purification of the stream, which in my opinion have practically transformed all sewage entering the river from the drainage canal when the river reaches Grafton,
11098 it is my opinion that the drainage canal has not rendered less safe and wholesome the water used for drinking purposes on the part of the inhabitants of St. Louis, using the waters of the Mississippi river below the mouth of the Illinois river than they were before the canal was opened.

Q. Professor Sedgwick, in answer to a question among other things answered: "The mere presence of pollution, I mean by that uninfected sewage, that is, supposing Chicago reduced her typhoid death rate and would still put her sewage down there, that sewage as affecting the longevity or growth of germs that get in from Peoria or elsewhere would be an added menace to cities with water supply, even if she did not send typhoid fever germs down, sending the filth alone is serious." I will ask you what is your opinion based upon a bacteriological, chemical and sanitary experience as to whether the sewage from Chicago favors the longevity or growth of germs from Peoria or anywhere else, emptying their sewage into the Illinois river?

11099 A. From the evidence already given in this case and particularly the positive results of the experiment by Doctors Zeit, Jordan and Russell, in which they have demonstrated that the typhoid germs from the City of Chicago can live but a short period in this sewage laden water, such period covering, according to those observations perhaps three or four days, it is my opinion that the sewage of Chicago does not favor the longevity or growth of germs from Peoria or any other city also emptying its sewage into the river, but on the contrary the same agencies which have operated in this river, which have tended to diminish the viability of typhoid fever would still be operative upon typhoid fever germs coming from points below.

Q. Does the presence of sewage in water add to the longevity or growth of germs?

A. From all knowledge I have been able to gather by study upon this question, and from the study of the experiments, by Drs. Zeit, Jordan and Russell, it is my opinion that the presence of sewage in water tends to diminish the viability of the typhoid bacillus.

11100 Q. Do you consider that the Illinois river water polluted and infected by the sewage from the Chicago drainage district, since the opening of the drainage canal, has rendered less safe waters or water supply of the City of St. Louis as drawn at the intake tower, chain of rocks, at the City of St. Louis?

A. It is my opinion that the Illinois river polluted and infected from the sewage of Chicago Sanitary District, subject as it is to the purifying agencies operative in this stream, tending to transform the same, which according to data is practically complete at Grafton, it has therefore not rendered less safe the water supply of the City of St. Louis as drawn at the intake tower chain of rocks.

Q. Assuming that the Chicago sewage from five million people living in the sanitary district of the City of Chicago, should be discharged into the Chicago drainage canal and carried through the canal into the Desplaines river and thence into the Illinois River, Chicago being situated 357 miles from the St. Louis intake, and assume that a typhoid epidemic of extraordinary proportions should become prevalent among the residents of the sanitary district and at a time when the sewage from said district is being discharged in the canal, what immediate and pending danger would exist and what effect would it have on the people of St. Louis and those people living on the Missouri side of the Mississippi river below Grafton
11101 who use the water of the Mississippi river for drinking purposes?

A. Assuming that the population of Chicago should increase even to the population of five million and the sewage should be discharged into the drainage canal and be carried through the drainage canal to the Illinois river and so pass down the river to the Mississippi river, in my opinion the bacterial or the germicidal effects of the water would still be operative and operative in a degree as efficient as they are at present, and inasmuch as the action of the water bacteriologically and chemically and otherwise, according to the experiments already introduced in this evidence now destroys the typhoid bacillus at a period not exceeding three or four days, in my opinion it would follow that the causes operative in the river would even with a population of five million and with a typhoid fever epidemic obtain so that the sewage from the sanitary district, discharged into the canal would not be an immediate and impending danger upon the people of St. Louis and people living on the Missouri side of the Mississippi river using the water of the Mississippi river for drinking purposes.

Q. Taking into consideration all the knowledge which you possess in regard to the chemical, bacterial and physical conditions of the waters of the Illinois river and its tribu-
11102 taries and the river itself and the different towns sewering into the Illinois river and its tributaries, the population upon the watershed of the Illinois river, both rural and

urban, the discharge of the river under all conditions and during all seasons, what is your opinion as to the effect of flowing the sewage from Chicago through the drainage canal into the Desplaines and Illinois rivers, upon the inhabitants of the State of Missouri, using the waters of the Mississippi river for drinking and domestic purposes?

A. Taking into consideration all the knowledge which I possess regarding the chemical, bacterial and physical conditions of the waters of the Illinois river and its tributaries, such knowledge being secured from an inspection of the same, from the mouth of the Chicago river and the drainage canal, and the river to its mouth at Grafton, in view of all the data available from every source, I am very clearly of the opinion that the effect of flowing the sewage of Chicago through the drainage canal and the Desplaines and Illinois rivers does not militate against the healthfulness of the inhabitants of the State of Missouri using the water of the Mississippi river for drinking and domestic purposes.

11103 Q. Taking into consideration all the assumptions assumed in the last foregoing hypothetical question, and taking into consideration all the typhoid statistics as they obtain along the watershed of the Missouri, Mississippi and the Illinois river, in the City of Chicago and in the City of St. Louis, and assuming that there is an increase of typhoid fever cases in the City of St. Louis since January, 1900, and taking into consideration all chemical, bacterial and other knowledge which you possess, what is your opinion as to whether the increase in typhoid fever, assuming that there has been an increase as above indicated, in the City of St. Louis since the opening of the drainage canal can be attributed to the opening of the drainage canal, as the direct, immediate and approximate cause of said increase beyond all reasonable doubt?

A. From such study as I have given to the conditions stated in the assumption and your question, from my knowledge of the habits of the Mississippi river, it being in my judgment a water unfit to use in its raw state for public water supply, in view of the fact that the pollution existing from the Missouri river, a matter as evidence already given in this case, from my knowledge of the conditions which obtain upon the drainage canal and the Desplaines river and the Illinois river and the agencies of self-purification operative in this stream, 11104 all of these combined tending to effect a practical bacterial purification of the Illinois river at Averyville, I am of the opinion that any increase in typhoid fever, if there has been any increase of typhoid fever since the opening of the drainage canal, can not be attributed beyond all reasonable doubt to the opening of the drainage canal as its direct, immediate and approximate cause.

Q. Assuming that there is an increase in the typhoid conditions in St. Louis over normal conditions due to its water supply, where in your opinion should a sanitarian, studying the question, look for the causes of the infection?

A. For reasons which have been stated repeatedly in this examination, from the knowledge of the Illinois river itself, its surroundings and the chemical and bacterial changes operative tending to the self-purification of the stream, and from the positive evidence of Doctors Zeit, Jordan and Russell, proving that the typhoid bacilli from the City of Chicago, passing through the drainage canal and out in the Illinois river, can not exist in that river for a period extending more than three days or four days, it is my opinion that the typhoid bacillus 11105 from the City of Chicago can not find its way to the intake tower at the chain of rocks, and the intake of the waterworks of St. Louis in the Mississippi river, and therefore the causes for such an increase in typhoid fever must be looked for at points nearer the intake tower than from the sanitary district of Chicago.

Adjourned until 10:30 a. m., Wednesday, March 2, 1904.

10:00 A. M., Wednesday, March 2, 1904.

11106 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. E. G. SMITH

resumed the stand for cross-examination by Mr. Jeffries, and testified as follows:

Q. Professor, if the urine and excreta of a typhoid patient is discharged into 60 gallons of distilled water, will the typhooid fever germs live longer in such condition than if discharged into 197 gallons of distilled water?

A. From my study of the longevity of typhoid fever germs, and from knowledge I have been able to obtain, the general principle is clear that an increased dilution of water tends to increase the longevity of the micro-organism. The conditions of the question could only be answered by applying the general principle that the more dilute the sewage the greater the tendency to longevity of the organism.

Q. Then they would have a tendency to live longer in the larger quantity of water than in the smaller?

11107 A. Applying the above principal it is my opinion that they would.

Q. Professor, assuming that there is a population of 1,545,300 people, the sewage discharged from said population passing into the Chicago drainage canal, and assuming that there are from 700 to 900 deaths per annum from typhoid fever among the population of the territory sewered into the canal and that the urine and fecal matter of that population is daily discharged into 304,686,455 gallons of water, would the typhoid fever germs thus deposited in that quantity of water be of shorter or longer longevity than if deposited in 92 718,000 gallons of water daily?

A. Applying the principle as stated in my first answer it would be my opinion that there might possibly be a tendency to a slight prolongation of the life of the micro-organism.

Q. Would not the natural tendency be to prolong the life of the germ under such circumstances?

A. I think it would a little, but assuming the conditions given, the deposit of fecal matters, of sewagic matters from that population in such waters, the amounts of which are indicated in the question in either case, we would be dealing with 11108 a sewage water which sewage water experiments have shown to be inimical to any prolonged life of the typhoid bacillus.

Q. Professor, were you acquainted with the Chicago River prior to 1900?

A. Yes sir. I have lived in Beloit, Wisconsin, and frequently have been here and observed it in going to and from.

Q. Will you state its condition as you saw it and observed it, generally speaking?

A. Generally speaking it was an exceedingly foul, offensive stream, offensive to sight and to the nostrils. It was more or less turbid, often with a scum floating upon the surface, of a dark color and without very much apparent current.

Q. As compared to conditions that exist in the Chicago River prior to the opening of the canal, in your opinion will pathogenic bacteria discharged into the Chicago River have greater longevity since the opening of the canal and the passage daily of 250,000 cubic feet of water per minute through the Chicago River than they had in the Chicago River prior to the opening of the canal?

A. The influence of dilution by the lake water, tends to
dilute sewagic matters placed in the river, and in so
11109 far tends to prolongation of the life of the bacteria, yet the
river today is decidedly of sewagic character so that in my
opinion the longevity of the typhoid organism would not be very markedly different before the introduction of the quantities of lake water and conditions as we now find them; and in addition to that there is another factor, the river as I formerly knew it and had observed it was quiet, with very little current, and today there is a decided current tending to cause such organisms to pass out of the Chicago River in short periods.

Q. Assuming, Professor, that pathogenic bacteria from Joliet passed down the Illinois River as it existed prior to the opening of the canal, what effect has the addition of 250,000 cubic feet of water per minute into the Illinois River upon the passage of the pathogenic bacteria from Joliet down the Illinois River?

A. The introduction of this large amount of water would tend to increase the speed of the current and therefore tend to push pathogenic bacteria farther down the river than they would prior to the opening of the canal.

Q. Assuming, Professor, that the bacteria counts at
11110 Joliet caused by sewage pollution were much greater
prior to the opening of the canal than they have been
since the opening of the canal, what effect would the discharge of 250,000 cubic feet of water per minute into the river above

Joliet have upon the longevity of the pathogenic germs discharged into the river at Joliet, the waters so discharged not having as great a number of bacterial counts as the water in the river at Joliet prior to such discharge.

A. The waters at Joliet after the addition of the water from Lake Michigan, of waters introduced under the conditions of your question, being yet of a decided sewagic character, and pathogenic germs found therein being subject to the germicidal effect of such sewagic waters, it would be my opinion that this dilution of the water at that point might possibly prolong it, but that it would destroy them in short periods, and the typhoid bacillus would, under these conditions, be subject to the germicidal effect of the diluted sewage.

Q. It is your opinion then that the longevity of the typhoid germ would not be prolonged under the latter conditions over their longevity under former conditions? 11111

A. It would be difficult to make a positive answer to that, but it is clearly my opinion that the pathogenic germs would not be materially increased by such dilution.

Q. Assume, Professor, that the volume of water from Lake Michigan was increased from 250,000 cubic feet per minute to 500,000 cubic feet per minute, with the same amount of sewage discharged into the Chicago River and the drainage canal what effect would such added volume of water have upon the longevity of pathogenic bacteria?

A. It might possibly prolong the life a little, but with 500,000 cubic feet of water pathogenic germs entering the river at Joliet would still be subject to the germicidal action of sewage waters.

Q. It would, however, have an effect to increase the longevity of the germ?

A. Possibly slightly as it is known that this germ will live longer in waters than in sewage, and concentration of sewage affects the life of the germ, but the exact difference would be a matter which could only be determined by actual experiment. 11112

Q. And the longevity of the germ in each instance would depend upon the inherent virility of each pathogenic germ?

A. It is true that different strains, as they are termed of typhoid fever organisms, possess a different degree of resistance to destructive agencies.

Q. From your own personal experience and observations, how long will a typhoid germ live in sewage?

A. I have never carried out observations upon the duration of the life of the typhoid germ in sewage.

Q. And this experiment or observation has never been personally made by you, either in the laboratory experiments or otherwise?

A. No, it has not.

Q. Has such an observation or experiment been made in your laboratory, under your direction and supervision, in sewage?

A. An observation of a study of the vitality of the typhoid bacillus in sewage waters has not been made in my laboratory under my direction.

Q. What, in your opinion constitute, in the main, the environments which affect the longevity of the typhoid
11113 germ after it leaves the human body?

A. There are several elements entering into the longevity of the typhoid germ after it leaves the human body; the matter of temperature, of moisture, the relation to other bacteria, whether these bacteria may be in soil or in sediment of the streams or in running water. I consider those as three of the important factors in the consideration of the environment to which it is subjected.

Q. Professor, assuming that at Joliet there is a daily flow of 271,424 cubic feet of water per minute and that in that water there are 70,000 bacteria per cc., as shown by the bacterial counts upon the plates from the samples of water taken at that point, what effect would the removal or withdrawal of 232,131 cubic feet of water per minute have upon the longevity of pathogenic bacteria contained in that water in the event such bacteria was so contained therein?

A. The removal of 232,000 cubic feet per minute from 271,000 cubic feet per minute would reduce the flow of the river to about 40,000 feet per minute. This would, therefore, tend to concentrate those organisms so that there would be a greater toxic effect from the organism due to concentration of the toxins in the same.

11114 Q. And such concentration would have the effect of shortening the life of the pathogenic bacteria?

A. The special results of the action of the organisms being that of the destruction of the pathogenic bacteria from the toxins eliminated, it would therefore follow that the concentration of toxins would tend to diminish the vitality or viability of pathogenic germs in the same.

Q. State, Professor, if from 250,000 to 500,000 cubic feet of water per minute pass through the drainage canal, the Desplaines and thence into the Illinois River would they not have the effect of more rapidly removing the sewage from the cities of La Salle, Peoria, Pekin and other cities located upon the banks of the Illinois River and carrying such sewage at a more rapid rate on down the river and also have a tendency to increase the longevity of the pathogenic germs contained in the water from the sewage of those cities?

A. The addition of this volume of water, as already a matter of evidence and opinion in this case, tending to increase the rate of flow of the stream, it would be self-evident that solid suspended particles or dissolved matters would be
11115 pushed further down the stream, because of the inflow of such river, and further, the effect of dilution might possibly tend to increase the longevity of the pathogenic germs, but the exact degree of such prolongation could only be determined by a matter of experiments.

Q. Professor, assuming that in 1892 the water in the Illinois River, immediately above the city of Peoria, contained pathogenic bacteria coming from the sewers of La Salle, Morris, Marseilles, Ottawa and Joliet, what effect has the opening of the canal and the discharge of the water from Lake Michigan through that canal had upon the typhoid fever germs that would reach the city of Peoria since the opening of the canal, coming from the cities above mentioned?

A. While it is true that the increase of the flow of the river increases the speed of the current and dilutes the water, tending on the one hand to push the sewage from these cities, somewhat further down the river, and also to dilute the same, yet from all data which I have been able to gather in this case from the experiments made, I am of the opinion that the river at Averyville, above Peoria, has undergone a practical bacterial purification. It would be impossible to say that no germs 11116 from any of these points have never or would never find their way into the river at a point above Averyville, but the data at hand upon the purification of the stream make it, in my opinion, quite certain that there are very few pathogenic germs from any point in the river at that point.

Q. Assuming, Professor, that typhoid germs from the respective cities mentioned in the preceding question, arrive in the Illinois River at a point immediately above Peoria, in a virulent condition, prior to the opening of the canal, what effect would conditions such as are brought about by the opening of the canal have upon the longevity of the typhoid germs contained in the water at Peoria under the assumption?

A. Assuming that typhoid fever germs were in Lake Peoria above the city of Peoria, in 1892, and assuming, as I understand the question to mean, that they are there at the present time, the opening of the drainage canal has not affected the deposit of typhoid fever germs at that point.

Q. What effect would the opening of the canal have upon the longevity of the typhoid fever germs finding their way into the Illinois River at a point immediately above Peoria, as stated in the hypothetical question just put?

A. Assuming that typhoid fever germs were in the river 11117 above Peoria and they are there today, it would be clear that the opening of the drainage canal has not affected the longevity of the germs at that point, assuming they came from the same points.

Q. Assume, Professor, that typhoid fever germs came from the sewers of La Salle, Marseilles, Ottawa and Joliet, prior to the opening of the drainage canal. and found their way in the Illinois River to a point immediately above the city of Peoria in a virulent condition, state whether or not in your opinion the opening of the canal has rendered conditions such that it is less liable for them to continue finding their way there subsequently to the opening of the canal than prior thereto?

A. Assuming that typhoid fever germs in a virulent condition came from the sewers of the cities mentioned and found their way in such virulent condition to the lake at a point immediately above Peoria in 1892, it is my opinion that the conditions which have obtained since the opening of the canal have been such that it would not make it less liable for them to reach that point than they did in 1892.

Q. Under the same assumption as contained in the last
11118 question are they not more liable to find their way into
the Illinois River at a point immediately above Peoria since the opening of the canal than prior thereto?

A. Assuming that in 1892 typhoid germs from the sewers at these points mentioned found their way into and were present in the waters above Peoria, the addition of the larger volume of water increasing the speed of the river and dilution of the same would tend to make them more liable to be found from the same points in the stream.

ADJOURNED UNTIL 2:00 P. M. of same day.

2:00 P. M., Wednesday, March 2, 1904.

11119 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. E. G. SMITH

resumed the stand for further cross-examination by Mr. Jeffries, and testified as follows:

Q. Professor, from your knowledge of the Illinois River is it not a fact that pathogenic and disease producing organisms so far as their facilities for longevity and virility are concerned may be more manifest in the Illinois River immediately above Peoria, since the opening of the drainage canal than prior thereto?

A. Assuming that they were there before the canal was opened, of which we have no positive evidence, it would be true, in my judgment, that the opening of the drainage canal, in-
creasing the speed of the river and the dilution of the
11120 same, would render it more liable for them to be there.

Q. With your knowledge of the Illinois River as you saw it in 1892 at Peoria, could you say that there were no typhoid or other pathogenic bacteria in the water of that river at a point immediately above the city of Peoria, when you observed it?

A. In reply to that question I would say that I have no evidence that there were any pathogenic bacteria there at any time.

Q. Is it not a fact that the same conditions would maintain throughout the entire length of the Illinois River since the opening of the drainage canal as compared to conditions existing prior thereto, as stated in the second preceding question and answer, with reference to conditions at a point immediately above the city of Peoria?

A. It is my opinion that the same conditions would not necessarily obtain throughout the whole length of the river, for the reason that there is in the stream a seasonal variation, in the river at its low period the current being greatly accelerated, and in periods of high water the water not being raised in such proportion or the current therefore increased.
11121 Further, as we descend the river the river continues to receive the inflow from other streams thereby increasing the amount of water, and therefore it would follow that the drainage canal would continue to exert a diminishing influence as we pass down the stream, upon the speed of the river, thus tending to affect the effects of dilution and increased speed of the current, so that it would not obtain throughout the whole length of the river the same as before.

Q. Professor, if advised that prior to the opening of the drainage canal, during a greater period of the year, the Illinois River, for miles above the several dams, was in a quiescent condition, so much so that green scum formed upon its surface, that in rowing in a skiff the skiff would leave behind it a line observable to a great distance, that when blocks of wood were thrown into the river their movements would depend upon the direction of the wind, that since the opening of the canal there has been at all times a continuous current both above and below the several dams, and the green scum formation has not appeared to any great extent, what effect would this change in the

velocity of the stream and the physical conditions of the
11122 stream have upon pathogenic bacteria in waters of that
stream, assuming that they had been discharged into it?

A. The effect of establishing of a current assuming they were there must manifestly be to push them somewhat further down the stream.

Q. Would it not also have the effect of increasing their longevity, vitality and virulence?

A. It would increase their logevity only so far as they might have been pushed further in the short distance which they might have advanced, owing to the increased speed of the current further, in my judgment it would not affect the virulence of the germ.

Q. What would be the difference in the element of sedimentation as contained in the last preceding hypothetical question?

A. In the increase in the speed of the current of a river
or stream, the speed of the current alone being brought into
consideration, the rate of sedimentation would be
11123 diminished. On the other hand if the speed of this cur-
rent be due to an increased volume of water admitted
from Lake Michigan, after the opening of the drainage canal, there would be decided compensation in the loss from sedimentation from the rate of the stream owing to the added area of the waters spreading out over the bottoms by the low shelving banks in the course of the stream so that in my judgment there would not be any very great difference between the total sedimentation in the stream before and after the opening of the drainage canal.

Q. As applied to the conditions of the water in the bed of the stream immediately above and below the dams in question, how would sedimentation be affected by the increased flow?

A. In the bed of the stream the increase of the flow of the current would tend to diminish the rate of sedimentation.

Q. Professor, in your direct testimony you stated that you made an observation of the water in the Illinois River at Peoria in 1892, by being upon it in a boat and went out to and across the wagon bridge, observing the river from time to time that it was of a dirty appearance, as you call it, and possessed in warm seasons of a decidedly disagreeable odor, and that in your opinion it was unfit for use as a water supply.

11124 Please state your opinion as to the cause of this disagreeable odor and dirty appearance of the water which you observed?

A. The cause of the appearance of the water at that time and its unsatisfactory qualities for a water supply was due to the materials in the stream.

Q. What in your opinion was the character of the materials that had been discharged into that stream, producing the effects in question?

A. I did not make any special investigations at that time, as I was simply asked to pass upon it as a desirable or an undesirable supply to pump into the city of Peoria, and I considered it unfit for use and advised the Peoria Water Company not to use the water, and further not to even lay an intake to the river as an emergency supply. I do not know whether that was carried out or not, but the matter was talked over. The water at that time, from its appearance and the analytical data which, as I recall them now, would not justify me as an adviser to the company to recommend their introduction into the public supply in the raw condition.

Q. It was your opinion that the water at that point, at that time, contained substances injurious and harmful to health?

A. It was my opinion at that time that the water was

11125 unsuited for a public water supply, the chemical analysis showing a considerable amount of organic matter contained in the same, and there being some suspended matter, and the waters having some odor and therefore the water was not fit for use in its raw condition.

Q. Now, Professor, if typhoid fever germs had been deposited in the water of the Illinois River at that point, at that time, 1892, what can you say as to the extent of their longevity as compared with typhoid fever germs of the same strength and virulence deposited in the river at that point today, since the opening of the drainage canal?

A. It would be my opinion from the conditions noted in the light of knowledge obtained regarding the action of saprophytic bacteria since that time, that the tendency would be to destroy the typhoid and pathogenic bacteria rapidly at that time, as they would have been subjected to the germicidal effects of the water.

Regarding the effect of the water upon the typhoid germ since the opening of the drainage canal, it is my opinion as has been repeatedly stated in the course of this evidence that the same are eliminated practically at this point, such state-
11126 ment being based upon data, analyses and positive experiments already a matter of record in this case.

Q. From your personal observation of the waters of the Illinois River at a point immediately above the city of Peoria, in 1892, as compared with your personal observation of the water of the Illinois River at the same point in September, 1903, is it not a fact that elements destructive of pathogenic bacteria were more prevalent, apparent and abundant in 1892 than in September, 1903?

A. The waters when I was there in September of this last year 1903, were roily, owing to the recent storms, and so far as personal observation shows therefore I could hardly draw a comparison between the two conditions, there being a large amount of dirt and silt in the river at that time. It could not be based upon any personal observation.

Q. Taking into consideration your personal knowledge of the Illinois River, during the year 1892, and the year 1903, what would you say?

A. From my knowledge of the river and from data and all knowledge which I have been able to gather from the
11127 Illinois River and its characteristics it is my opinion that the agencies tending to destroy bacteria were ample in 1903, and I believe they were as ample to affect the changes in 1892. The current may have been more sluggish at this particular time, but in my opinion the agencies were as effective now as they were then, removing as I believe they do practically the pathogenic bacteria from the stream now.

Q. But were not those agencies of destruction more abundant and more prevalent in the waters of the Illinois River at that point in 1892 than in 1903?

A. That question could hardly be answered positively. They were decided at that time and they are very decided now.

The condition of the stream at that time tended to remove these organisms and it would be difficult to institute a comparison regarding the germicidal effect of the water, dirt and material which might impart an odor to a water need not necessarily be germicidal in its effect. It may be due to the destruction of algae which might impart an odor to the water and yet not be harmful to the same, and yet render it unsatisfactory for use. Some inquiry was made in 1892 as to the source of the disagreeable conditions of the water and its unfitness for the public water supply. 11128

Q. But is it not a fact, Professor, that the saprophytic influence over the pathogenic bacteria per cc. of water was greater in 1892 than in 1903, in the Illinois River immediately above Peoria?

A. That is a difficult question to answer. I do not think I could answer that question off hand.

Q. Is it not a fact that water which emits a disagreeable odor and which has a dirty appearance caused by the discharge of waste and refuse matter into that water contain greater quantities of saprophytic material and agencies for the destruction of pathogenic bacteria than water which emits no disagreeable odor and which has no bad physical appearance?

A. I think as a general proposition that would be true.

Q. And the life of a typhoid fever germ would be shorter when deposited in a water which emits the disagreeable odor and contains the substances thus spoken of in the preceding question than it would be in the water which emits no disagreeable odor and contains but small quantities of such substances?

A. It would be true that water which contains an abundance of saprophytic life would tend to the formation of large amount of the toxins which would prove destructive to bacteria placed therein. 11129

Q. Professor, in passing judgment as a sanitarian upon the condition of water in a running stream, is it not a fact that the population residing upon the water shed of that stream is one of the principle and material elements entering into a consideration of the condition of the water?

A. The population is one of the important factors in passing upon the desirability of a stream for public use.

Q. Is it possible to give an opinion as to the sanitary condition of the water in a running stream for drinking and domestic purposes from a consideration of the bacterial and chemical conditions of the water alone, eliminating therefrom the population residing upon the water shed and all sources of pollution above the point where the water is being observed?

A. Well, that is a very difficult question to answer; opinions might vary. As I stated in the direct examination I believe that a sanitarian should take into consideration everything possible which will help him to interpret the stream, its sources, 11130 its pollution, the changes which it undergoes, in order to give a full opinion of the character and suitability of the same for public use. However, I believe that chemical and bacteriological data can and often do throw light upon the quality of a water which may enable us to pass an intelligent and honest opinion upon the quality of the water and its adaptability to public supply. Almost any one who has had any extended experience of this kind is called upon to do that continuously, and we are frequently called upon to pass upon the quality of a supply from chemical and bacteriological data alone, and in my judgment they do throw very much light upon it. In the determination of the adaptability of a water and the purification of the same we appeal almost exclusively to the chemical and bacteriological data, and we pass upon the supply upon those data alone. Whenever a water is taken from a stream and filtered the adaptability and the safeness of the same, whether it can be used, is determined from the chemical and bacteriological data. It is a scientific proposition. A water may be safe to use and that can be determined by the chemical and bacteriological data. On the other hand an inspection 11131 of the sources of a stream may be entirely misleading and if one should depend upon the personal inspection of a stream and the population upon the same and the sources of pollution which may be above the point examined, from the population and from manufacturing plants, and refuse from establishments of all kinds, one might be easily mislead without having also the chemical and bacteriological data. I consider that the chemical and bacteriological data are very important factors and are absolutely necessary to determine the desirability of a water for use, and whether it can be safely used. The population should be taken into consideration, the changes which the river undergoes and the pollution of the same.

Q. Do you consider that as a sanitary expert you could pass reliable judgment upon the sanitary condition of the water in a running stream at a given point to be used as a water supply of a municipality, without taking into consideration the population residing upon the water shed of that stream, the sources of pollution above the point where the water was being observed?

A. No sir, I could pass upon the quality of a particular sample. I could say that a particular sample from it
11132 was suitable for use but the permanent use of the water supply should involve the study of the surroundings of the same and the pollution to which it should be subjected.

Q. Is it not a fact that the chemical and bacteriological and therefore the sanitary condition of the water in a running stream, such as a river, is continually changing from day to day?

A. It is true that streams are subject to what is known as seasonal fluctuations and that therefore the chemical and bacteriological data necessarily change from day to day.

Q. Is it not a fact that atmospheric changes have an effect upon the bacterial, chemical and therefore sanitary condition of a water?

A. Assuming that by atmospheric conditions you mean rain and snow and cold and heat, it is my opinion that atmospheric conditions do materially affect changes in a running stream.

Q. Is it not a fact, Professor, that sanitarians, in the examination of a water supply are more interested in the character of the bacterial counts than in the number of bacterial counts that appear upon the plates in the bacteriological examination of the water?

A. The numbers of bacteria in waters are important as
11133 showing general conditions in a stream; but it is also true that the character of the bacteria, the species of bacteria, and especially whether any of the bacteria present are of the

so called sewagic types is of great importance in fixing the sanitary character of any given water.

Q. In addition to the number and character of bacteria present in water is not the possible source of such bacteria an important circumstance to be considered?

A. If the analysis shall show the presence of the so called colon forms, especially in water, it becomes a matter of considerable importance to determine from whence they come, and in the study of supplies I have carried that out; particular attention has been given to that phase of the study to determine, if possible, the origin of these colon forms or sewagic forms.

Q. Professor, in the case involving the water supply of the city of Denver, which you spoke of in your direct examination, is it not a fact that while typhoid fever was prevalent in the city of Denver that there was comparatively small number of bacteria in the water as shown by the counts
11134 upon the plates in the bacterological analysis of that water?

A. The number of bacteria in any western water vary, and do not run high in the sense in which we are using it here in this case at least. The investigations in connection with the city of Denver extended, so far as I was concerned, over a period of years, I think about four years, and in the course of those examinations a large number of bacterial and chemical analyses were made, and in general it is to be noted that the numbers of bacteria were comparatively low. The supply at Denver comes from at least four sources, commonly, and each one of these sources was subject to its own conditions. Upon one of them, for instance the Cherry Creek supply the number was very low, under 100, and another supply known as the west side service, the numbers are very low. In both of these supplies the water has undergone a process of filtration. In another source, that of the Marston Lake, the numbers run higher, up to a few thousand, and from the Platte River they would be measured by a few thousand, so that the question needs this amplifying in order not to be misleading.

Of course we have to take into consideration the number of bacteria involved. The Marston Lake and the Platte River

raw waters were high as compared with the others, but
11135 as compared with the eastern streams they are not high, and would be much lower.

Q. Is it not a fact that the bacterial analysis of the water drawn from the supply in the city of Denver, when typhoid fever was prevalent, showed comparatively small numbers of bacteria per cc.?

A. As already stated in the previous answer the number from Cherry Creek were always small and the west side station small, under 100 generally. In testing the west side, the numbers on one occasion suddenly leaped up into the thousands, and it lead to an investigation when we found there was a break in the underground connection. The number from Marston lake ran up into the thousands, and the number from Platte River also were a few thousand.

Q. Are you acquainted with the epidemic which recently occurred in the city of Butler, Pennsylvania?

A. I have read the accounts concerning it as given in the daily press and particularly as stated in the investigations made in behalf of the Engineering News and reported to it by Mr. Soper.

Q. On what stream is Butler situated?

A. I do not know the stream but I understand it is a tributary to the Beaver River.

11136 Q. Are you acquainted with any towns on the Beaver River below Butler?

A. I am. This last summer I was asked by the management of the Beaver Valley Water Company to advise with them regarding the operation of their plant, and I was at Beaver Falls several times rendering services to them.

Q. How far is Beaver Falls from Butler?

A. I do not know.

Q. What is your understanding?

A. I understand about 60 or 70 miles.

Q. Upon hearing of the typhoid epidemic at Butler state whether or not you communicated with your clients at Beaver Falls in relation thereto?

A. Knowing the conditions at Butler, and knowing it was tributary to the Beaver River, at a comparatively short dis-

tance above, I advised the management of the company to be careful in their operation of the plant during the prevalence of the epidemic and the lack of care and disinfecting of the excreta from the typhoid fever patients, and advised that the plant be operated with very great care during this period, and
11137 I understand from letters that they followed that advice.

Q. They have a filtration plant at Beaver Falls?

A. In further explanation of the above question should be added that the Beaver Valley Water Company take their supply from Beaver River, taking it through an intake out in the river. The water is then pumped up to a sedimentation basin where it is treated with alum and then filtered with a so called mechanical filter.

Q. Can you recall the average volume of water flowing down Beaver River?

A. I have no data bearing on that.

Q. Have you ever observed the river?

A. I have been across it several times. It is quite a sizeable stream, emptying into the Ohio a short distance below Beaver Falls. I have been up and down it. I was there in the low stream during the month of August.

Q. How large is Beaver Falls?

A. I am under the impression it must be upwards of 20,000 population. It is one of those iron working towns and is stretched out a long distance. I should judge it was upwards of 20,000 population.

11138 Q. From this letter of advice that you gave your clients at Beaver Falls, it is a fact is it not that the more typhoid material there is deposited in a river there should be greater precautions and more care used in connection with a filter plant there than if there were less of such infection?

A. A filter plant must be worked carefully all the time and the success of any sytem of filtration depends upon the care with which it is operated. Workmen will become careless and this letter was a precaution to them to be sure that the workmen attended to their duty. It was a letter cautioning them to be careful during this epidemic, that no laxity on the part of the service should obtain.

Q. And that precaution upon your part was recommended because of the epidemic which existed on the water shed above, where the water supply was situated?

A. I knew from data at hand and private advices and general knowledge that this river was being polluted at this time, and therefore I cautioned them to be careful in the operation of
the plant. I cautioned them as I should every one to use
11139 due precautions at all times and especially when there was
any reason to suspect that any trouble might arise, from special conditions of the river.

ERASTUS G. SMITH,
Professor Chemistry, Beloit College, Beloit, Wisconsin.

Adjourned until 10:00 A. M., Thursday, March 3, 1904.

10:00 A. M., Thursday, March 3, 1904.
11140 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

JACOB A. HARMAN

a witness called on behalf of the defendants, after being duly sworn by the commissioner, was examined in chief by Mr. Todd and testified as follows:

Q. What is your name?

A. Jacob A. Harman.

Q. Where do you reside?

A. Peoria, Illinois.

Q. What is your business?

A. Civil Engineer.

Q. How long have you been a civil engineer?

A. Since 1887, about 16 years.

Q. Are you a graduate of any institution of learning?

A. I graduated at the Normal University at Lebanon, Ohio, in 1887.

Q. Did you take a technical training at any institution?

A. I took the civil engineering course there.

Q. Have you been connected with any institution of tech-
11141 nical character except that since your graduation?

A. No sir.

Q. What work have you done in the line of civil engineering, briefly?

A. Well, the first two years after graduation I was doing country surveying and drainage engineering and in 1890 I went to Peoria and was assistant engineer in the construction of the water works there for about a year and a half, and the beginning of 1892 I established an office in Peoria for general engineering practice, civil engineering and then in 1893 I was appointed City Engineer of Peoria and continued in that position for two years, and since that time I have been doing general civil engineering work, water supply, sewerage and drainage and general surveying. For the last five years I have been consulting Engineer to the State Board of Illinois.

Q. Are you acquainted with the general physical characteristics of the Illinois River?

A. Yes sir.

Q. Will you give a general description of the Illinois valley, the territory which is drained by the Illinois River, stating the character of the territory drained to what interest it is devoted and the towns situated upon the water shed of the
11142 Illinois River?

A. The Illinois River drains about one-half of the territory of the state of Illinois and a small portion in the southeast corner of the state of Wisconsin and a portion of the northwest corner of the state of Indiana.

The immediate valley of the Illinois River is described in the report on the Water resources of Illinois by L. Everett, of the Geological Survey of the United States. This description is condensed and gives it in about the best form, and I will read quotations from that description:

"The Desplaines and the Illinois River form what has been regarded by geologists as an ancient outlet for Lake Michigan and the other lakes which flow into it, and by that large flow of water from that territory has cut a very much larger channel through the state (now occupied by the stream) than required by the drainage of the territory now drained by the Illinois River." That description is as follows:

I am reading from page 103 of the report of the Illinois

State Board of Health, Sanitary Investigation of the Illinois River and its tributaries, of 1901.

"The Southwestward or Chicago outlet of Lake Michigan, as pointed out some years since by Col. James H. Wilson,
11143 and Wm. Gooding, C. E. by Dr. H. M. Bannister, and by
Dr. Edmund Andrews, entered the present Desplaines Valley immediately west of Chicago, and passed thence down the Illinois. The effect of this outlet upon the size of both the Desplaines and the Illinois, is very marked. The upper portion of the Desplaines, down to the point where the ancient stream entered the valley, is a small channel, 20 to 30 feet in depth and scarcely one-eighth mile in width, cut into soft deposits of glacial drift. Upon entering the outlet the stream finds a valley more than a mile in average width, and cut to a depth of 50 to 100 feet or more, the depth varying with the altitude of bordering uplands. The excavation is mainly in drift, but for a few miles above Joliet it extends 25 feet or more into the rocks."

"The Illinois flows for a few miles in a low drifted basin lying west of the Marseilles Moraine, in which the ancient stream was expanded into a lake which built beeches instead of eroding a channel, but from the Marseilles Moraine, onward, a large valley is cut, having an average depth of more than one hundred feet, and a width of about one and one-half miles
throughout the new course above Hennepin, and nearly
11144 three miles in the old part of the valley below that town."

"To appreciate how small a part of this excavation on the Illinois is due to the present drainage lines, one has only to turn to such tributaries as the Fox, and Vermillion Rivers, and compare the small channels cut by them with the large valley of the Upper Illinois, for they are all cut to about equal proportions, in the drift, and in rock formation of a similar kind. Fox river, which includes about one-fourth of the present drainage of the upper Illinois, has in its lower seventy five miles, a channel with about one-eighth the width and one-half the average depth of the upper Illinois, and is even better favored than the Illinois, in its rate of descent. Instead of 25 per cent of the amount of excavation displayed by the Illinois, this stream has accomplished scarcely one-fourth that amount. It seems probable that at least three-fourths of the excavation of the upper

Illinois, and even more of the portion of the Desplaines occupied by the late outlet, was accomplished by some ancient stream. In the lower Illinois, where the ancient stream worked entirely upon the loose materials of the drift, the excavation was larger in amount, and the valley presents a remarkably low
11145 gradient,—so low that the present stream is silting up
instead of eroding its bed. The fall of the present stream, in its lower 220 miles, is but 30 feet. Whether this very low gradient is entirely due to the lake outlet, or has been brought about in part through the warping of the valley, has not been determined. It is certain, however, that the valley was opened throughout its entire course to a far greater extent than the present stream could have accomplished.

"Of the streams which traverse Illinois, the Illinois is by far the largest, its drainage area being fully half as great as the area of the state and lying mainly between the State's boundaries.

"The drainage or water shed of the Illinois extends in a broad band, averaging one hundred miles in width, in the northeast, southwest direction, directly across the center of the state. From the northeastern extremity of this band there are two projections,—one north into Wisconsin, including the Fox and Desplaines River basins; the other east into Indiana, including the Kanakee and its main tributary, the Iroquois. The name Illinois is appiled to the river from the junction of the
11146 Kankakee and Desplaines. The western side of the water
shed is twenty to forty miles in width, while the eastern side is 60 to 80 miles.

"The Illinois River is a stream showing a marked contrast in the rate of fall. From the junction of the Desplaines and Kankakee westward for fifty miles, being in a new course, its bed usually on the rock, it has an average fall of about one foot per mile; but in the remainder of its course to the Mississippi, a distance of about 225 miles, it is in a pre-glacial channel, and has, as previously stated a very slight fall."

The principal tributaries to the Illinois River are the Desplaines and Kankakee (which by their junction form the beginning of the Illinois River), the Fox River, the Vermillion

River, the Spoon River, Mackinaw River, the Sangamon River, Macoupin Creek and Crooked Creek.

The entire drainage area of the Illinois River is devoted extensively to agriculture, and pasturage. Stock raising is one of the chief pursuits of the rural inhabitants of this territory. A very large urban population also exists upon this terri-
11147 tory, the principal cities being Peoria, Springfield, Pekin, Bloomington, Decatur, LaSalle and Joliet. All of these cities are extensive manufacturing points.

MR. JEFFRIES: I move to strike out all that part of the answer where the witness read into the record quotations from the Report of the Illinois State Board, for the reason that it is incompetent and not proper testimony.

11148 Mr. Todd: Have you made an investigation of the population on the Illinois Water shed as well as in the city of Chicago?

A. Yes sir.

Q. Will you describe the results of that investigation and upon what statistics the investigation was based?

A. The investigation was based upon the United States census report. I have made an investigation of the growth of the population in the city of Chicago, but the details of that are already in evidence in Mr. Randolph's report. I have also made an investigation of the population of all that part of the Illinois water shed except the city of Chicago, the results of which are set forth in detail showing a division of the population into urban and rural population for the two census years 1890 and 1900. This population has been tabulated so as to show the numbers upon each of the subdivisions of the Illinois water shed, as the Desplaines River water shed, the DuPage, the Kankakee, the Fox, the Vermillion, the Mackinaw,
11149 the Spoon, the Sangamon, Crooked Creek and the Macoupin Creek, and the population which is directly tributary to the Illinois and not upon its branches.

This table was prepared as a part of my report to the State Board of Health and is published in the Sanitary Investigation of the Illinois River and its tributaries in 1901, page 119, and is as follows:

Illinois River Drainage Basin Recapitulation Table—Popvlation Various Sub-Basins.

Drainage Basin.	Total Population 1890.			Total Populat'on 1900.			Numerical Increase.			Per Cent. Inc.

— Indicates Decrease. * Census for Indiana and Wisconsin in 1900 not at hand, and that of 1890 used.

The classification of urban population and rural population
11151 is taken upon the basis of that people living in cities and villages of 1,000 or more are included in the urban population and all others are included in the rural population. This classification has been made for the reason that villages of less than 1000 population seldom have any public water supply or public sewerage system and the villages and cities of more than 1,000 population generally have public water supplies and many of them have public sewerage systems.

Besides the total population for the two census years 1890 and 1900 the table also shows the numerical increase in urban and rural and total populations and the per cent of increase.

The most striking fact brought out by this table is that the rural population during the decade 1890 to 1900 has been practically stationary. The total increase is attributed to the increase in city growth or urban population. The Desplaines territory shows an increase in rural population, and also the Kankakee. The Vermillion, the Sangamon, Crooked Creek, the Mackinaw and Macoupin Creek all show a decrease in rural population.

11152 The total increase in urban population was 135,594 and the total increase in rural population was 5,449.

The greatest per cent of increase of population in any district was on the Desplaines water shed; on Crooked Creek which has no cities there was an actual decrease in total population.

Q. Have you made any calculations upon the rainfall in the different drainage basins in the Illinois River?

A. Yes sir, I have.

Q. How extensive has been your investigation of that question?

A. I have made an investigation of the rainfall for the 11 years of 1890 to 1900, inclusive, using the weather bureau published reports of rainfall as published by the Weather Bureau of the United States. These rainfall records have been compiled for each of the drainage basins of the Illinois River, as described in my testimony regarding the subdivision of the population of the Illinois River basin. My investigation includes the average rainfall by months and for each year during that period of time.

Q. Have you prepared a list of the annual rainfalls in the valleys tributary to the Illinois River?

11153 A. Yes sir, that list comprises ten years, 1890 to 1899, inclusive, and gives the rainfall for each year and the average rainfall in the Desplaines, the Dupage, the Kankakee, the Fox, the Vermillion, the Mackinaw, the Spoon, the Sangamon, Crooked Creek, Macoupin Creek, McKee's Creek and the Illinois River for all these years.

This in tabular form is published, page 159 of the "Sanitary Investigations of the Illinois River and its Tributaries, 1901," by the Illinois State Board of Health, and is as follows:

11154

Resume of Precipitation on Illinois River Basin.

Illinois River direct	28.19	33.92	40.93	30.61	26.65	32.72	35.05	33.12	46.77	33.05	34.01
Annual averages	31.18	33.13	40.56	31.03	27.82	32.29	36.61	33.42	45.73	31.90	34.36

11155 This table shows in the right hand column the average rain fall for the ten years for each of these water sheds, and in the lower line of figures of annual averages for the entire drainage basin of the Illinois. The average rainfall for the whole water shed for ten years was 34.36 inches.

The characteristic shown by this table is that the average annual rain fall is greater in the southern portion of the Illinois valley than in the northern portion.

The average annual rain fall on the Desplains River was 31.82.

The average annual rain fall on McKee's Creek, the most southern tributary given was 37.37.

This rainfall data included the rainfall and the snow as measured by melting a measured depth of water which it would produce.

Q. What effect is manifest upon the Illinois River itself by this annual rainfall coming from snow and rain as you have indicated?

A. The rainfall data which has gone in evidence is the annual amounts and averages. This rain comes at intervals and frequently raises the rivers to extreme height and especially in the spring when the snow is going off the ground, and
11156 the ground is frozen, the decaying vegetable and other organic matter, especially from the pastures, barn yards, etc., is washed off into the smaller streams and then finds its way into the Illinois River producing a pollution of the stream making it muddy and dirty during flood periods.

Q. Have you prepared any discharge measurements of the Illinois River?

A. I have.

Q. At what point?

A. The discharge measurements were made at Peoria on the Illinois River. The cross-section was taken at the P. & P. U. R. R. Bridge, which is the bridge farthest down the stream at the city of Peoria. At that point the railroad embankments are filled to the bridge abutments so that the entire flow of the river must pass between the piers of the bridge. A cross-section of the river was taken at this place and the velocity of the stream was measured by a current meter and from these measurements of the cross-section and the velocity of flow the discharge of the Illinois River was computed.

11157 Q. Have you the gauge readings of the Illinois River at that point?

A. I have.

Q. Covering what period?

A. From 1890 to 1903, inclusive.

Q. Are these total gauge readings published?

A. Yes sir.

Q. In what report?

A. The daily gauge readings of Illinois River taken at Peoria are published in the weather bureau reports of the United States Government and the daily stages from 1890 to 1900, inclusive, are also published in the Illinois State Board of Health Report of the Sanitary Investigation of the Illinois River and its Tributaries, 1901, pages 167 to 172, inclusive. Since that time the gauge readings which I have here are copied from the original record, and they are published from time to time by the weather bureau.

Q. Have you prepared a table of discharges, based upon the gauge readings, published and found as you have indicated in the Board of Health reports and the reports of the weather bureau?

A. Yes sir, I have. The discharge tables of the Illi-
11158 nois River for the years 1890 to 1900, inclusive, have
been prepared showing the discharge in cubic feet per
second for each month for that period of 11 years. This table
is also published in the Illinois State Board of Health reports
above referred to, pages 177 to 179 inclusive.

Q. Have you prepared, from these monthly reports of the discharges and gauge readings already referred to a table of the annual discharges at Peoria?

A. Yes, I have prepared a table of annual discharges for the Illinois River at Peoria, covering the years 1890 to 1903, inclusive. The table is as follows:

11159

Table of Annual Discharge Data of Illinois River at Peoria.

Year.	Maximum cu. ft. per sec.	Minimum cu. ft. per sec.	Mean cu. ft. per sec.	Average for middle half cu. ft. per sec.	Ordinary cu. ft. per sec.
1890	25,996	723	7,893	6,554	4,438
1891	30,985	786	5,289	2,900	2,135
1892	69,031	1,850	13,396	6,784	4,612
1893	54,570	992	10,906	5,900	3,427
1894	19,277	1,066	4,460	3,222	2,599
1895	30,554	1,066	3,338	2,134	1,843
1896	28,027	1,474	8,099	7,257	6,040
1897	47,019	1,564	11,173	6,955	4,409
1898	52,706	1,387	11,923	8,294	6,043
1899	31,417	1,303	7,378	4,637	3,400
1900	56,401	2,874	12,026	8,204	6,929
1901	43,788	3,648	8,351	6,163	5,338
1902	63,339	5,725	20,634	18,851	14,750
1903	52,706	8,971	20,417	17,216	14,437
Averages for 14 ye'rs	43,281	2,388	10,382	7,498	5,754*
Average without Chicago Riv. flow.	41,663	878	8,761	5,880	4,239

The average discharge for the Chicago river 1890 to 1899, inclusive, taken as 600 cu. ft. per sec.

The ordinary discharge through the Chicago river from 1900 to 1903, inclusive, computed at 4162 cu. ft. per sec., by using the same quantity for 1903 as was found in 1902, i. e., this amount seems to correspond to the conditions existing during time of condition of ordinary flow in the Illinois river.

11160 This table of discharges shows in the first column the year, in the second column the maximum discharge for any date in cubic feet per second, the third column shows the minimum discharge in cubic feet per second the fourth column shows the mean discharge in cubic feet per second, the average for the entire year, the fifth column shows the average discharge for the middle half in cubic feet per second and the sixth column or last, shows the ordinary discharge of the Illinois River in cubic feet per second.

Now, to explain this table, so that the data in these various columns will be understood, I will go back a little and refer again to the observations made to determine the velocity of the river at Peoria and from the velocity the discharge.

Observations were made of the velocity of the river during the years 1889 to 1900 at various stages, ranging from 4.8 inches to 19 feet 3 inches. The gauge readings of which have been referred to.

The record of these observations showing the discharge in cubic feet per second and the average velocity of the stream at the time of each of these observations are also set
11161 out in the table, which is as follows:

Discharge of Illinois River at Peoria, Illinois.

(Computed from Current Meter Observations and Cross-sections.)

Dates.	Stage of River.		Discharge.	Velocity.
	P. & P. U. R'way Bridge.	Bridge Street Bridge.	Cu. Ft. Second.	Ft. per Second.
Oct. 19, 1899	4′ 8″	4.3	2,136	....
Mar. 13, 1900	15′ 11″	15.4	33,797	2.432
Mar. 15, 1900	19′ 3″	19.2	51,086	3.001
Mar. 29, 1900	15′ 8″	16.0	30,483	....
May 23, 1900	8′ 11″	8.8	9,296	1.153
June 27, 1900	7′ 4″	7.2	6,600	1.041
Aug. 29, 1900	7′ 9″	7.7	6,817	1.021
Sept. 27, 1900	5′ 10″	5.8	4,558	0.890

NOTE.—The observation of March 29, 1900, is not accurate on account of the drift material and has been disregarded in preparing the curve of discharge.

11162 From this table of measured discharges a discharge curve or diagram was plated from which to determine the discharges of the Illinois River at stages intervening between the points where the observations were taken. This diagram was plated on paper that was ruled vertically and horizontally.

On the horizontal lines near the bottom at intervals are marked the discharges in cubic feet per second and on the vertical lines the stages of the river, that is from zero stage to 22 feet. Upon this paper was first plated the position of the discharge observation. Through this point was drawn an average curve.

In order to facilitate computations a table of discharges was made up for the stages of the river from 1 foot to 22 feet by tenths of a foot. This table is published in the Illinois State Board of Health above referred to, page 176 and is as follows:

11163

Table of Discharges in Cubic Feet Per Second at Peoria, Ill., for Stages of Two to Twenty-two Feet, by Tenths on Gauge at Bridge Street Bridge.

11165 Using the daily stages of the Illinois River and the discharge table, the total discharges of the Illinois Riv were determined for each of the years under consideration, and from these total discharges the results found in the table of annual discharge data of the Illinois River at Peoria were computed.

The maximum discharge indicates the discharge for the highest stage of the river. The minimum discharge is for the lowest stage of the river, and the mean is the average of the entire year.

The ordinary flow of the Illinois River is determined by a rule for arriving at the ordinary flow of streams, which was proposed by Mr. Leslie, a civil engineer, and is given in the minutes of the proceedings of the "Institution of Civil Engineers," Volume 10, page 327. These poceedings were published, I think, in the year 1851.

The rule of Leslie is as follows:

11166 "Range the discharges as observed daily in their order of magnitude.

"Divide the lists thus arranged into an upper quarter, and middle half, and a lower quarter.

"The discharges in the upper quarter of the list are to be considered as floods, and in the lower quarter as minimum flows

"For each of the gaugings exceeding the average of the middle half, including the flood gaugings, *substitute the average of the middle half of the list,* and take the mean of the whole list, and thus modified, for the *ordinary* or *average discharge, exclusive of flood waters.*"

Using this rule I have computed and shown upon this table of annual discharges the averages for the middle half and the ordinary flow in cubic feet per second.

The discharge data given in this table includes the flow of the Chicago River which is discharged into the Desplaines at Lockport and Joliet.

11167 I have also prepared a table of discharges of the Illinois River as affected by the principal tributaries. This table is divided into two periods, ten years, 1890 to 1899, inclusive, and four years, 1900 to 1903, inclusive, the latter period being since the opening of the drainage canal.

This table is based upon the discharge as measured at Peoria, and the amount contributed by each of the tributaries to the Illinois is estimated as being in same ratio as the area of the tributary bears to the total drainage area above Peoria. The title of the table is as follows: "Table of volume of flow of the Illinois River as affected by its tributaries, based on discharge measurements at Peoria, and ratios of drainage areas," and is as follows:

TABLE OF DISCHARGES OF THE ILLINOIS RIVER AS AFFECTED BY ITS TRIBUTARIES; BASED ON DISCHARGE MEASUREMENTS AT PEORIA AND RATIOS OF DRAINAGE AREAS.

JACOB A HARMAN CE

NOTE; IN ABOVE TABLE "LOW" = AVERAGE FOR LOW QUARTER, "ORD" = ORDINARY AND "HIGH" = AVERAGE FOR HIGH QUARTER.

11169 This table shows the approximate distances along the Desplaines and Illinois Rivers, from Lockport to the point of entrance of the various tributaries. The ratio of the area of the various tributaries to the area at Peoria, and the sum of those ratios proceeding down stream. Two sets of discharges are computed for both of the periods referred to. One set of discharges is for the natural flow of the Illinois River, exclusive of that contributed by way of the Chicago River and the other is for the total flow of the Illinois River. The discharge is also given for three stages of the river, that is, low, ordinary and high. The low, as given in this table, is the average flow of the river for the 91 days of the year when the river was lowest or low quarter of the Leslie rule. The high or flood discharges are for the 91 days of the highest discharge of the river, or the average for the high quarter of the Leslie rule. The ordinary is computed by the Leslie rule which has been given before.

For the ten year period, 1890-99, this table shows that the
low flow of the Desplaines River without the Chicago
11170 River contributing, averaged 94 cubic feet per second,
the ordinary 334 cubic feet per second and the high
1788 cubic feet per second.

The flow of the Kankakee and Desplaines jointly was 444 cubic feet, the ordinary 1577 cubic feet, and the high 8424 cubic feet, without the Chicago contributing.

The table shows that the average discharge from the Illinois into the Mississippi for the ten years, 1890-99, inclusive, for the low quarter 1904 cubic feet, the ordinary 6747 and the high 36045 cubic feet, without the Chicago contribution. In these tables the amount of water supplied through the Illinois and Michigan Canal from Chicago has been estimated as 600 cubic feet per second, throughout the entire period.

For the years 1900 to 1903, inclusive, the Chicago drainage canal and the Illinois and Michigan Canal jointly have contributed to the flow of the Desplaines and the Illinois River at the low period, 3801 cubic feet, the ordinary and high periods, 4162 cubic feet per second. The average discharge of the Illinois and its tributaries during the four years, 1900 to 1903, inclusive,

has been considerably in excess of the average discharge for the previous ten years, not taking into account the Chicago
11171 River contribution.

Comparing the discharge of the Illinois into the Mississippi, the low flow for the latter four years, as compared with the former ten years, was nearly three times as great, the ordinary flow at the high or flood flows, about 80 per cent more, these exclusive of the sanitary canal waters.

Q. Have you investigated the city of St. Charles, Missouri?

A. Yes sir, I have made an investigation there.

Q. When was this investigation made?

A. On March 10th and 11th, 1903.

Q. Will you describe the sewage system of St. Charles, briefly, and whether it sewers into the Missouri River?

A. All the sewers of the city of St. Charles, all drain into the Missouri river. The city of St. Charles is located upon the left bank of the Missouri River, above where it empties into the Mississippi River. The distance over land from St. Charles to the business district of St. Louis is about sixteen miles. The land upon which St. Charles is situated rises abruptly from the Missouri River and at a distance of about three or four blocks back from the river the elevation is about 100 feet or more above the stream. The drainage of the business dis-
11172 trict and of nearly all the residence district flows direct
into the Missouri River. The drainage of the remainder of the residence district is north to the Mississippi River, which is only 6 miles away. The streets run parallel with and at right angles to the Missouri River. The business is done on the first two streets, parallel with and near the Missouri River. The population of St. Charles, in 1890, was 6,161, and in 1900 it was 7.982, from the United States census reports. St. Charles is not provided with a complete sewage system. There are four public sewers ranging from three or four blocks in length to eight blocks in length, draining the business districts, and portions of the more populous territories. Besides these there are many private sewers from the hotels and business houses leading to the Missouri River. On Main Street, which is parallel with and one block from the river, there are five hotels and one or two livery stables. There is a public hospital which can

accommodate about twenty patients located four blocks from the river, which has a sewer on Clay Street.

Q. Are you acquainted with the sewage system of St. Louis?

A. In a general way.

Q. Do you know how St. Louis disposes of its sewage?

11173 MR. JEFFRIES: Objected to as immaterial.

A. The sewage of St. Louis is discharged by means of main sewers into the Mississippi River.

Q. Do you know how the garbage and the cleanings of the streets are disposed of?

MR. JEFFRIES: I object to that as immaterial.

A. They are disposed of by dumping into the Mississippi River from city dump boats, stationed at various places along the river line.

Q. Will you look at the photograph on page 1 of defendants' exhibit, Spencer's exhibit C, and state whether that photograph correctly represents the manner of the disposal of garbage in the city of St. Louis?

A. I should say it does.

MR. JEFFRIES: I object to the question as immaterial and to the answer, and I move to strike out the answer for the same reason. Also for the further reason that the photograph does not show that any garbage is being deposited at the place where the photograph was taken.

Q. Describe how the garbage of St. Louis is disposed of along the Mississippi River?

11174 MR. JEFFRIES: Objected to as immaterial.

A. At a number of points along the Mississippi River along the river front of St. Louis, the city maintains what are called dump boats which are scows 30 or 40 feet wide and 80 to 100 feet long, and which are tied near the bank, and the wagons and the teams having the garbage are driven upon these boats, and the garbage is dumped over the edge into the river and it floats off down the stream.

ADJOURNED until 2:00 p. m., same day.

11175 2:00 p. m., Wednesday, March 3, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

JACOB A. HARMAN

resumed the stand for further direct examination by Mr. Todd, and testifies as follows:

Q. Mr. Harman, have you in your possession a copy of a letter addressed to James P. Kirkwood, Esq., chief engineer, from the office of the Board of Water Commissioners of the city of St. Louis, dated December 11, 1865?

MR. JEFFRIES: I object to the question because it is incompetent, irrelevant and immaterial, and has no bearing upon the issues involved in this case, and the letter itself is so antiquated as not to be competent, dated prior to the birth of the science of bateriology and modern sanitary science, and for the further reason that counsel has exhibited to the witness a book which purports to contain a copy or supposed copy of said letter, and such testimony is incompetent, irrelevant and im-
11176 material.

A. Yes sir.

Q. Where does such letter appear?

MR. JEFFRIES: I object to the letter for the same reason and for the further reason that it will have no bearing upon the issues involved in this case and can have no binding force upon the complainant.

A. This letter appears on page 165 of the report on the filtration of river waters for the supply of cities as practiced in Europe, made to the Board of Water Commissioners of the city of St. Louis by James P. Kirkwood, civil engineer, published by permission of the Board by D. Van Nostrand, publisher, 23 Murray Street and 27 Warren Street (up stairs), London. Thubner & Co. 1869.

Q. Will you read into evidence the letter to which you refer?

MR. JEFFRIES: I object to the reading of the letter in evidence for the same reasons stated in the previous objection.

A. Office of Board of Water Commissioners, St. Louis, December 11, 1865.

11177 James P. Kirkwood, Esq., Chief Engineer:

Dear Sir.—At a meeting held this day at the rooms of the Commissioners there were present his Honor, the Mayor, J. S. Thomas, Philip Weigel and Dwight Durkee, President Mayor Thomas offered the following resolution, to-wit:

Resolved, that James P. Kirkwood, Esq., our chief engineer, be requested to proceed at once to Europe and there inform himself in regard to the best processes in use for the clarifying of river waters used for the supply of cities, whether by deposition alone or by deposition and filtration combined, making such an examination in each instance as will enable him to report to this board the general dimensions and special characteristics of the specific works visited by him, so that this board may be able to appreciate how far the same mechanically and the same or similar combinations of materials are likely to be adaptable to the purifying of the Mississippi water at St. Louis.

11178 The following cities which are supplied by river water and which possess works for the cleansing of that water when turbid are indicated as points to be visited, to-wit:

In England, London, Norwich, Preston, Nottingham and South Hampton.

In Scotland: Paisley and Perth,

In Ireland: Dublin.

In France: Lyons, Tours and Toulouse, and Marseilles.

In Germany: Berlin, Hamburg and Brunswick.

In Italy: Leghorn.

And such other cities not above mentioned as may be ascertained to possess works of this class deserving of the examination to be visited, also provided, however, that Mr. Kirkwood shall so arrange his movements as to return to St. Louis by the first day of May, 1866, at the furthest.

Resolved that Mr. Kirkwood be and he is hereby empowered to employ such assistants or interpreter when in Europe, and particularly where foreign languages are spoken, as may be necessary to enable him to get all the information needed.

Above I hand you copy of resolution and to enable you to carry that out I enclose herewith my individual check number 30,009 on the National Bank of North America, New 11179 York, for twenty-seven hundred dollars, which I trust will be sufficient for the full trip.

I have to request that you advise me of the receipt of this, also what day you sail and any other particulars you choose, and further that you will report your arrival on the other side with such observations as your time and inclination will permit.

With the hope that you find an ever ruling Providence will guide and protect you, I remain,

Yours truly,
(Signed) DWIGHT DURKEE,
President.''

MR. JEFFRIES: I move to strike out the letter as read for the reason that it purports to be a duplicate copy and no evidence is shown that it is an exact copy of the original or any such letter was ever written, or any such resolution ever passed or any such authority ever given and it is irrelevant and immaterial testimony and incompetent.

11180 CROSS-EXAMINATION by Mr. Jeffries.

Q. What did you say was the extent of the sewer system in the city of St. Charles, Missouri, as you observed it?

A. There were four public sewers there extending three or four blocks to ten or twelve blocks, from the river, draining the major portion of the business district and considerable of the residence, the more thickly populated residence district, including most of the school houses of the city and the hospital.

Q. Is it not a fact that less than one-third of the city of St. Charles is sewered?

A. In area less than one-third.

Q. In population is it not true?

A. I do not know definitely about that. I do not say it would be less than one-third.

Q. It is a fact that there is not more than one-third?

A. I do not think half of the population.

Q. Do you know the population of the city of St. Charles?

A. As given by the census.

Q. What is it?

A. I do not recall the figures. I gave it in my testimony this morning, nearly 8,000.

11181 Q. What part of the current of the river with reference to its surface and its bed is the most rapid?

A. With reference to the sides of the prominent obstructions in the river, the central portion. With reference to the depth, about from .1 to .2 below the surface is most rapid.

Q. 1.2?

A. From .1 to .2 of the total depth of the stream, below the surface.

Q. From .1 to .2?

A. Yes sir, from .1 to 2. of the depth.

Q. So then if the stream was 10 feet deep the most rapid place would be from 1 to 2 feet below the surface?

A. And in the center of the stream.

Q. And in the center of the stream?

A. Yes sir.

Q. In figuring up the total urban and rural population upon the water shed of the Illinois River what did you include in the urban population?

A. I included the population of all cities or villages of 1,000 or more inhabitants.

11182 Q. And you included all the villages with a population of 1,000 or more that are situated upon the water shed, or what is known as the water shed of the Illinois River?

A. Yes sir, or drainage area.

Q. Or drainage area?

A. Yes sir.

Q. All the remainder of the population as shown by the census was placed in the column known as rural population?

A. Yes sir.

Q. You live at Peoria?

A. I do.

Q. Do you know where the Clark Brothers present distillery is located?

A. I do.

Q. How long have they occupied that present distillery?

A. About five or six years.

Q. Their old distillery is closed down?

A. Yes sir, it is dismantled or closed down, or torn down.

Q. How far is their present distillery located from the Illinois River?

A. About a half a mile.

11183 Q. A wide area of vacant territory between the distillery and the river?

A. Yes sir, it is a river bottom and years of low water it is all farmed.

Q. Cultivated?

A. Yes sir.

Q. This letter that you introduced or read in evidence from the book, where did you get that book?

A. You mean today?

Q. Yes sir?

A. I borrowed it from the Western Society of Engineers' library. I have a copy in my own library at home.

JACOB A. HARMAN.

ADJOURNED until 10:00 a. m., Friday, March 4, 1904.

11184 1:30 p. m., Friday, March 4, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

ROBERT SPURR WESTON,

a witness called on behalf of defendants, being duly sworn, testified as follows:

DIRECT EXAMINATION, by Mr. Todd.

Q. What is your name?

A. Robert Spurr Weston.

Q. Are you a graduate of any technical college?

A. I am a graduate of a college.

Q. What college, Mr. Weston.

A. Amherst.

Q. When did you graduate at Amherst?

A. 1891.

Q. What degree did you take at Amherst?

11185 A. Bachelor of Science.

Q. After graduating from Amherst what did you do?

A. I was employed as chemist for about three years.

Q. Where?

A. With the American Sugar Refining Company, and also on a plantation in Louisiana. After that I was a student in the Institute of Technology and in the University of Berlin, and besides that I have been a volunteer worker in the laboratories of the Massachusetts and the German Imperial Boards of Health. Since then I have been engaged in sanitary work. In 1895 I was connected with the Louisville water purification experiments and subsequently have been connected with water purification experiments at West Superior, Wisconsin, at Washington, D. C., and other places.

In 1900 I was in direct charge of the water purification station at New Orleans and conducted an investigation lasting eight months as to the feasibility of purifying the Mississippi water. I have been in private practice, exclusive of this last period, for six years.

Q. Are you acquainted with the watershed of the Mississippi river above New Orleans?

A. Yes, sir.

11186 Q. Have you prepared a table of distances of the towns lying tributary to the Mississippi river watershed above New Orleans?

A. I have prepared a table of distances.

Q. Will you read the principal cities, their distances from New Orleans, lying on the Mississippi river or its tributaries?

MR. JEFFRIES: I object to the question because it is incompetent and immaterial and has no bearing upon the questions involved in the issues in this case.

A. Baton Rouge, Louisiana, 132 miles.
Natchez, Mississippi, 265 miles.
Vicksburg, Mississippi, 366 miles.
Memphis, Tennessee, 735 miles.
Cairo, Illinois, 965 miles.
Louisville, 1305 miles.
Cincinnati, 1415 miles.
Pittsburg, 1875 miles.

St. Louis, 1159 miles.
Mouth of Missouri river, 1165 miles.
St. Paul, 1823 miles.

Q. Have you figured out the population upon the water-
11187 shed of the Mississippi river above New Orleans?

A. I have.

MR. JEFFRIES: I object to that.

Q. Have you prepared tables showing the urban and rural population on the watershed of the Mississippi river above New Orleans?

A. I have not prepared a table showing the urban and rural population. I have prepared a table showing the population of the cities which have 25,000 or more inhabitants, and the cities having a population of 4,000 or more inhabitants.

Q. That population in cities less than 4,000, that is, the rural population, have you prepared?

A. No, I have not.

Q. For what years have you prepared this table of the urban population in cities of 4,000 or more?

A. For the year 1900.

Q. How was this population for 1900 secured?

A. From the United States census for 1900.

Q. What did the United States census for 1900 show the population to be in towns of 4,000 or more in the Mississippi river valley?

11188 A. About 9,000,000, including Chicago.

Q. Have you prepared an estimate of the amount of sewage sewering into the different rivers which make up the watershed of the Mississippi river?

MR. JEFFRIES: I object to that as immaterial.

A. I have.

Q. Upon what basis have you prepared this data?

A. I have assumed that cities which have a population of 25,000 and over will discharge 175 gallons per capita of sewage per diem. I have assumed that the remainder of the urban population would produce 100 gallons per day per capita of sewage.

Q. Upon what was the assumption based made as to the amount of sewage in large cities as compared with small cities, with small cities having the ratio of 175 to 100 gailons per capita?

A. The assumption was based upon the water supply. In the case of the larger cities it was found, according to tables prepared, by John R. Freedman, in a report presented to Bird S. Coler, comptroller of the City of New York, that the large cities of the country consumed about 100 gallons of water per capita per diem. The 75 gallons per day is added for sewage from the streets, for ground water flowing into the sewers and for contaminated water from any other sources.

11189 In the smaller cities the consumption of water is much lower, approximately 60 gallons per capita. Furthermore, a large percentage of these cities is not sewered and a correspondingly smaller estimate must be made in this case for the difference between the amount of water consumed and the amount of sewage produced.

MR. JEFFRIES: I move to strike out that part of the answer which pertains to the quantity of water, consumption per capita in the large cities and the small cities, for the reason that it is in conflict with testimony already introduced by respondents, to wit: the evidence of Mr. Randolph, and this statement is inconsistent with the complainant's own testimony.

Q. Have you figured out the volume of sewage, based upon the large cities, on a basis of 175 gallons per capita per day as well as those upon the smaller cities?

MR. JEFFRIES: I object to the question for the reason that the counsel does not differentiate between what he terms large and smaller cities.

MR. TODD: In reply will state for the benefit of counsel that the matter has already been differentiated in the previous testimony of this witness, and for that reason I deemed it unnecessary to repeat it. 11190

A. I have. I estimated the amount of sewage from large cities, that is, cities above 25,000 population, to be 1,174,250,000 gallons per day. I estimated the amount of sewage from the remainder of the urban population, that is, the remainder of the population of cities from 4,000 to 25,000 to be 342,000,000 gallons per day, making a total of 1,516,250,000 gallons a day. This is equivalent to a flow of 2310 cubic feet a second at New Orleans.

Q. Have you figured out the dilution of the sewage at New Orleans?

A. I have. These dilutions may be expressed in three different ways:

A. Maximum dilution 1 of sewage to 586 of water.
Minimum, 1 of sewage to 83 of water.
Average, 1 of sewage to 296 of water.

B. Expressed as cubic feet per second of sewage per 1,000 urban population:

Maximum, 150. Minimum, 21. Average, 75 cubic feet per second per thousand urban population for the year 1900.

C. As gallons of water per diem per capita of the urban
11191 population:

Maximum, 16160. Minimum, 2262. Average, 8190.

Q. When you were at New Orleans what branch of the work did you have charge of in connection with the survey of the water of the Mississippi river, at that point?

A. I had the superintendence of the whole work.

Q. Who had charge of the work?

A. I was under the direct supervision of the Chief Engineer of the Sewage and Water Board.

Q. Who was the chief engineer?

A. George G. Earle.

Q. What other engineers were associated with that work?

A. There was an advisory board of six engineers of whom Mr. George W. Fuller of New York was the one with whom I came in direct contact. The advisory board consisted of B. M. Harrod, of New Orleans; Mr. Bell, of New Orleans; Mr. Raymond (deceased); Mr. Rudolph Hering, of New York; Mr. George W. Fuller, of New York, and Mr. Brown, of New Orleans.

Q. What branch of this work did you have charge of?

A. I was in charge of the water purification station.

11192 Q. When was the work done at this water purification station?

A. In 1900 and 1901 an experiment was conducted for eight months and data was collected for somewhat longer time to determine the best method of purifying the Mississippi river water at New Orleans.

Q. What was the character of the data?

MR. JEFFRIES: I object to that as immaterial.

A. The data consisted of analyses, engineering data and reports.

Q. What kind of analyses?

A. Chemical and bacteriological.

Q. Did you have charge of the chemical and bacteriological analyses conducted at this station?

A. I did.

Q. Over what period of time did these bacterial and chemical surveys of the waters of the Mississippi cover?

A. From the last of November until the following September, practically over one flood season.

Q. How often were analyses made of the waters of the Mississippi river?

A. As a rule, daily.

Q. At how many points?

A. At one point.

11193 Q. Where was that point located in the Mississippi river?

A. It was located at the upper confines of the City of New Orleans and where the experiment station took its water for experimental purposes.

Q. Were these analyses that were made daily both chemical and bacterial?

A. They were.

Q. Were the results of the chemical and bacterial analyses for the entire period ever published?

A. They were published in the report on Water Purification, published in New Orleans in 1903, by the Sewerage and Water Board of New Orleans.

Q. Have you prepared a table showing the composition of the Mississippi river water at New Orleans, Louisiana, based upon the chemical and bacteriological data for the months between December, 1900, and August, 1901?

A. I have.

Q. Will you produce and read the table which you have thus prepared?

MR. JEFFRIES: I object to the introduction of the table or to its being read in evidence for the reason that it is incompetent and immaterial and has no bearing upon the issues involved in this case, and for the further reason that it purports to 11194 be a table of averages by months and does not accurately portray or picture or represent the conditions of the water in the river at the point where examinations were made at all times during the term or period of examination, for the reason that it conceals or fails to reveal actual conditions at times.

MR. TODD: Does the objection go to the fact that the daily analyses, or analytical data from which these averages were made was not offered in evidence? I ask this for the reason that if counsel insists I will offer the entire analytical data at the point named in New Orleans, for each day of the examination.

MR. JEFFRIES: My objection principally goes to the competency of the testimony and its relevancy.

A. The caption of the table is "Composition of Mississippi River Water," and the table is as follows:

11195

Composition of Mississippi River Water

(Parts per Million.)

New Orleans, La.

Month. 1901.				Dec.	Jan.	Feb.	Mar.	Apr.	May	Jun.	Jul.	Aug.

11196 Q. Will you explain the table that you have just introduced in evidence and state what it shows in regard to the purification of the Mississippi river at New Orleans?

A. This table shows that the Mississippi river water at New Orleans is a very muddy stream and varies in character more or less with the character of the contributing tributaries.

The temperature may be passed over without comment.

The silica turbidity is a measure of the resistance of the water to the passage of light—in other words, a measure of the muddiness of the water, the higher the figures the higher the turbidity.

The color is the color of the dissolved matter after the suspended matter is removed. In general it is inappreciable and would not be noticed by the ordinary observer.

The oxygen consumed is a measure of the carbonaceous organic matter in the water and in the case of this water means that the suspended matter contains large amounts of organic matter from swamps which matter had been absorbed by the clay particles.

11197 The nitrogen as albuminoid ammonia shows that leaving the suspended matter out of consideration the water is of exceptional quality.

The nitrogen as nitrates and nitrites in this case are evidences of the transformation of the suspended woody fiber and organic matter which is poured into the Mississippi river water from its own central valley by means of such streams as the Yazoo and which in general course down the valley becomes removed to a great extent, into mineral and gaseous matter.

The chlorine in the water is not due in any appreciable degree to the effect of pollution on the watersheds, but probably to salt deposits.

Stearns, in the report for the Massachusetts Board of Health in 1890, states that 20 people per square miles will increase the chlorine content 0.1 part per million. The Mississippi river basin above New Orleans has about 7.3 people per square mile, equivalent to an increase in the chlorine content of about 0.04 of 1 part of 1,000,000. This is within the limits of accuracy of analytical work. The chlorine at New Orleans is indicative of salt deposits which are situated along the contributing tributaries, especially the southwestern tributaries.

Incrusting constituents and alkalinity are of no sanitary significance, they being harmless mineral matter.

The analyses show that apart from the nitrogen as nitrates and nitrites, that the water is a characteristic of the
11198 non-polluted water of this region. An abundance of oxygen is always present in the water, showing that the organic matter has been decomposed to about the limits, the number of bacteria are very low and are chiefly associated with the suspended matter. When the suspended matter is removed, the water is of excellent quality.

MR. JEFFRIES: I move to strike out the last answer for the same reason contained in my objection to the table.

Q. In the bacterial determinations of the water at New Orleans did you make any coli determinations during the course of this invstigation?

A. Tests were made during the flood season, that is from December, 1900, to April, 1901. These tests were made six times a week in December and the number of tests was gradually decreased in 1901 until April, 1901, when the tests were discontinued. Volumes varying from 1 cc. to 300 cc. were employed.

Q. Will you state in detail the results of these tests for coli?

MR. JEFFRIES: Objected to as immaterial.

11199 A. Bacillus coli was only found on three occasions during the five months of the tests. It was found during the first week of December, 1900. It was not found subsequent to that date. When the bacilli were found in 1900 they were found in a small volume of water, namely 1 cc. They were not found subsequent to the first week in December. The presence of these organisms in the water at this time and not at any other times is explained by the fact that on the bank of the river immediately above the intake of the water purification station a number of house boat men and squatters were quartered. During the low water season these people had thrown their feces on the bank of the river, and during the rise it is easy to account for the presence of bacillus coli in the intake of the water purification station at that time, especially so because the intake was located near the bank of the stream and was suspended from a house boat, but in comparatively shallow water.

Q. About how many coli determinations were made during this investigation?

A. 100.

Q. Covering a period of how long?

A. Five months.

11200 Q. How many times was the coli present in this 100 determinations

A. Three.

Q. What conclusion did you arrive at from the results of these coli determinations?

A. That no unpurified sewage was present in the Mississippi river at New Orleans.

Q. Have you figured out the time flow of water from Baton Rouge to New Orleans?

A. I have. Assuming the velocity of the stream at 4 miles an hour, which is neither the maximum nor the minimum, the sewage from Baton Rouge would reach New Orleans in 33 hours after it was discharged into the Mississippi river.

Q. Are you acquainted with the flow of the water at New Orleans?

A. I am.

Q. What is the velocity of the river at that point?

A. It may be taken as four miles per hour.

Q. From what you know of the Mississippi river, what in your opinion would be a fair average of velocity for that river from Cairo to New Orleans?

A. About four miles per hour. Certainly no more.

11201 Q. Have you figured out the discharge of the Mississippi at New Orleans?

A. I have not figured it out. I have it from the report of the Mississippi River Commission. The estimated discharge of the Mississippi River is as follows, taken from the report of the Mississippi River Commission, 1900, on page 18, of the report for Water Purification Investigation, and on plans proposed for sewage and water works system, published by the Sewage and Water Board, New Orleans, Louisiana, 1903.

Maximum 1,353,000 cubic feet per second.
Minimum 191,000 cubic feet per second.
Average about 685,000 cubic feet per second.

Q. The methods as pursued in your chemical analyses of the waters at New Orleans, and the technique employed in the bacteriological determinations and coli determinations are what are known as the standard methods used by the Massachusetts Board of Health and employed by the different chemists and bacteriologists that have testified in this case?

A. Substantially so, yes sir.

Q. Have you prepared a chart, based upon the monthly 11202 averages of the chemical and bacteriological analyses of the Mississippi river water at New Orleans, Louisiana?

A. I have.

Q. Will you produce the chart and make it a part of your testimony?

Mr. Jeffries: Objected to as incompetent, irrelevant and immaterial.

A. The chart is as follows:

R.S.Weston
Sanitary Expert.

14 Beacon St.
Boston, Mass.

11204 Mr. Jeffries: Let the record appear that complainant objects to any and all charts, maps, tables or plats being introduced which are based upon the chemical analysis and determinations by this witness in the waters of the Mississippi River at New Orleans, for the reason that they are incompetent and immaterial and have no bearing upon the issues involved in this case.

Q. Will you explain the chart just introduced and state what it shows?

A. This chart is made for a clearer demonstration of the main results expressed in the table previously presented in evidence. It gives the numbers of bacteria, the nitrogen as albuminoid ammonia, the nitrogen as nitrites and the amount of suspended matter averaged by months for the same period of time as was covered by the data presented previously in evidence.

Q. Have you prepared a chart based upon the computations which you have already introduced in evidence of the relative pollution of the Mississippi River water at various points together with data for determining the same?

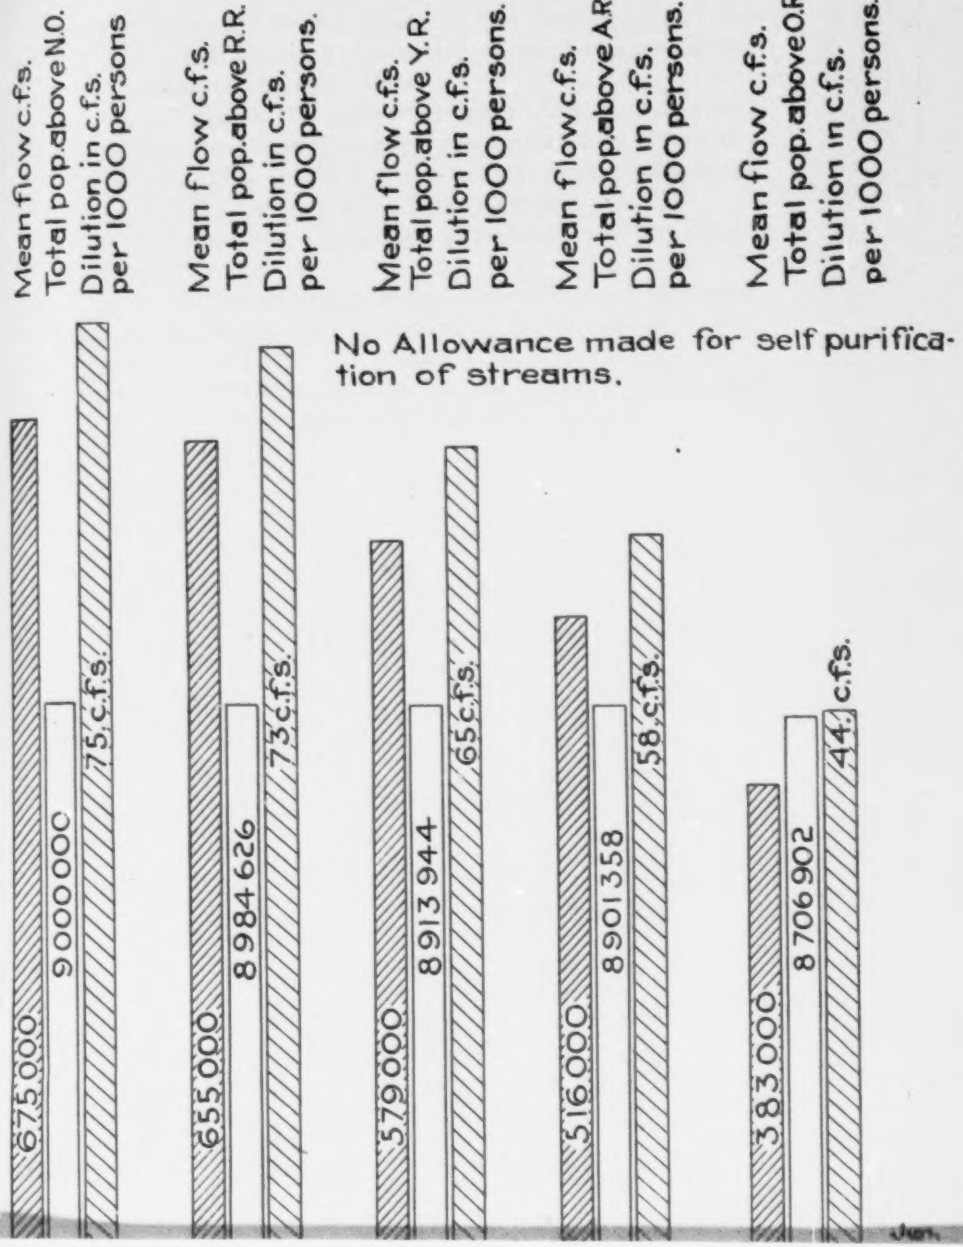
A. I have.

11205 Q. Will you produce and make the data to which you refer a part of your testimony?

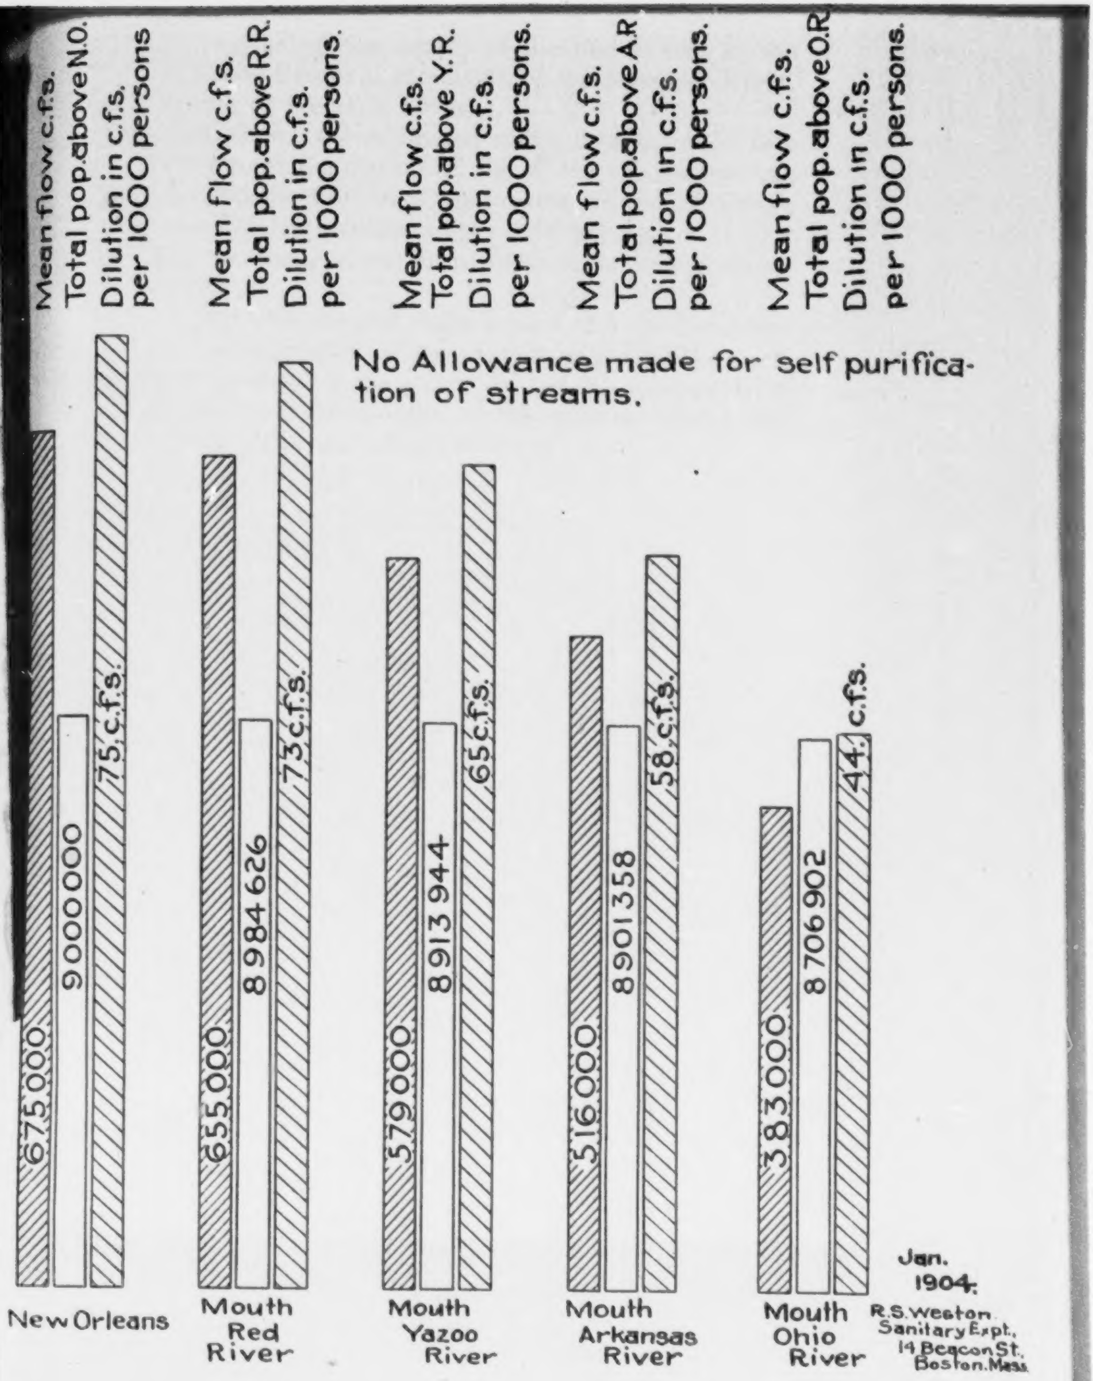
A. The chart entitled "Relative pollution of the Mississippi River Water" is as follows:

Relative Pollution of Mississippi River Water at various points

Together with data for determing the same.



No Allowance made for self purification of streams.



No Allowance made for self purification of streams.

Jan. 1904.

R.S. Weston
Sanitary Expt.
14 Beacon St.
Boston, Mass.

11207 Q. Will you state what that chart is intended to portray?

A. This shows the relative pollution of the Mississippi River water, no allowance being made for self-purification of streams at different points along the course of the stream as follows:

At New Orleans; at the mouth of the Red River; at the mouth of the Yazoo River; at the mouth of the Arkansas River, and at the mouth of the Ohio River.

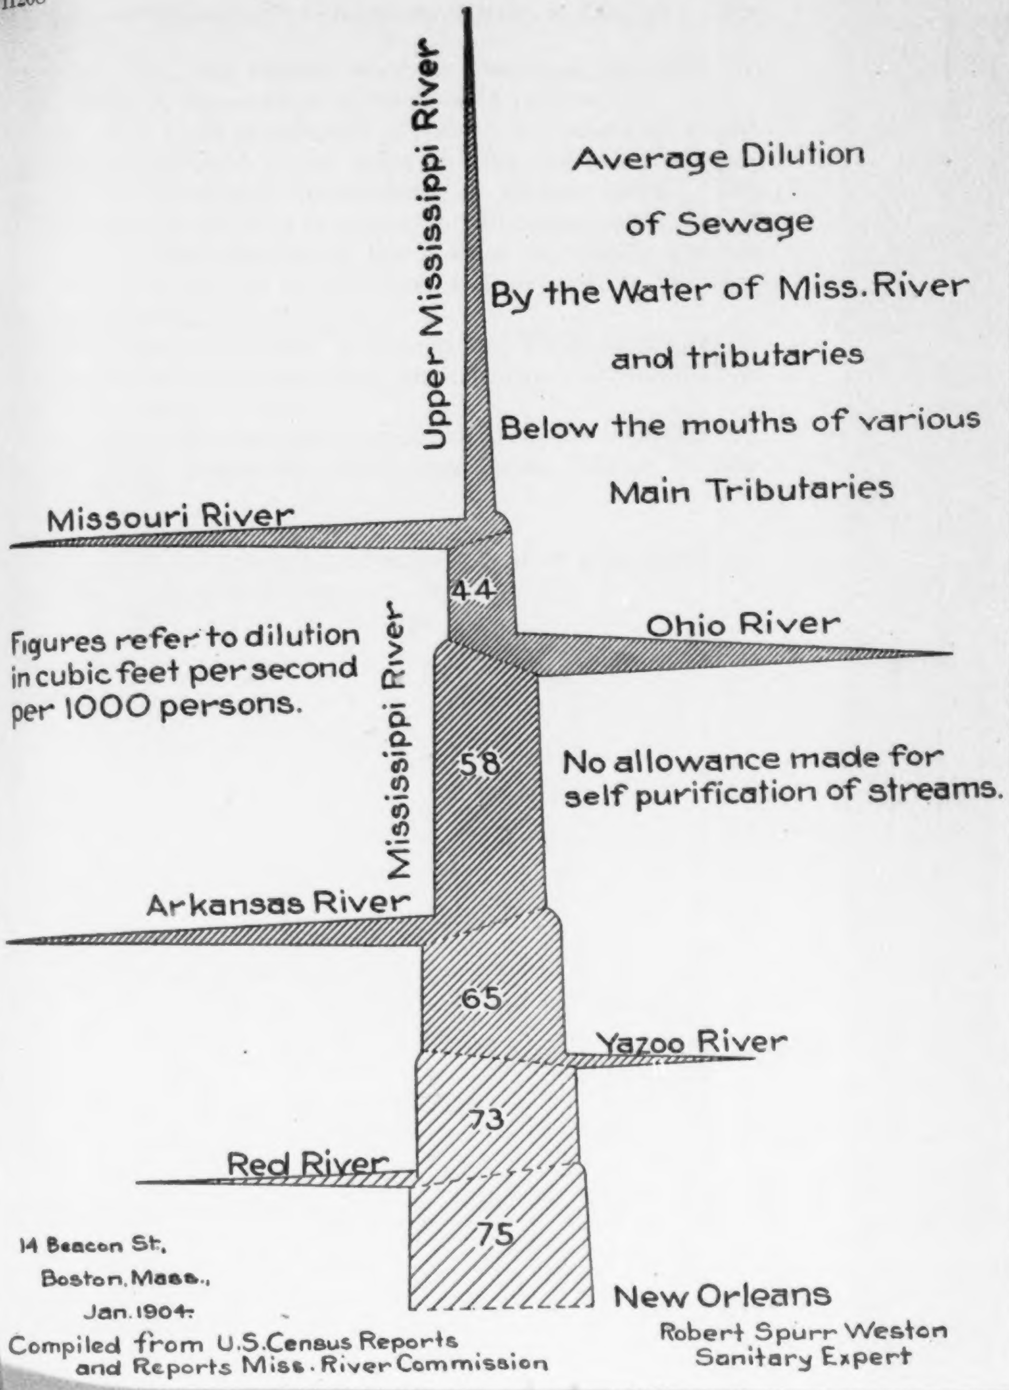
This chart shows the estimated mean flow in cubic feet per second, the total population of the water shed above the various points and the dilution of the present amount of sewage with water in cubic feet per second per 1000 persons.

Q. Have you made a graphical presentation of the same?

A. I have.

Q. Will you produce and make a part of your testimony the graphical representation of the same, based upon the average dilution of sewage by the waters of the Mississippi River and tributaries below the mouths of the various tributaries?

A. I will. The same is as follows:



Average Dilution
of Sewage
By the Water of Miss. River
and tributaries
Below the mouths of various
Main Tributaries
Upper Mississippi River
Missouri River
44
Ohio River
Figures refer to dilution
in cubic feet per second

Compiled from U.S. Census Reports
and Reports Miss. River Commission
Robert Spurr Weston
Sanitary Expert

11209 Q. Will you explain what the chart you have just introduced in evidence is intended to portray?

A. This chart is intended to portray the information just previously submitted in the table showing the relative pollution of the Mississippi River water at various points. The width of the shaded area is roughly proportioned to the flow of the stream. The fineness of the shading is roughly proportioned to the extent of the pollution and inversely to the dilution of the sewage.

This table shows that the Mississippi River as it flows to the Gulf dilutes the sewage more and more as it proceeds on its way to the Gulf.

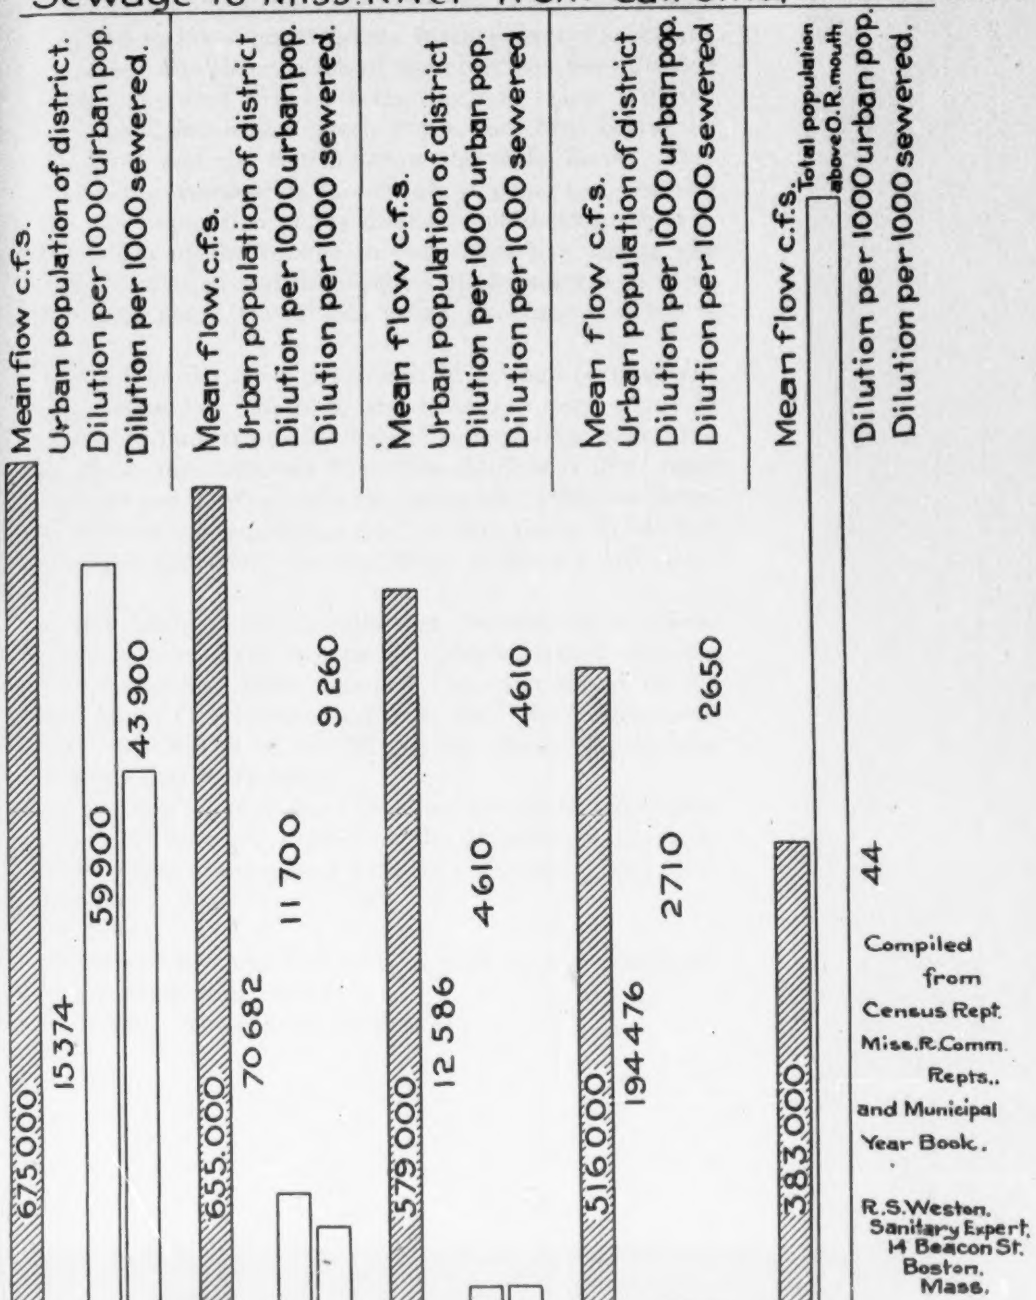
Q. Have you prepared a chart showing the accessions of sewage to the Mississippi River from Cairo, Illinois, to New Orleans?

A. I have.

Q. Will you produce and make a part of your testimony such chart, prepared by you?

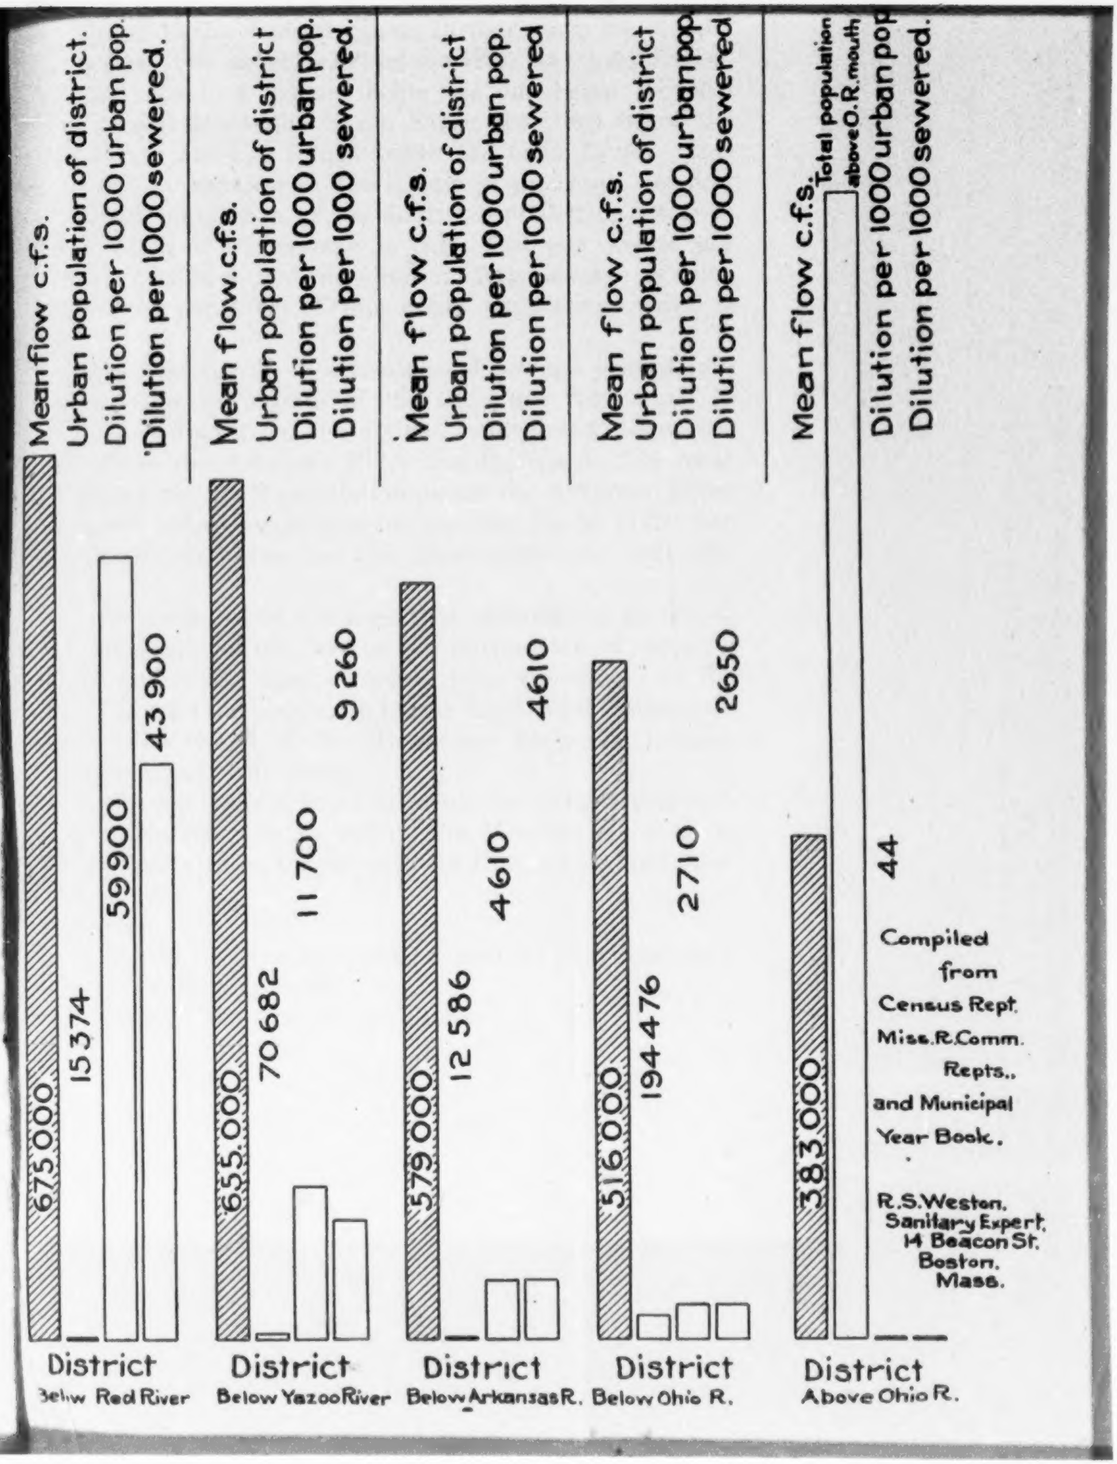
A. The chart is as follows:

Showing Accessions of Sewage to Miss. River from Cairo. Ills., to New Orleans.



Compiled from Census Rept. Miss. R. Comm. Repts., and Municipal Year Book.

R. S. Weston,
Sanitary Expert,
14 Beacon St.
Boston,
Mass.



Compiled from Census Rept. Miss. R. Comm. Repts., and Municipal Year Book.

R. S. Weston, Sanitary Expert, 14 Beacon St. Boston, Mass.

11211 Q. Will you state what that chart is intended to portray?

A. This chart shows the amount of sewage entering the river above the mouth of the Ohio, and the amount of sewage which is added to the river at points further down the stream. For convenience this lower reach of the river has been divided into districts, the first district being the one below the Red River the second below the Yazoo River, the third below the Arkansas River and the fourth below the Ohio River. This table shows the mean flow of the stream in cubic feet per second, the urban population of the district contributing the sewage, the dilution of the sewage in cubic feet per second per 1,000 urban population and the dilution of the sewage in cubic feet per second per 1,000 of this urban population, which is sewered.

It shows that the fresh accessions of sewage poured into the stream below the mouth of the Ohio are very small in amount, namely that from the district immediately below the Ohio and above the Arkansas River the dilution is 2710 cubic feet per second per 1,000 population, below the Arkansas River 4616 per 1000 urban population; below the Yazoo 11700 per 1000 population and below the Red River 59,900 per 1000 population.

11212 In this table as in the ones that preceded it no allowance has been made for the self-purification of streams.

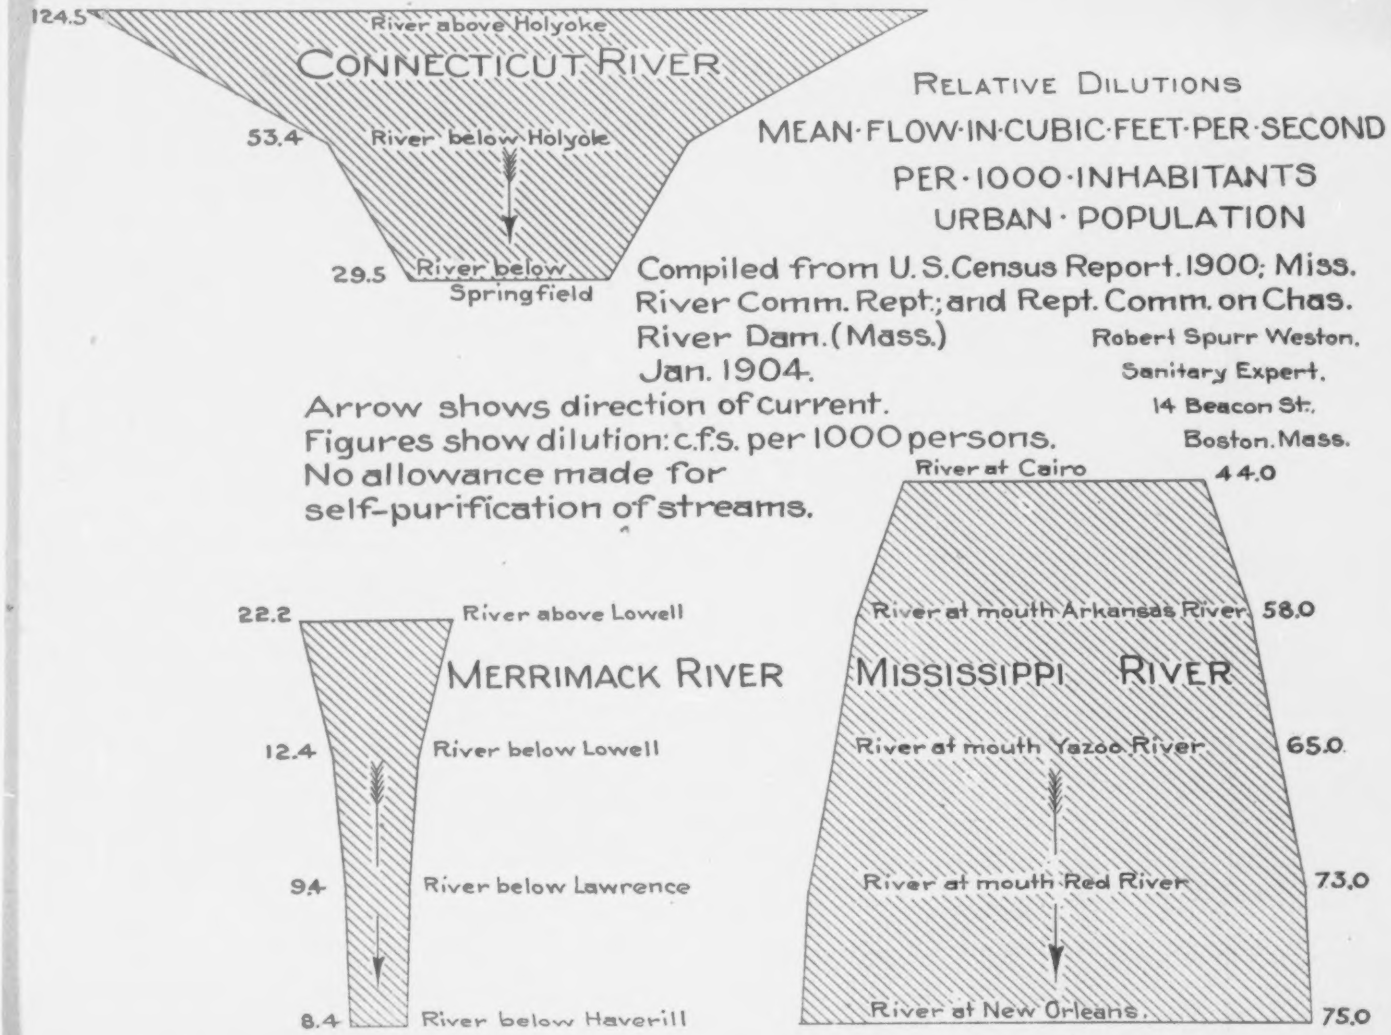
This report has been compiled from the report of the Mississippi River Commission and from the United States census reports—the report of the Mississippi River Commission from the Municipal Year Book.

Q. Have you made a chart showing the relative dilutions of flow in cubic feet per second of the Mississippi River in points of pollution as compared with the Connecticut and Merrimack Rivers?

A. I have.

Q. Will you produce and make a part of your testimony the chart to which you refer?

A. I will. The chart is as follows:



RELATIVE DILUTIONS

MEAN·FLOW·IN·CUBIC·FEET·PER·SECOND
PER·1000·INHABITANTS
URBAN·POPULATION

Compiled from U.S. Census Report. 1900; Miss. River Comm. Rept.; and Rept. Comm. on Chas. River Dam. (Mass.) Jan. 1904.

River at mouth Yazoo River 65.0
River at mouth Red River 73.0
River at New Orleans 75.0

11214 Q. Will you explain the chart which you have just introduced in evidence?

A. This chart is a diagramatic one and illustrates the relative dilutions of the sewage at different points along the Mississippi River below Cairo, at three different points on the Connecticut River as it flows through the state of Massachusetts and at four different points on the Merrimack River as it flows through the same state. The arrows show the direction of the current and the figures to the right and left of the different diagrams show the dilutions in cubic feet per second per 1000 population.

In this case no allowance has been made for the purification of streams.

This diagram was made primarily to contrast the two Massachusetts streams with the Mississippi River. The Massachusetts streams receive so much sewage in the form of fresh accessions below the points of observation that the amount of sewage in the river water as it proceeds down the river within the limits named are always in greater proportion as shown by the observations. While on the other hand as sewage
11215 is carried down the Mississippi River below Cairo it is
always in increasing dilution, the fresh accessions of sewage never being of sufficient amount to maintain the concentration of sewage which existed at Cairo. The reasons for this status of affairs are that the Mississippi River below Cairo is levied and that the population is relatively small. The banks slope back from the river for a greater part of the distance, while in the case of the Connecticut and the Merrimack Rivers the streams flow through a country which is higher than the level of the water in the stream and constant fresh accessions of sewage are received. The litteral population is relatively larger.

Q. From your knowledge of the amount of pollution entering the Mississippi River through its tributaries from the population living upon the water shed, and from the chemical and bacterial and coli determinations, the results of which you have offered in evidence in your testimony, what is your opinion of the condition of the Mississippi River water at New Orleans the point where the investigation was made, as to whether the water of the Mississippi River has become free from the sewage and pollution which it has received by the time it reaches New Orleans?

11216 Mr. Jeffries: Objected to as incompetent, irrelevant and immaterial, having so bearing upon the issues involved in this case.

A. In my opinion there is not the slightest evidence that any unpurified sewage exists in the water at New Orleans apart from that small amount which may occasionally have been washed from the banks of the stream outside of the levies and in the immediate vicinity of the water purification station intake during the time when the tests mentioned in your question were made.

CROSS EXAMINATION

By Mr. Jeffries.

Q. Mr. Weston, what do you mean by unpurified sewage?

A. By unpurified sewage I mean sewage which has not undergone the cycle of changes which would obtain when sewage is mixed with an adequate quantity of water in a running stream, and I mean sewage which has not lost its previous bacteriological character.

Q. What effect has dilution upon the purification of sewage?

A. The main effect of dilution is to furnish an adequate quantity of oxygen for the oxidation of the organic mat-
11217 ter contained in the sewage. This can also be obtained by aerating sewage by passing it over dams, but of course not to the same degree.

Q. The way in which you used the term unpurified sewage in your direct examination had reference to the chemical and bacterial composition of the water in the Mississippi River at New Orleans did it not?

A. I used it in a way which I thought would mean that the analysis gave no evidence of the presence of unpurified sewage in the water at New Orleans.

Q. Even though the city of Baton Rouge is situated 132 miles and within a 33 hour flow from the city of New Orleans any sewage so discharged into the river from Baton Rouge has become purified within the time it reaches New Orleans, within thirty-three hours?

A. Evidently.

Q. And regardless of the fact that pathogenic bacteria may live in diluted water of that character longer than the 33 hours, yet that sewage has become purified and the bacteria do not exist in the water, assuming that it does live that long in the water of that character?

11218 A. The facts are as I have stated them that there are no bacterial evidences of sewage at New Orleans, in spite of the fact that sewage reaches the river.

Q. What was the volume of the water analyzed by you for purposes of ascertaining the presence of the colon?

A. The volumes varied from 1 cc. to 300 cc.

Q. And I understand from your examination that 100 examinations were made?

A. Yes sir.

Q. So there would have been examined in the mean 100 times 150 cc. of water?

A. Yes sir.

Q. How much would that amount to in pints or quarts?

A. Thirty (30) pints.

Q. How many of these experiments were based upon the use of 100 cc. of water?

A. I can not give the exact number.

Q. Approximate it?

A. 85 per cent. 300 cc. of water, not 100 cc.

Q. And you found the colon three times?

A. Three times.

11219 Q. Assuming that these colonies of colon came from the dejecta of a typhoid patient, could you say although they were present that typhoid fever germs were not contained in the water?

A. No.

Q. Do you know what the population of Baton Rouge is?

A. 11,269 in 1900.

Q. What is the population of Natchez?

A. 12,210.

Q. Of Vicksburg?

A. 14,834.

Q. Of Memphis?

A. 102,320.

Q. Of Cairo?

A. Less than 25,000.

Q. Of Louisville?

A. 204,731.

Q. Of St. Louis?

A. 575,238.

Q. Now, is it not a fact that the element of dilution has more to do with the small quantities of bacteria contained in the waters of the Mississippi River at New Orleans than other bacterial or chemical elements known in sanitary science?

11220 A. I do not think so. Because in any other river with which I am acquainted, rivers in which the dilution of sewage in some instances have approximated the dilutions of the sewage at New Orleans by increasing the volume of the samples taken, I have been able in all of these other cases to demonstrate the presence of the bacillus coli communis. At New Orleans I was usually unable to do so. Neither was I able to demonstrate the presence of the bacillus coli communis nor, generally speaking, of any of that gas producing type of bacteria.

Q. Is it not a fact that the larger quantities of chlorine found in the waters of the Mississippi River at New Orleans averaging during the month of December, 1900, 10.2 parts per million, January, 1901, 9.4 parts per million, February, 8.5 parts per million, March, 10. parts per million, April, 7.0 parts per million, May, 9.3 parts per million, June, 14.8 parts per million, July, 8.9 parts per million and August, 8.3 parts per million, when taken together with the maps and charts which you introduced in evidence showing the comparisons between the conditions that existed in the Lower Mississippi and the two Massachusetts Rivers, that dilution is the most important element entering into the consideration of the chemical and bacterial condition of the water in the Mississippi River at New Orleans?

A. It is not the most important factor. It has an in-
11221 fluence but it may be seen upon an inspection that the Connecticut River, just above Holyoke has a greater dilution than the Mississippi River at Cairo and the dilution of the river passing down from Cairo to New Orleans is approx-

imately as 1 is to 2, a little less than 1 is to 2. The condition of the river above Holyoke is that of a sewage polluted stream. The condition of the river at New Orleans is that of a purified stream.

Q. Is it not a fact that the chart which you introduced in evidence showing the conditions existing upon the Connecticut River and the Merrimack River and the Mississippi River below Cairo show that dilution is the principal element entering into the chemical and bacterial condition of the waters of those rivers?

A. No sir, I do not think the charts show anything of that kind. I think if they do I have not explained them clearly. This chart shows that the amount of sewage entering into the river between Cairo and New Orleans is relatively, that is, in proportion to the amount of water flowing in the stream,
11222 very much less than the amount of sewage which enters into these other streams.

Regarding the chlorine I would say that according to the best authorities a population of 20 people per square mile would raise the chlorine content about .1 of a part per million. This population of the Mississippi valley is about 7.3 per square mile. In other words we would expect an increase in the chlorine of about 7.3-20 or 0.4 of 1 part per million due to population.

Q. Is it not a fact that the amount of pollution, of polluting material discharged into the Connecticut and Merrimack Rivers and the Mississippi River, as shown by your charts in the volume of discharges of those rivers, when compared with the diluting effect reverse the conditions of the Merrimack and the Connecticut Rivers from what the conditions are in the Mississippi River?

A. The dilution of the sewage increases as it proceeds down the Mississippi River from Cairo to New Orleans; the reverse is true in the other two streams at any particular point.

Q. Taking the elements of oxygen, the current, the ammonias, the nitrogenous matters and the chlorine as
11223 shown by your table of averages in the composition of the Mississippi River water at New Orleans for the month of December, 1900, and January, February, March, April, May,

June, July and August, 1901, do not these constituents show that the water in the Mississippi River at that point is not virgin water?

A. What am I to understand by virgin water?

Q. Does it not show that this water is of a bad ancestry?

Mr. Todd: I object to the question for the reason that it is indefinite, unscientific and contains terms that are misleading.

A. I can not answer this question directly because I do not understand the exact meaning in this connection of the word "bad." Undoubtedly the analyses show that at some previous time the water had received some organic matter and that this organic matter had become changed since its introduction.

Q. Does not this table showing the composition of the Mississippi River water at New Orleans, which you have introduced in evidence, represent a plea of repentance for that water?

A. I do not understand the question.

11224 Q. Mr. Weston, is it not a fact that this table of analyses bears all the evidence of a prior sewage pollution of that water?

A. To a degree.

Q. Is it not a fact that if the chemical and bacterial contents of a volume of water at the point in the Mississippi River where it was examined at New Orleans was concentrated to the same volume of water as existed in the river at Cairo that the chemical constituents which you found in the water at New Orleans would have been greater and larger and more numerous?

A. If the dilution were less the chemical content would be relatively greater to the same degree.

Q. And this relative increase, would that have shown upon a chart made from results of chemical and bacterial determination?

A. Yes sir.

Q. Is it not a fact that the chemical results as shown on the charts or table read in evidence by you, which represents the composition of the Mississippi River water at New Orleans, during the months of December, 1900, and from January to August, 1901, shows conditions less conducive to a puri-

11225 fication of that water during the winter months than in the summer months, and that there is more polluting material in the water of the river at that point during the winter months than in the summer months?

A. The amounts of the constituents which are ordinarily considered as indicative of pollution as a general rule do not seem to vary greatly through the year with the exception of the period immediately preceding and following the first rise of the river after a period of low water. This rise usually occurs in the winter. To that extent the amounts of these constituents are more in the winter than the other times of the year.

It should be said in addition that the amount of suspended matter is the greatest factor influencing the composition of the Mississippi River water at New Orleans as usually determined in other localities. Standards which would apply to the Connecticut River or the upper Mississippi River would not necessarily apply to the Mississippi River water at New Orleans.

11226 Q. Then the increased amounts of chemical constituents contained in the water of the Mississippi River at New Orleans during this investigation in the winter months over the summer months was due to the effect of reduced dilution during the winter months over conditions existing in the summer months, rather than to the effect of the change in the season producing a greater or a less purification of the water?

A. To which chemical constituents do you refer? Some are high in the winter months. Some are lower in the winter months than they are in the summer months of this period.

Q. I am taking the table as a whole together with all of the chemical constituents and the various quantities of the same, and asking you to consider it as a chemist in connection with water sanitation?

A. Due to decreased dilution?

Q. In the winter over conditions in the summer?

A. In the first place dilution of the river in the winter months is greater than it is in the summer. The Mississippi River at New Orleans, as a general rule, has an annual oscillation reaching its height in April and falling again in the
11227 summer. During the low water period there is little suspended matter. In the fall of the year the streams in the

central valley itself with this accompanying low water in the Mississippi River pour in a large amount of highly colored water. This water, usually from unpopulated swampy regions contains a large amount of organic matter which is as a rule immediately absorbed by the suspended matter in the river, therefore increasing the albuminoid ammonia content of the river during the winter especially during the first flood when the suspended matter deposited at the mouths of these contributary streams is poured out in the main river and is carried down with the stream and especially during this same period when the water makes its first rise upon the banks which to a great extent are covered with the drift wood and decomposing vegetation which has followed the previous high water period.

It is not possible for me to establish a relation between the dilution of the river and the amount of organic matter as shown by the analyses, from the fact that at times of high water in one stream we did have in fact a low flow of the Mississippi River at New Orleans and while the amount of constituents which would effect the analyses was proportionately large, the
11228 dilution was proportionately small.

Q. It is a fact then, is it not, that the chemical and bacterial conditions of the water are continually changing on account of flood conditions and weather conditions which produce drains and variations in the volume and velocity of the water?

A. There are slight changes but not so marked changes as on the tributaries of the stream.

Q. And the smaller the volume of water the greater would those changes manifest themselves? Is that not true?

A. Yes sir.

Q. And that condition maintains itself with reference to all rivers and streams comparatively speaking? In other words, these changes that are brought about in the chemical and bacterial condition of the water in a river will be more manifest and vary to a greater degree in a small stream than in a large, long and continuous stream, will they not?

A. They will be more manifest in the tributaries of any stream than in the main stream itself. The volume of water in the latter acts to balance the effects of rises and changes in
11229 the tributary stream to a great degree.

Q. Going back, now, Professor, to this table which was read in evidence in your direct examination, showing the chemical and bacterial pollution of the Mississippi River water at New Orleans, I will ask you if it is not a fact that that table as a whole shows that there is less bacterial and chemical purification going on in that water at low temperature than there is when the water is at high temperature?

A. I am unable to say that the table shows either of these facts.

Q. Is it not a fact that this table does show large quantities of free ammonia and larger quantities of nitrates and nitrites during low temperature than they do during high temperature?

A. Yes sir.

Q. Is it not a fact that the climatic conditions of the territory traversed by what is known as the lower Mississippi is higher in temperature, on an average, from one end of the year to the other, than the upper Mississippi River and its tributaries?

A. Yes sir, that is a fact.

11230 Q. Is it not a fact that during this entire examination bacterially and chemically, the temperature of the water in the Mississippi River at New Orleans on an average was at no time less than 8.1 Centigrade?

A. It was less than 8.1.

Q. The average per month?

A. Monthly average, no sir.

Q. What would 8.1 Centigrade mean expressed in Fahrenheit?

A. About 46 degrees Fahrenheit.

Q. The temperature of the water in the Mississippi River at New Orleans, for the month of February, 1901, averaged what in Fahrenheit?

A. About 46 degrees.

Q. Above or below?

A. Above zero.

Q. During the month of August, 1901, the average was 29.6 Centigrade. What would that be expressed in Fahrenheit?

A. About 86.

Q. Mr. Weston, in making your determinations of the population upon the water shed of the Mississippi River above New Orleans did you take into consideration the population of Denver, Colorado?

11231 A. Yes sir.

Q. Do you know what river Denver is situated upon?

A. The Platte.

Q. Did you take into consideration the cities of Butler and Beaver Falls, Pennsylvania?

A. Yes sir.

Q. In the urban population you took into consideration the population of all towns over the population of 4,000?

A. Yes sir.

Q. And you did that regardless of where they were situated upon what tributaries on the Mississippi River or of the particular tributaries, and regardless of the soil through which the city would flow, or regardless of the manner in which it would be carried away from the city, did you not?

A. Yes sir.

Q. Is it not a fact that a large part of this urban population is contained in small cities of 4,000 and upwards, that are far removed from the main bed of the various tributaries of the Mississippi, although situated upon the water shed of those tributaries?

11232 A. Yes sir.

Q. Is it not a fact that a large number of these small cities are situated so that the sewage discharges, domestic and manufacturing wastes, are discharged into swamps and pools and basins?

A. It is probably true to some extent.

Q. And what is true with reference to urban population is more particularly true of the rural population is it not?

A. I should expect so, certainly.

Q. Is it not a fact that a great quantity of the sewage from the urban population and the rural population is so deposited that it never finds its way into the river upon whose water shed this population is located?

A. The large part of it is deposited in such a way that it never finds its way into the streams of the Mississippi water shed in an unpurified condition. Ultimately all drainage reaches the water course.

Q. Is it not a fact that the major portion of the waste, of the domestic and manufacturing waste of the rural population is so discharged that it passes over and through the earth, soil and sand in such a way that by the time the water therein contained has reached the tributary that it does not approach the condition of sewage?

A. There are no precise data in existence bearing upon
11233 this point. As a general opinion I would say that more
than half the sewage from rural sources is purified before it reaches the stream.

Q. And what is true with the rural population is true to a large extent with a great number of the smaller cities which are unsewered is it not?

A. That depends largely upon the size of the town and the local conditions. Probably all of the greater cities discharge sewage into some water course directly or indirectly. Probably the smaller inland hamlets rarely discharge into streams directly. Between these two extremes it is pretty hard to place the points, which will show the actual conditions of the small cities, but I should say that what is true in the case of rural population is true to a less degree in the case of towns with population varying from 4,000 to 25,000.

Q. Have you made any calculation for the purpose of determining the population residing upon the immediate banks of the tributaries of the Mississippi River above New Orleans as distinguished from the population of those towns that are inland to those tributaries?

A. In Louisiana the whole of the urban population, about
16,000 people, is situated on the river. In Mississippi
11234 27,000 is situated on the river and between 12,000 and
13,000 inland.

Q. That is the urban population upon the water shed of the Mississippi tributary to the Mississippi?

A. In this 13,000 inland population is included the city of Greenville, Mississippi, which because of its non-discharge of sewage in the Mississippi is considered as an inland town. Since the preparation of the above data the city of Greenville has introduced sewers.

Q. Where did you get that information?

A. That was compiled by myself and my assistants.

Q. Have you such data for any other portion of the watershed of the Mississippi river above New Orleans?

A. I am able to give the total urban population in Tennessee only. I can give no comparisons as you wish.

Q. You have never made any such calculation?

A. No, sir.

Q. Is it not a fact that the stream velocity of the lower Mississippi is less than the stream velocity of the upper Mississippi?

A. If I remember correctly, yes, sir.

11235 Q. Do you not know and is it not a fact that the stream velocity of the upper Mississippi from St. Paul to St. Louis is less than three miles per hour?

A. I do not know.

Q. Do you not know that the stream velocity from St. Louis to the mouth of the Mississippi river is less than two miles per hour?

A. I do not know. The stream velocity of the Mississippi river below St. Louis at a time reaches over five miles an hour.

Q. Do you know the average stream velocity of the upper and the lower Mississippi rivers?

A. I do not.

ROBERT SPURR WESTON.

Adjourned until 10:00 a. m., Saturday, March 5, 1904.

11236 10:00 a. m., Saturday, March 5, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

MR. TODD: I desire to offer in evidence a tabulation by the year of typhoid deaths in the cities lying tributary to the Missouri River, in cities lying tributary to the Illinois River, exclusive of Chicago, in cities lying tributary to the Mississippi River, a list by the year of deaths in the cities of Chicago and St. Louis, respectively, these tabulations being made from the certified reports of the Health officer of the different cities; on the Missouri River all towns with the exception of Jefferson

City heretofore offered in evidence by the complainant, and an agreement that such certificate should be considered as evidence without the necessity of more formal proof, have been verified by me and found to be correct, and as to Jefferson City the offer is made subject to the same rebuttal proof on the part of the complainant, that was stipulated in the cities in regard to the testimony offered from the cities which have been verified.

As to the cities on the water shed of the Illinois River the testimony of complainant has been verified by me and is correct.

11237 As to the cities on the Mississippi River the same is true with the exception of the additional cities not offered by complainant but the certificates I possess which are Red Wing Minnesota; Winona, Minnesota; Clinton, Iowa, and Muscatine, Iowa. and to those cities the evidence is subject to rebuttal if the certificates and number of deaths reported by me can be shown to be different, without the necessity of formal proof, which tables I offer in evidence are as follows:

11238 Death Report from Typhoid Fever in Cities lying tributary to the Missouri River.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902

11242 MR. JEFFRIES: I have examined the certificates from these cities obtained by respondent, which were not secured by complainant, and make no objection to the failure of formal proof thereof, and I accept the showing made on those table for those cities as representing correctly the contents of the certificates upon which said tables are based.

I reserve, however, under the previous agreement and under statement of counsel for defendant, in offering the tables in evidence, the right to rebut the report from those cities which have not as yet been introduced in evidence by or examined by complainant.

11243 PROF. W. P. MASON

a witness on behalf of defendant, being duly sworn, testified as follows:

DIRECT EXAMINATION by Mr. Todd:

Q. What is your name?
A. W. P. Mason.
Q. What is your business?

A. I am professor of chemistry in the Rensselaer Polytechnic Institute, Troy, New York.

Q. Please state what institutions of learning you have been connected with?

A. I have been with the faculty of Rensselaer Polytechnic Institute for over twenty years.

Q. In what capacity, Professor?

A. I have been there in the chemical department as Professor of Chemistry and previous to that as Assistant Professor in Chemistry.

Q. Have you made a special study of water analysis?

A. I have.

11244 Q. What branch of sanitary science have you given especial attention to?

A. To the examination of potable water, especially for city supply.

Q. Have you had any experience in the interpretation of chemical analysis of waters?

A. I have; much.

Q. Have you made a special study of sanitary problems?

A. I have made a special study of sanitary problems as related to water supply.

Q. Are you an author of works on water supply and examination of waters?

A. I am.

Q. What works, Professor?

A. "Water Supply," published by John Wiley & Son, and "Examination of Water," published by the same firm.

Q. Have you, as an expert, reported upon and testified in legal cases regarding the water supply of cities or towns of the United States.

A. I have.

Q. Name such cities or towns?

11245 A. New York; Brooklyn; Philadelphia; Washington; Columbia, S. C.; Greenville, S. C.; Danville, Virginia; Birmingham, Alabama; Meridian, Mississippi; Denver, Colorado; Indianapolis, Indiana; Duluth, Minnesota; West Superior, Wisconsin; Buffalo, New York; Elmira, New York; Albany, New

York; Troy, New York; Cohoes, New York; Newark, New Jersey; Newburg, New York; Waterville, Maine; Waterford, New York; Providence, Rhode Island; Bath, Maine; Rennslaer, New York; Erie, Pennsylvania; Hot Springs, Arkansas; Atlantic City, New Jersey; South Hampton, New York; Burlington, Kansas, and sundry others that I can not remember.

Q. Who were the parties in the suits to which you refer?

A. Sometimes these suits were pending between the city and the water company. Sometimes they were between rival filter companies. Sometimes they were investigations in which there were no suits, the city merely wishing to secure the best possible supply and asking advice thereupon.

Q. Were you always on the side of the city or town?

A. Sometimes I was employed by the city as against the water company; sometimes by the water company as against the city.

11246 MR. JEFFRIES: The question and answer are objected to as immaterial.

Q. Have you examined the water supply of any foreign city, if so state what cities they were?

A. I have examined the water supplies of Paris, Hamburg, Copenhagen, London, Liverpool, Hague Stuttgart, Lubeck, Amsterdam and sundry others.

Q. Professor, will you give a brief description of these different European supplies that you have enumerated?

A. In some instances as in that of Paris the supply is partly from the river and partly from springs, the same being piped in double street mains. In some instances as in Hamburg the principal feature of the water plant is the filtration system. I have examined the beds in such places pretty carefully, said beds being upon the English system, commonly called in this country slow sand filtration. In some places the supply has been from deep sources as at Copenhagen, where the water comes from artesian borings. In some instances the water is obtained from surface sources as at Boulogne and is

11247 purified by special devices such as Anderson's process. In some instances as in Naples, the water comes from spring sources, and is chiefly interesting because of the manner in which it is stored. In some instances, as in the water supplies of Spanish cities, which I have not previously referred to, the water supply is principally interesting from the fact that it has been used for a long period of time and is a relic of past civilization.

In some instances, as in the water supply of North Africa, the water is principally interesting in that it represents the renewal of very ancient developments of springs. In the case of the Oasis of Biskra the water supply there is interesting in that it comes from deep sources at the foot of the Atlas Mountains and is conducted to the Oasis and distributed in rather an interesting fashion.

All of these supplies have their own particular points of interest.

Q. Are you acquainted with the literature bearing on typhoid fever epidemics?

A. I am.

11248 Q. Without going into detail you have reference to all the typhoid fever epidemics that are known of in this country?

A. Yes sir, I refer in that answer to both American and foreign typhoid fever epidemics. I am familiar with the literature thereupon.

Q. Have you investigated any typhoid fever epidemics?

A. I have in the instances of water examinations to which I have already testified, some questions involving typhoid fever arose therein, as for instance Bath, Maine; Cohoes, New York; Albany, New York; Buffalo, New York; Waterville, Me., and possibly one or two others. I do not remember which ones now.

Q. Are you acquainted with any epidemics other than typhoid fever epidemics?

A. Yes sir, with those of Asiatic cholera.

Q. What epidemics of Asiatic cholera are you acquainted with?

A. I made more or less of a study of Asiatic cholera in Sicily and Italy, more particularly at Messina.

Q. Was this a personal study?

A. This was a personal study, not during the time of the cholera outbreak. I was not there then but I visited the place in order to obtain the information of an epidemic which was past.

Q. Give the results of your investigation?

A. The investigations resulted in learning of the fact 11249 that cholera was due in that instance to a contaminated water supply, the contamination coming from the washing of infected linen in large water tubs of stone, such infected water afterwards flowing into the mains of the city and being distributed to the people. The facts in the case were that the mains of the city of Messina, Sicily, were pretty badly located and badly laid and opportunity for infiltration of infected water was very great, and as a result cholera broke out in that community. The authorities felt that the water was possibly in fault and they obtained water from the main land and the people were supplied therewith and the cholera epidemic was checked.

Q. Have you examined and studied the bacterial and chemical analyses of the waters of Lake Michigan, the drainage canal, the Desplaines River, the Illinois River, the Mississippi River, and the Missouri River as made by Professors Jordan, Palmer, Gehrmann and Burrill, the same being published in what is known as reports of Streams Examinations, published by the Sanitary District of Chicago?

A. I have.

Q. Are you acquainted with the Chicago River, the drainage canal, the Desplaines River, the Illinois River and 11250 the Mississippi River from Grafton to St. Louis?

A. Yes sir, I am.

Q. What opportunities have you had for becoming acquainted with the water course from Chicago to St. Louis?

A. I went on a boat from the water front to Lockport, down the drainage canal, by day light. I afterwards followed the course of the river in trolley and on train as far as LaSalle and then took a steamer and went from LaSalle in day light to St. Louis, tieing up at night so that no places were passed in the dark. On arrival at St. Louis I visited the settling basins and saw them being cleaned.

Q. Have you made a special study of bacteriology as applied to water investigations?

A. I have.

Q. Are you acquainted with the experiments made with the bacillus prodigiosus by Dr. Ravold?

A. I have read of that experiment. I have read of it in the testimony.

Q. Assume that 107 barrels of 40 gallons each of culture of bacillus prodigiosus, consisting of one hundred million billions to a cubic centimeter, as contained in said barrels,
11251 was deposited in the Chicago drainage canal at the town of Lemont, on the afternoon and evening of the 6th of November, A. D., 1901, during a period of from four to eight hours.

Assume further that immediately after the said barrels were emptied into the drainage canal, the laboratories established at Lockport, Joliet, Peoria, Grafton, on the Illinois River, and the intake tower of the St. Louis water works, chain of rocks, were notified and that samples were collected at each of these places every hour of the day and night for the purpose of bacterial analyses, for the ascertainment of this bacillus prodigiosus, and assume that at Lockport these hourly samples taken day and night were taken from November 7th to November 25th, a period of 18 days, the total number of samples taken being 432.

Assume that at Joliet these hourly samples taken day and night were taken from November 7th to November 25th, a period of eighteen days, the total number of samples taken being 432.

Assume that at Peoria these daily samples, taken day and night, from November 8th to November 30th, a period of 22 days, amounted to a total of 528 samples.

Assume that at Grafton these hourly samples were taken
11252 day and night from November 12th to December 15th, a period of 33 days, the total number amounting to 792, of which 384 were analyzed by Dr. Ravold.

Assume that the total number of samples taken day and night at the chain of rocks were 720.

Assume that at the laboratory tap these hourly samples taken day and night from November 20th to March 1, 1902, a period of 100 days amounted to a total of 2400.

Assume that the total number of samples analyzed at the different points for the periods above mentioned was 5304.

Assume further that on December 4th at 8:45 one bacterium bacillus prodigiosus was found at the intake tower at the chain of rocks.

Assume that on December 5th at 9 A. M. 1 bacillus prodigiosus was found at the intake tower, at chain of rocks.

Assume that on December 8th at midnight, 1 bacillus prodigiosus was found at the intake tower, chain of rocks.

Assume that on December 6th, at 8 A. M., at Grafton, 1 bacillus prodigiosus was found.

Assume that on December 7th at midnight, at Grafton, 1 bacillus prodigiosus was found, and

Assume further that these five organisms were all the 11253 organisms of prodigiosus that were found in the examination made from Lockport to the intake tower at the chain of rocks and the laboratory tap in the city of St. Louis, which were made during the progress of this investigation, as hereinbefore set forth, and at no time was there more than one single bacillus found at each of these places.

Assume all of the facts as hereinbefore stated to be true what is your opinion as to the value of this experiment as indicating the probable longevity of the typhoid bacillus as measured by the longevity of the bacillus prodigiosus and the probability that the typhoid bacillus entering the drainage canal from the sewers of Chicago would ultimately find its way through the Desplaines and Illinois River to the town of Grafton?

A. My opinion is that in view of the large number of the bacillus prodigiosus introduced and the small number found the results of that experiment shows a very considerable death rate of the bacillus prodigiosus and by inference at least as large a death rate of the bacillus of typhoid fever under the same circumstances.

11254 Q. What importance do you attach to the experiments as assumed in the hypothetical question?

A. In my opinion it seems that the importance attached is to show that to the extent that a bacillus prodigiousus represents a bacillus of typhoid fever a very large death rate has been proven as occurring among the bacilli of typhoid fever under those circumstances.

Q. Have you made any special study of the typhoid germ as related to water supply?

A. Yes sir.

Q. Is it related to the colon bacillus and if so in what way?

A. Yes sir, it is quite closely related to the colon bacillus. It has even been mistaken for the latter germ. There is some considerable difficulty in distinguishing between them. The appearance of the germs being somewhat similar, although their flagella are not equally distributed, it is necessary in order to distinguish as between them to make use of differentiation tests.

Q. Please give the longevity of the typhoid bacillus in the human body?

A. Typhoid bacillus may remain a long period in the human body, at least months.

11255 Q. In soil?

A. The bacillus of typhoid fever may remain alive in soil for a period of at least weeks and possibly months.

Q. In water?

A. The question of the longevity of typhoid fever in water may be best stated by saying that it dies out in water more or less quickly en masse, although some individual cells, being more resistant may remain alive for a longer period. I should say that it would be right to limit it to a very much shorter period of time, that is it should be measured by days in water.

Q. Does the character of the water affect the longevity?

A. Yes sir. In the case of a relatively pure water the longevity of typhoid bacillus is greater than in one where it has to fight for existence with saprophytic bacteria.

Q. Does the typhoid bacillus multiply and increase in nature?

A. It does not increase in nature outside of the human body although it may live saprophytically for a greater or longer period of time according to its surroundings. It will multiply rapidly in milk, most milk epidemics having been caused by such multiplication.

11256 Q. Do you know of any milk epidemics?

A. Yes sir.

Q. What are they?

A. Stamford, Connecticut. There are a good many milk epidemics from British sources that have been reported by Harte.

Q. Are conditions of the laboratory experiments more or less favorable than conditions in nature for the longevity of the typhoid bacillus?

A. The laboratory conditions are more favorable for the longevity of the typhoid bacillus.

Q. If more favorable, state what reasons you have for your opinion?

A. The vessels in which the experiments are performed for some reason seem to give conditions favorable to its life, those vessels usually being small vessels of glass but where the conditions resemble more closely those of nature, as for instance where a large tank is employed, the length of the life of the bacillus coli and of the bacillus of typhoid does not seem to be so great. I would quote in support of that some experiments that have been recently made upon thè bacillus coli communis by the Massachusetts Board of Health where the vessel containing the germs, suspended in the Merrimack River water, 11257 was a large one, about 12 feet deep. The reference that I can give you is the report of the Massachusetts Board of Health for 1902, pages 259 and 260. Under those circumstances it was found that the longevity of the colon bacillus was limited to 11 days. It was not found in the tank after that period.

Q. Will the germ of typhoid fever live as long in polluted water as in pure sterilized water?

A. No.

Q. How do you account for this?

A. In the case of polluted water it has to struggle for its existence amid adverse germs in great numbers and it is overgrown.

Q. What do you mean by over-grown?

A. Well, the conditions of its existence are such as to cause it to struggle in the presence of bacteria different from itself, which bacteria are in larger numbers and are producing toxins which are capable of interfering with its growth.

Q. From your knowledge of the quality of water in the drainage canal, the Desplaines River and the Illinois River, what is your opinion as to the longevity of the typhoid bacillus in those waters?

Mr. Jeffries: I assume that the witness is basing his
11258 answer only upon the knowledge which he has shown to
possess of the waters of the canal and the river?

Mr. Todd: I object to counsel assuming anything.

Mr. Jeffries: Unless the answer be limited to the qualifications of the witness, stated by him, I object to the question.

A. I believe that the typhoid bacillus would live in the water of that description for a less period of time than in sterilized water or water of greater purity, from a bacteriological standpoint, and that it would be limited in length of life to a question of days.

Q. How do you account for your assumption that the life of the typhoid in the waters of the drainage canal, the Desplaines and Illinois Rivers is shorter as compared with its longevity in laboratory experiments?

A. I have already touched upon that question, and I base my opinion upon the fact that where the experiment has been upon a large scale, as in the instance in the Massachusetts Report, quoted, we get a shorter period of time during which the
bacillus will remain alive. In other words as we approach
11259 the conditions of nature the opportunities for its destruction seem to be greater than in the conditions obtaining
in the laboratory experiment.

Q. Are you acquainted with the physical conditions of the drainage canal, the Desplaines River and the Illinois River and the Mississippi River to St. Louis?

A. I am.

Q. Will you describe the dams in the Illinois River?

A. The dams in the Illinois River to my knowledge are but four. I am informed that there is a fifth. I did not see it. At the time of passing down the river the water was of sufficient height to permit the steamer to pass over the top of two of those dams and the two other dams we were locked through but they were all submerged dams.

Q. What effect do these dams have upon the problem of sedimentation?

A. They will increase the opportunity for sedimentation in the river although I do not believe that they will increase it to an extent that amounts to very much, acting more as
11260 riffle boards than dams, they being submerged, sedimentation will take place behind them to an extent, not in the immediate vicinity. But, as I have already said, I do not believe that the amount of improvement obtained through the influence of those dams by sedimentation is very great, although I think it to be something. I state that because I have watched the influence of rifle plates or baffle boards upon tanks in a case at Elmira, where I was running the filter plant, under order of the United States court, in a case between two rival filter companies in a patent suit, and I noticed that the aluminum hydrate did gather behind those boards to an appreciable extent.

Q. How is sedimentation in the Illinois River affected by high and low stages of water?

A. The Illinois River when the water is high overflows its banks and the water settles back to the right and left to a very considerable extent. I noticed that as I went down the river, on a boat, that the trees were standing out in the water, trees apparently growing in one or two feet of water, and such overflow represented a considerable acreage.

The effect of such overflow upon sedimentation will be to spread out the water over a large area thereby giving that
11261 particular part of silt the opportunity of reaching the ground after falling a comparatively short distance. Sedimentation is very marked where the water holding the material to be sedimented is spread out in narrow sheets. Advantage is taken of this fact in the construction of certain forms of sedimentation tanks which tanks are divided by horizontal planes placed quite near each other so that the water has to pass backward and forward between successive pairs of these plates on its way from the top to the bottom. A very considerable amount of purification takes place through sedimentation in a device of that kind because of the short distance of fall for any one sedimenting particle before its resting place is reached.

Q. Will bacteria respond to the law of gravity in pure water of a running stream?

A. Bacteria have weight although not much, and of course like other things of specific gravity greater than the water will tend to fall. Whether they succeed in getting down or not will depend upon the local conditions.

Q. What is it that causes bacteria to settle to the bottom of a flowing stream?

A. If the flowing stream referred to in question be a clear one, gravity alone would operate upon the bacteria and
11262 they would settle therefore slowly.

The settlement might be quite easily interfered with by the currents and the eddies of the stream, but if the stream in question be a turbid one the falling particles causing the turbidity will unquestionably tend to drag down bacteria which may be present by attaching themselves to the bacteria or the bacteria being attached to the falling particles and both going down together. I know that bacteria will settle more quickly in turbid water than in clear because I have tried it and have made a determination of the settlement of such bacteria in both turbid and clear waters, the result being that greater settlement took place in the turbid waters. This is entirely in accord with what we know of the precipitation even of chemical substances because every student of quantitative analysis is aware that when a precipitating solid is falling it tends to drag with it other solids in its immediate vicinity and instances are not unknown, and I can quote, if required, where even soluble material will tend to separate and fall with the precipitating solid to an extent, not completely of course.

11263 Q. Will bacteria settle faster in a turbid water than in one that is clear?

A. That I have just answered in the affirmative. They will.

Q. Could sufficient water from Lake Michigan be carried through the drainage canal (assuming that the maximum amount is 800,000 cubic feet per minute) into the Desplaines river and Illinois river so as to create a condition of purity and clearness that would preclude the operation of sedimentation in the Illinois river?

A. No. There is enough turbidity present in the system of the Illinois river to prevent any such condition obtaining. It is true that I believe that a river will empty itself into the sea in order to clear itself of its turbidity in toto, but there is enough turbidity of a coarser character in all turbid waters which continually falls to the botom to provide neuclei around which sedimentation of bacteria can take place.

Q. Assume that the entire sewage from the city of Chicago should be diverted into the drainage canal and that 800,000 cubic feet of water per minute from Lake Michigan
11264 should pass over the Bear Trap Dam would that amount of dilution be sufficient after it reached the Illinois river, mingled with the sewage of Chicago, to so separate the matter in suspension in the Desplaines and Illinois river as to prevent the operation of sedimentation of bacteria?

A. Under the conditions named the turbidity yet remaining in the Illinois river would be sufficient to permit of the sedimentation of bacteria in the manner already referred to.

Q. What sanitary significance does dilution have in considering the process of the problem of self purification of streams?

A. Simple dilution is purification in that it diminishes the chance of the person drinking the water, assuming the water to be polluted, contracting the disease. Assuming that a glassfull of water should contain 100 typhoid germs, the person drinking it would have a risk to run that we shall describe by the number 100. Should conditions obtain whereby 50 per cent. of all germs in the stream were killed, the person then drinking a glass full of that water would drink 50 germs and his risk would be half of what it was before, namely 50. Should
11265 conditions obtain whereby no bacteria were destroyed but the volume of the stream were doubled by the inflow of pure water, then a person drinking a glass full of the mixture would have in his glass 50 germs and his risk would be 50, therefore the dilution of that water has been productive of just as much purification as the killing of half of the disease germs.

Is the danger of infection really diminished by dilution?

A. Unquestionably it is as per the statement that I have just made.

Q. Is it a fact that the greater the dilution of sewage the less the danger from infection?

A. Surely it is a fact, and again I refer to the illustration I have just given.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois river considered from the standpoint of dilution alone?

11266 MR. JEFFRIES: I object to the question for the reason it cannot be scientifically considered in and of itself alone so far as the application of dilution is concerned in determination of the sanitary condition of the water.

A. The addition of Lake Michigan water to the sewage of Chicago is a benefit to the sanitary condition of the Illinois river considered from the standpoint of dilution alone.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois river considered from the standpoint of chemical and bacterial changes taking place therein?

A. It is a benefit.

Q. If a sufficient volume of Lake Michigan water should be added to the sewage of Chicago so as to cause the elimination in the water of the Desplaines and the Illinois river, what effect would this increased volume of water have upon the question of sedimentation in the Illinois river?

A. If a sufficient volume of Lake Michigan water should be added so as to cause the Illinois river to overflow its banks in the manner I saw it, under those circumstances there would be a greater opportunity for sedimentation because of such overflow, as per the illustration that I have already given. 11267

Q. How do the physical conditions of the Illinois river compare with the other rivers of the country for the purpose of purification or sedimentation?

A. The physical condition of the Illinois river, inasmuch as the river is one which readily overflows its banks, permit of a better opportunity for sedimentation than woudl obtain in a river like the Hudson where no such overflow of the banks is possible, the banks being very much higher.

Q. From your knowledge of the conditions that obtain along the Illinois river, as well as your inspection and consideration of the results of the analysis of the water, both chemical and bacterial, what effect if any does the sewage from Chicago discharged into the drainage canal have upon the waters of the Mississippi river as the same passes along the shore of the State of Misouri?

A. My opinion is that the waters of the Illinois river do not have any appreciable effect, good or bad, upon the waters of the Mississippi river into which it flows.

Q. Professor, from your knowledge of all the conditions that obtain along the Illinois river, as well as your 11268 knowledge of the conditions that obtain in Chicago and the drainage canal, also your knowledge of the water supply of St. Louis, such as is had from the intake tower at the chain of rocks, what effect does the sewage from Chicago have upon the water supply of the city of St. Louis and upon the waters of the Mississippi river as it passes along the shore of the State of Misouri?

A. It has no appreciable sanitary effect, although it is possible it may slightly improve the mixture inasmuch as if there is any difference between the Illinois river at Grafton and the Mississippi river at Grafton and the Missouri river above the junction, that difference is in favor of the Illinois river at Grafton. At the same time I do not think there is very much choice.

Q. What is the behavior of the colon bacillus in soil as compared with that of water?

A. It is of longer life in soil than it is in water.

Q. What in your opinion would be the fate of a typhoid bacillus passing from the sewers of Chicago into the Chicago river and thence into the drainage canal and down the Desplaines and the Illinois rivers?

A. I believe that typhoid bacillus passing, as stated, 11269 would die in the Illinois river, or to put it differently would die before Grafton was reached. I am now speaking about the great mass of them. It is possible that some resistant germs might make the journey, but the great mass of bacilli of typhoid fever would perish before the Mississippi was reached.

Q. Is there such a thing as purification of soil?

A. Yes sir, there is such a thing as purification of soil, although it is a slow process. The best illustration that I can give of that is to refer you to an article by Savage in the Journal of the Sanitary Institute, October, 1903, page 442, in which he refers to the purification of soil and says the "Gradual diminution and disappearance of bacillus coli is of interest from the point of view of specific contamination. It is a more resistant organism than the typhoid bacillus. It is a fair presumption from this that the typhoid bacillus, if present in such soils, would also rapidly die out and that the danger of specific typhoid contamination from building on such made soil can be neglected."

Q. Why is it that the typhoid bacillus will not live as long in polluted water as in pure water?

11270 A. Simply because in polluted water it has to live in the presence of many saprophytic germs which not only monopolize the food supply, but produce toxic products which are poisonous to it.

Q. To what do you attribute the death of the typhoid bacillus in polluted waters?

A. To the adverse conditions set up by the saprophytic bacilli which are present there in large numbers.

Q. What is your opinion as to whether a typhoid bacillus will live longer in the sediment of a polluted stream than it would in the water of the same stream?

A. My opinion is that there would be no material difference between the lengths of time, although the literature on that subject is scanty. I do not know where you would find a record of any examination of a stream noted. There are British statements made that such a bacillus will live in river-mud for a longer period of time than in the water, but they do not seem to be backed up by anything definite. They seem to be unbased statements. Now, on the other hand, the tank experiment which I quoted a little while ago, made by the Massachusetts Board of Health, said tank being a very sizable one, some 10 or

12 feet deep, I have already stated that that tank showed
11271 the death of the bacillus coli in 11 days. At the end of
15 days the water was removed from such tank, proven to have no bacillus coli present and the sediment of that tank was also examined for bacillus coli with likewise negative results.

Q. Will you differentiate between conditions that obtain in moist soil and the sediment of a running stream?

A. The difference is one of water contents. In one case you have only moisture present and in the other you have water present in quantity.

Q. Does the time that a typhoid bacillus will live in moist soil furnish any criteria for its longevity in the sediment of a running stream?

A. I should not expect that the cases would be parallel. That is my opinion.

Q. Are the two conditions comparable?

A. I think not.

Q. Would the fact that a typhoid bacillus lives for several months in moist soil justify the assumption that it would live for the same length of time in the sediment of a river?

A. I should say that it would not justify that assump-
11272 tion and I refer you again to the Massachusetts Board
of Health tank experiment to which I referred. The bacillus coli communis not having been found in that sediment and it being well known that the typhoid bacillus can not stand averse conditions to the same extent as the bacillus coli, if the bacillus coli could not live then the typhoid could not be there.

Q. Do you know of any bacteriologist since the birth of bacteriology that has demonstrated by any experiment that typhoid germs would live in the sediment of lakes or rivers for a long period of time?

A. I do not.

Q. Mr. Fuller, in his testimony on page 4219, in answer to the question, "Is not the length of time that a typhoid bacillus will live in the sediment more a matter of assumption than demonstrated proof?" answered "I consider that it is a very clean cut demonstrated fact that typhoid fever germs may and do and have continued to live in the sediment of running

waters." Q. "For what length of time?" A. "I
11273 would say for a month or more, possibly in cases for years." Q. "Who has demonstrated that it ever lived a year?" answered, "I think that the conditions existing in a moist soil in many rural places of this country where typhoid fever prevails from time to time is proof that typhoid fever germs in the presence of moisture can live for such a time. If that were not so then there would be an elimination of the typhoid fever absolutely through the rural districts of this and other countries." I want to ask you, Professor, whether you know of any demonstration that shows that typhoid fever germs can and do and have continued to live in the sediment of running streams for a period upwards of two years?

MR. JEFFRIES: I object to the question for the reason it is leading, and I move to strike out all that was said in reference to Mr. Fuller's testimony or as to what Mr. Fuller testified to for the reason that the question can be propounded to this witness without stating what Mr. Fuller said and for the further reason that the question is suggestive in that it contains and is a suggestion of counsel to witness that
11274 counsel expects witness to contradict the statement made by Mr. Fuller.

MR. TODD: In reply will state that counsel has a correct appreciation of the question.

MR. JEFFRIES: In answer to counsel's suggestion I renew my objection to the question because the question is suggestive, as explained by counsel who put the question.

MR. TODD: In reply will state that as to whether it is suggestive is a matter for the court. As to the latter part of the counsel's objection he has a correct appreciation of the purpose of the question.

MR. JEFFRIES: I expect to abide by the decision of the court upon the admissibility of the question.

A. I know of no such demonstration.

MR. JEFFRIES: I move to strike out the question and answer for the reason that this witness is not presumed to know the same discoveries in the bacteriological or scientific questions, the same discoveries that are known to Mr. Fuller, or which are and have been lodged in his memory, which may have entirely escaped the notice or observation of this witness.

Q. What is your opinion, based upon all the knowledge which you possess as to whether typhoid bacilli coming
11275 from the sewers of Chicago and entering the drainage canal could survive the journey from Chicago to St. Louis, a distance of 357 miles and be a danger and menance to the inhabitants of St. Louis or to the citizens of Missouri using the water of the Missisippi river in it raw condition for drinking and domestic purposes?

A. My opinion is that typhoid fever bacilli coming from the sewers of Chicago would not be a danger and a menace to the inhabitants of St. Louis using the water of the Mississippi for drinking and domestic purposes.

Q. Where a settling basin holds a sufficient amount of water to supply a city for a period of thirty days and the water is taken out for domestic uses, raw water is immediately substituted from an open river, and typhoid fever should prevail among the people using said water, what is your opinion as to whether such a condition justifies the assumption that because the basin holds a supply of water for the period of thirty days that a typhoil bacillus will live in that water for such a period?

MR. JEFFRIES: Objected to as immaterial.

A. It is my opinion that merely because the capacity of a reservoir is a thirty-day supply, it is not therefore to be
11276 assumed that water remains in that reservoir for thirty days. Much depends upon the construction of the reservoir. Many reservoirs are of stand pipe type, receiving their water and discharging it through the same orifice. Under such circumstances the pumps deliver to the mains and the reservoir merely takes the surplus of the pumpage. During periods of low pumpage the reservoir receives less, hence in reservoirs of that character it is impossible to say how long any particular volume of water may remain therein.

Adjourned until 2:00 p. m., same day.

11277 2:00 P. M., Saturday, March 5, 1904.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. W. P. MASON

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. What does the term epidemiology embrace?

A. The consideration of all those matters dealing with epidemics and vital statistics, matters that deal with a spread of disease among mankind. A general study of epidemics.

Q. Have you examined the typhoid statistics of the Illinois, Missouri and Mississippi water sheds above St. Louis, the same being the table of typhoid statistics which was introduced in evidence in this case just ahead of your testimony?

A. I have.

Q. Have you examined the mortality statistics of the city of St. Louis?

A. I have.

11278 Q. How do you find the mortality statistics of the city of St. Louis in connection with the typhoid statistics on the three water sheds?

A. I notice in the tabulated form of tables reported that for the years 1899, 1900, 1901, 1902 and 1903, the St. Louis deaths are reported as uniformly increasing, being 130, 168, 198, 222 and 288. I notice that Chicago is quite variable.

Beginning with 1899, it is 442 and then dropping instead of increasing, as St. Louis does; 1900 the deaths being 339, rising again for 1901 and 1902 to 509 and 801 and dropping off again in 1903 to 588. I notice, as already stated, that whereas the St. Louis rates uniformly increase, the Chicago rates go up and down in a variable fashion. These statistics are for entire years as given. The relation between Chicago and St. Louis, in the matter of deaths from reported typhoid, would be better given in statistics per month, and I am prepared to show the statistics per month in graphic form, if the counsel so desire.

Q. How does the death rate from typhoid in St. Louis
11279 compare with the death rate from typhoid upon the three water sheds, exclusive of Chicago?

MR. JEFFRIES: I object to the question for the reason that the item of population is not included in the question.

A. I notice that the reported typhoid for 1900 upon the three water sheds, exclusive of Chicago, is 503, which is larger than the preceding year. This is in accord with the reported deaths in St. Louis for that year, the same being larger than the preceding year. It is not in accord with the deaths reported in Chicago, the same being smaller than the preceding year, so that for that one year it would seem that the deaths in St. Louis were not in accord with the water sheds of the three rivers, exclusive of Chicago, that they were with the death rate in Chicago itself, although for the next two years I do not notice that there is the same array of facts, my remarks applying only to 1900.

Q. In the matter of the interpretation of the mortality statistics, what method do you employ?

A. I employ the method of stating typhoid deaths as so many per 100,000 inhabitants.

Q. Why do you employ that method?

11280 A. In my belief that is the more correct method to employ, and it is a very generally employed method. I have at times seen another method employed, and I do not believe that it is a feasible one, namely the percentage of typhoid deaths to total deaths. The reason I do not approve of that method is because, to illustrate, Chicago might have this month much more typhoid than last month, but the total death rate because of some disaster like the Iroquois Theater fire would run up the total deaths so that the typhoid death would apparently improve, whereas really it was worse.

It seems to me that a nearer approach to the truth is obtainable by stating the typhoid rate as so much per one hundred thousand inhabitants.

I can refer you for instance to a recent statement of deaths from typhoid fever in the Engineering News of February 25, 1904, entitled "Cases and Deaths of Typhoid reported at Pittsburg and Alleghany, 1890 to 1903, inclusive." You will observe

that in that table which has been prepared by the Engineering News with the assistance of members of the Board of Health at
Pittsburg that the typhoid is stated in number of deaths
11281 per ten thousand inhabitants. It is also stated as percentage of fatal cases to total cases.

MR. JEFFRIES: I move to strike out all the remarks the witness has made to the Engineering News and particularly to the table cited by him as being contained in the Engineering News, as incompetent and not proper testimony.

Q. Does the percentage of typhoid deaths to total mortality enable the sanitarian to pass judgment upon conditions in a given city as to whether there is an increase or decrease in typhoid fever in such locality?

A. It certainly does not so enable him. Thus, to vary my illustration, should a certain locality have an increase in typhoid, but a very much greater increase in consumption, the report from that place would cause typhoid fever to appear improved whereas it would really be quite the reverse. Typhoid fever would be worse, and consumption would be worse, but the consumption would be at a greater rate.

In other words, you have a comparison between two variables, hence it is difficult to arrive at anything like any
11282 definite opinion thereupon.

MR. JEFFRIES: I move to strike out both the question and answer for the reason that it eliminates the fact that sanitarians in passing judgment upon the increase of typhoid fever on the mortality basis, either on the one hundred thousand per capita basis or on the total death mortality basis, eliminates the proposition that the expert so passing or expressing his judgment may take into consideration the well known fact of which courts take judicial notice as to the population of the particular city being dealt with.

Q. In passing judgment as a sanitarian and epidemiologist upon the mortality percentage basis, what is your opinion as to whether the question of population is involved in that method of calculation?

A. Population is not involved in that. The percentage of typhoid deaths to total deaths.

Q. What method employed by sanitarians takes into account the population figuring out the increase or decrease in a certain community for a given disease?

A. The number of deaths per one hundred thousand method would take it in.

11283 Q. Is the mortality percentage method regarded as the most accurate among sanitarians and students of vital statistics for ascertaining the increase or decrease of a certain disease in a given community?

MR. JEFFRIES: I object to the question for the reason that it shows on its face that under ordinary circumstances and without an absolute increase or decrease in the population there would be very little difference.

MR. TODD: In reply to the objection of the counsel I desire to call the attention of the court to the fact that Professor Sedgwick and Mr. Fuller adopted the mortality percentage method as a correct and proper method for ascertaining whether there was an increase or decrease of typhoid fever in the city of St. Louis since 1900.

A. I will repeat that the percentage method is not the commoner one in use, although it is used, the more common method of stating it being the determination of number of deaths from typhoid per one hundred thousand people.

Q. Is the reporting of non-fatal typhoid cases more general now than it was formerly?

A. Yes sir, it is.

Q. Why?

11284 A. I had occasion to write with reference to that topic to State boards of health of a number of States and I received in reply from them data which showed that there was improvement with reference to the reporting of non-fatal cases of typhoid fever. If the counsel desires I shall be glad to give it much more explicitly.

MR. JEFFRIES: I move to strike out all that the witness has said with reference to the information that he has obtained from the various boards of health, by corresponding, for the reason that it is incompetent.

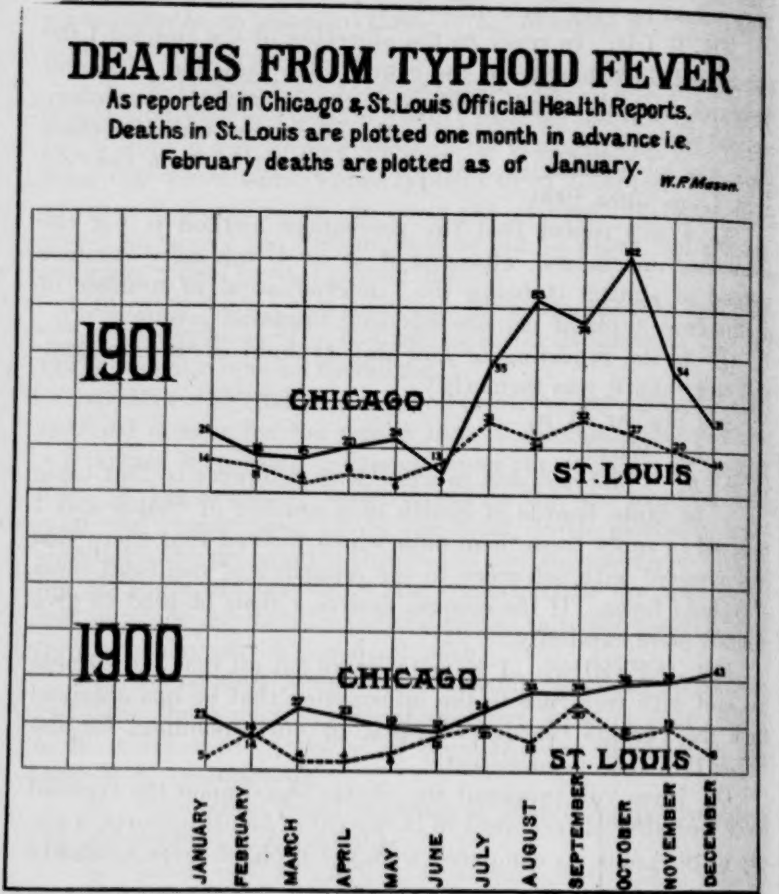
Q. Have you prepared any charts based upon the typhoid fever mortality, as reported in the board of health reports of the city of St. Louis, as compared with the typhoid fever mortality as reported in the Board of Health Report for the city of Chicago by months for 1900 and 1901, and 1902 and 1903?

A. I have prepared those charts.

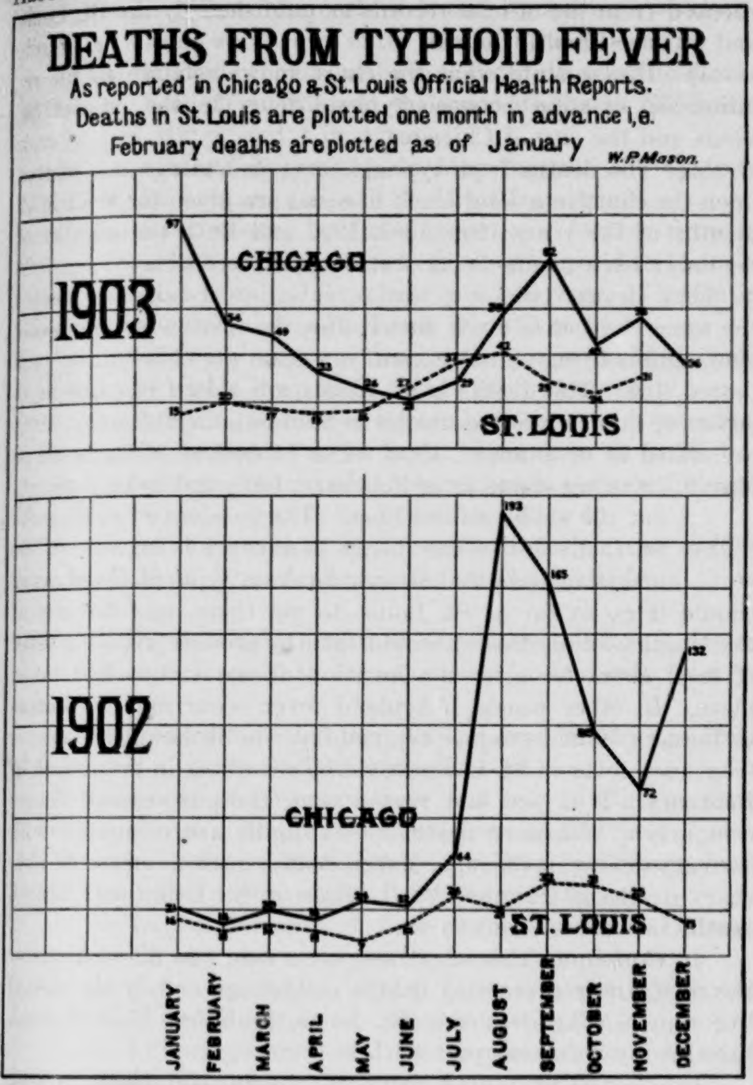
Q. Will you produce the chart for 1900 and 1901, and the one for 1902 and 1903, and make them a part of the evidence?

A. Yes, sir. The caption of these charts is "Deaths from typhoid fever as reported in Chicago and St. Louis official Health Reports." The tables in St. Louis are plotted one month in advance, that is February deaths are plotted as of January.

11285 The charts are as follows:



11286



DEATHS FROM TYPHOID FEVER

As reported in Chicago & St. Louis Official Health Reports.
Deaths in St. Louis are plotted one month in advance i, e.
February deaths are plotted as of January

W. P. Mason.

11287 Q. Will you please state from what data the charts themselves were made?

A. The data from which these charts were made was obtained from Professor Jordan's testimony and afterwards checked from the official records as published by the St. Louis and Chicago Health Boards.

Q. Please state what the chart shows relative to the relationship existing between typhoid fever in the city of St. Louis and the city of Chicago?

A. The deaths from typhoid fever in Chicago are plotted upon the chart in a solid black line and are given for the twelve months of the years 1900, 1901, 1902 and 1903, the number of deaths in each month being stated upon the chart.

The deaths from typhoid fever in St. Louis are plotted the same chart in a black dotted line, the deaths in the successive months being stated in numbers upon the chart along such dotted line. The deaths in St. Louis are stated one month in advance, that is the five deaths in St. Louis in February, 1900, are stated as of January, 1900. The 14 deaths in St. Louis in March, 1900, are stated as of February, 1900, and so on throughout the entire dotted lines. The reason for stating the
11288 St. Louis deaths one month in advance is because of the
length of time that it would take a typhoid fever germ, should it go as far as St. Louis, to get there, and because of the length of time that it would take to produce typhoid fever of fatal character after the invasion of the victim had taken place. In other words, if typhoid fever occurring in Chicago in January should produce typhoid fever in St. Louis, the deaths from such fever in St. Louis would be occurring in the month of February. It is for that reason that, for purposes of future comparison, February deaths in St. Louis are compared with January deaths in Chicago, March deaths in St. Louis with February deaths in Chicago, April deaths in St. Louis with March deaths in Chicago, and so on.

In examining this chart and observing the fluctuations of the solid line representing deaths in Chicago and of the dotted line representing deaths in St. Louis, I observe that the two lines are by no means parallel.

In other words in January, 1900, we have 23 deaths in Chicago corresponding to 5 deaths in St. Louis.

In February, 1900, the Chicago deaths have dropped to 14.

We do not have a corresponding drop in St. Louis. We

11289 have the reverse. We have a rise from 5 to 16.

In the following month of March we have a rise in the deaths in Chicago and a drop in the deaths in St. Louis.

In the following month we have a slight drop in the deaths in Chicago from 27 to 23, and the same deaths in St. Louis, namely 4 in March and 4 in April.

In the next month, namely in May there is a drop from 23 to 19 in Chicago and a rise in St. Louis from 4 to 8.

In the next month, in June, there is a further drop in Chicago from 19 to 17 and a rise in St. Louis from 8 to 15.

In the next month, July, there is a rise from 17 to 26 in Chicago, and also a rise in St. Louis from 15 to 20.

In the following month of August there is a rise in Chicago from 26 to 34 and a drop in St. Louis from 20 to 13.

In the following month of September there is no variation in Chicago, 34 to 34, and a rise in St. Louis from 13 to 30.

In the following month of October there is a rise in Chicago from 34 to 38, and a drop in St. Louis from 30 to 15.

In the following month of November there is a rise in Chicago from 38 to 39 and also a rise in St. Louis from 15 to 19.

11290 In the following month of December there is a rise in Chicago from 39 to 43 and a drop in St. Louis from 19 to 8.

In 1901, there is in January, 1901, a drop in Chicago from 43 to 26, and a rise in St. Louis from 8 to 14.

In the month of February there is a drop in Chicago from 26 to 16, and also a drop in St. Louis from 14 to 11.

The next month of March there is a drop in Chicago from 16 to 15 and also a drop in St. Louis from 11 to 4.

In the following month of April there is a rise in Chicago from 15 to 20 and also a rise in St. Louis from 4 to 8.

In the following month of May there is a rise in Chicago from 20 to 24 and a drop in St. Louis from 8 to 6.

In the following month of June there is a drop in Chicago from 24 to 9 and a rise in St. Louis from 6 to 13.

In the following month of July there is a rise in Chicago from 9 to 55 and also a rise in St. Louis from 13 to 31.

In the following month of August there is a rise in Chicago from 55 to 83, which is a large one, and a drop in St.
11291 Louis from 31 to 24.

In the following month of September there is a drop in Chicago from 83 to 74 and a rise in St. Louis from 24 to 32.

In the following month of October there is a rise in Chicago from 74 to 102 and a drop in St. Louis from 32 to 27.

In the following month of November there is a drop in Chicago to 54 and also a drop in St. Louis, 27 to 20.

In the following month of December there is a drop in Chicago from 54 to 31 and also a drop in St. Louis from 24 to 14.

For the year 1902, for the month of January, 1902, there has been a drop in Chicago from 31 to 21 and a rise in St. Louis from 14 to 16.

For the month of February there has been a drop in Chicago from 21 to 14 and also a drop in St. Louis from 16 to 11.

In the month of March there has been a rise in Chicago from 14 to 20 and also a rise in St. Louis from 11 to 14.

For the month of April there has been a drop in Chicago
11292 from 20 to 16 and also a drop in St. Louis from 14 to 11.

For the month of May there has been a drop in Chicago from 16 to 24 and a drop in St. Louis from 11 to 7.

For the month of June there has been a drop in Chicago from 24 to 22 and a rise in St. Louis from 7 to 14.

For the month of July there has been a rise in Chicago from 22 to 44, and also a rise in St. Louis from 14 to 26.

For the month of August there has been a great rise in Chicago from 44 to 193 and there has been a drop in St. Louis from 26 to 21.

For the month of September there has been a drop in Chicago from 193 to 165 and a rise in St. Louis from 21 to 32.

For the month of October there has been a decided drop in Chicago, from 165 to 98, and a drop also in St. Louis from 32 to 31.

In the month of November there has been a drop in Chicago from 98 to 72 and also a drop in St. Louis from 31 to 25.

In the month of December there has been a rise in Chicago from 72 to 132 and a drop in St. Louis from 25 to 15.

For the year 1903. For the month of January there has
11293 been a drop in Chicago from 132 to 97 and no variation in St. Louis.

For the month of February there has been a drop in Chicago from 97 to 54 and a rise in St. Louis from 15 to 20.

For the month of March there has been a drop in Chicago from 54 to 49, and also a drop in St. Louis from 20 to 17.

For the month of April there has been a drop in Chicago from 49 to 33 and also a drop in St. Louis from 17 to 15.

For the month of May there has been a drop in Chicago from 33 to 26, and a rise in St. Louis from 15 to 16.

For the month of June there has been a drop in Chicago from 26 to 21, and a rise in St. Louis from 16 to 27.

For the month of July there has been a rise in Chicago from 21 to 29 and also a rise in St. Louis from 27 to 37.

For the month of August there has been a rise in Chicago from 29 to 50 and also a rise in St. Louis from 37 to 42.

For the month of September there has been a rise in Chicago from 59 to 82 and a drop in St. Louis from 42 to 29.

For the month of October there has been a drop in Chicago from 82 to 45 and a drop also in St. Louis from 29 to 24.

11294 For the month of November there has been a rise in Chicago from 45 to 56 and also a rise in St. Louis from 24 to 31.

For the month of December there has been a drop in Chicago from 56 to 36, and for St. Louis I have no data because everything has been shoved one month in advance and consequently I am short of data for the month of December for St. Louis.

Q. Professor, from your examination of the monthly mortality from typhoid fever in the city of St. Louis and in the city of Chicago for the years 1900, 1901, 1902 and 1903, what conclusion do you draw as a sanitarian and epidemiologist as to the cause of typhoid fever conditions in the city of St. Louis being attributable to typhoid conditions that exist in the city of Chicago?

A. From an examination of the charts just presented I am of the opinion that no relation whatever exists between the typhoid fever as represented in Chicago and as represented in the city of St. Louis. In other words I am strongly convinced that typhoid in St. Louis is not produced by typhoid fever in Chicago.

11295 It will be seen from an examination of those charts that the curves of typhoid fever are far from being parallel for the two cities. In many instances the rise of the curve from Chicago is coincident with the falling of the curve for St. Louis, particularly so for the month of August, 1902, when the typhoid in Chicago grows from 44 to 193 and the typhoid in St. Louis drops from 26 to 21.

Q. Have you prepared a chart of coli determinations based upon Professor Jordan's tables of coli determinations, made for the year 1901, and introduced by him, and presented and sworn to by him as evidence in this case?

A. I have.

Q. Will you produce the chart thus prepared and make it a part of your testimony?

A. The caption of this chart is "Chart prepared by W. P. Mason based on Professor Jordan's Coli Determinations for 1901," and is as follows:

11296

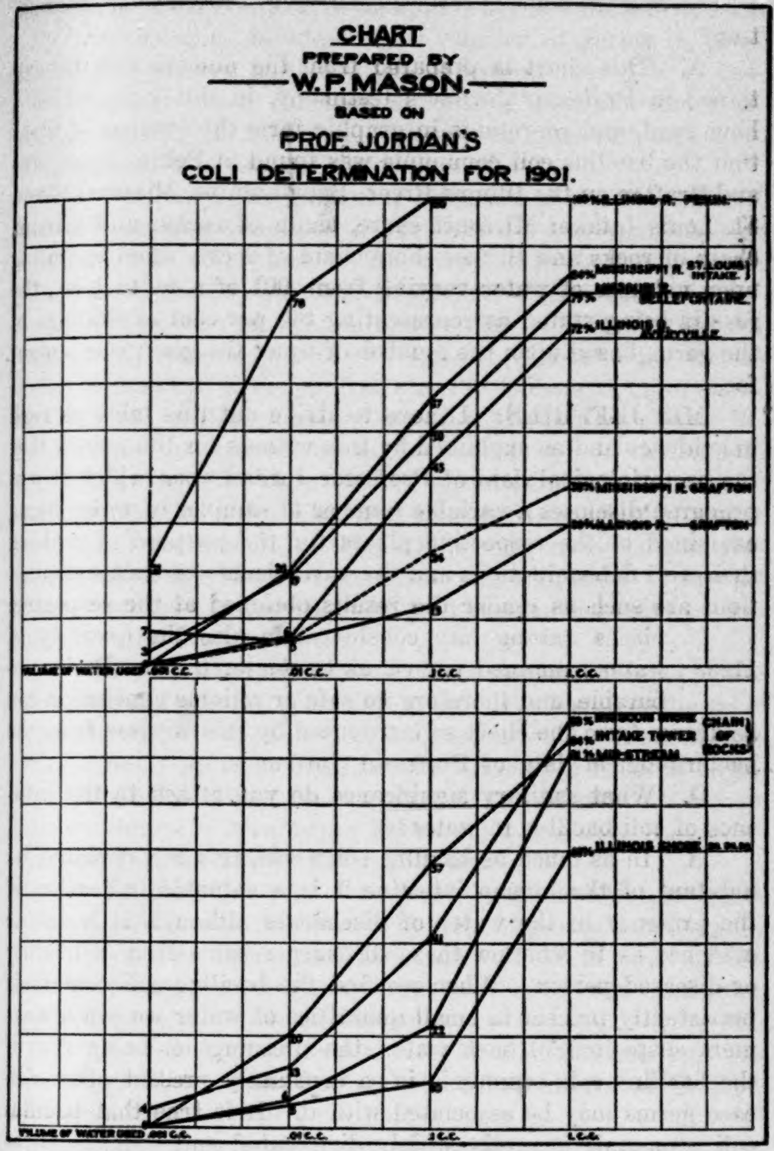


CHART
PREPARED BY
W. P. MASON.
BASED ON
PROF. JORDAN'S
COLI DETERMINATION FOR 1901.

11297 Q. Will you state upon what facts this chart is made and the sources from whence you secured your information?

A. This chart is prepared from the numerical data contained in Professor Jordan's testimony, in this case, which I have read, and represents in graphic form the number of times that the bacillus coli communis was found at Pekin, Averyville and Grafton on the Illinois River; Bellefontaine, Missouri River, St. Louis Intake; Missouri shore, chain of rocks; mid stream, chain of rocks and Illinois shore chain of rocks, when operating upon volumes of water varying from .001 of a cc. to 1 cc., the results being stated as representing the per cent of findings of the germ, based upon the number of times the germ was sought for.

MR. JEFFRIES: I move to strike out this table as read in evidence and as explained by this witness for the reason that the bacteriological data of Professor Jordan upon which it was prepared discloses a variable number of samples of water being examined at the respective places for the purpose of making these coli determinations and the variableness of such examinations are such as render the results obtained at the respective places, taking into consideration also the quantity of 11298 water examined per cc. as to render the results incomparable, and therefore no safe or reliable conclusion can be drawn from the chart so introduced by this witness from the bacteriological data of Professor Jordan.

Q. What sanitary significance do you attach to the presence of coli bacillus in water?

A. In as much as bacillus coli communis is a constant inhabitant of the human intestine it is a valuable indication of the presence in the water of discharges although it bears no evidence as to whether those discharges came from a healthy or diseased person. When we find the bacillus coli communis persistently present in small quantities of water we are always more suspicious of such water, the presumption being that if the bacillus coli communis is so constantly present other disease germs may be associated with it. It is true that bacillus coli communis is pretty widely distributed and that it can be pretty generally found if enough water be examined, therefore we consider it an important matter to have some notion as to the volume of water operated upon in order to obtain from such information an idea of the number of germs in question present in the water. For that reason it is customary to sow different amounts of the water under examination, .001, .01, .1 of a cc., 1 cc. or even more, although 1 cc. is the amount that is usually made use of. 11299

Q. Professor, directing your attention to the chart, based upon the coli determinations of Professor Jordan, what sanitary significance do you attach to that chart as to the comparative pollutions of the Illinois, Mississippi and Missouri Rivers?

A. From an examination of this chart I observe that the bacillus coli communis is more frequently found in the waters of the Mississippi River at Grafton, the Illinois at Averyville, the Missouri at Bellefontaine and the Mississippi at the St. Louis intake and the Illinois at Pekin than it is in the Illinois at Grafton, operating upon 1 cc. of water. Operating upon the same quantity of water I observe that the Mississippi River at the chain of rocks contains the bacillus coli communis most frequently upon the Missouri shore, next in frequency at the intake tower, next in frequency in mid stream and least in frequency on the Illinois shore.

Judging from the bacillus coli communis contents of the several waters, operating upon 1 cc. as stated, the relative purity of the waters in question would stand, first in purity, Illinois River at Grafton. (2) Mississippi River at Grafton. (3) Illinois River at Averyville. (4) Missouri River at Bellefontaine. (5) Mississippi River water at the St. Louis intake, and (6) the Illinois River at Pekin. 11300

Basing upon the same data from the several waters taken at the chain of rocks, the relative degrees of purity would stand, most pure water from the Illinois shore, next in purity from the mid stream, next in purity from the intake tower and least in purity from the Missouri shore.

Q. How does the Missouri river at Bellefontaine and the Mississippi River at Grafton and the Illinois River at Grafton compare as to purity or pollution?

A. Basing my reply upon the bacillus coli communis contents they compare as follows:

The Illinois River at Grafton is the most pure.

The Mississippi River at Grafton is next and the Mis-
11301 souri River at Bellefontaine is the least pure.

Q. What is the liability of pollution and infection of a river coming from the rural population?

A. The source of pollution from a rural population would come from such sewers as it possessed, together with what surface washing might result from its barn yards and from any other source of pollution which there was of surface origin.

Q. Do you know of any typhoid fever epidemics in which infection has come from the rural population?

A. Yes sir. It is very well known that Ithaca typhoid came from such source and Butler, Pennsylvania typhoid from such a source as well. The best known cases are Plymouth and New Haven. The Plymouth and New Haven cases are exceedingly alike.

Q. When considering questions concerning typhoid fever do you regard it as important to note the interval of time elapsing between infection of water supply and the drinking of the infected water?

A. I regard that as very important. That is a topic upon which I have pretty strong opinions and which I have quite an amount of data.

Q. State fully the reasons for your answer?

11302 A. I have made an analysis of 205 British epidemics reported by Harte in a report entitled "Water Born Typhoid made to the Parliamentary Committee of the British Medical Association." A very full report is obtained in that report of Harte's not only of the deaths but of the character of the water supply causing them and I have divided those 205 epidemics into three portions; those that were produced by well water, those that were produced by stream and reservoir water and incidentally those that were produced by milk. Then I had left over some that I could not classify and I have left them out of the count.

In 33 epidemics due to stream and reservoir water I found that the death rate was 9.85 per cent of the cases.

In 75 epidemics due to well water I found that the death rate was 11.83 per cent of the cases, and I found that in 20 epidemics due to milk the death rate was 12.79 of the cases, showing that a well water epidemic was distinctly more serious in character than an epidemic caused by water which had carried the typhoid germ some distance from the point of infection to the point where the water was used for purposes of drinking.

I made an examination of 357 cases of typhoid fever in a typhoid fever epidemic which I examined in Waterville 11303 and I was able there to follow the course more clearly of each case and to get the physician's statement whether the case was a severe one or a mild one. Some of these cases used the city water supply, which was from a contaminated stream. Some of the cases used well water supply and those wells were contaminated. Some of those cases used both sources of water. I found that among the cases that used city water only 41.41 per cent were severe, it not being stated whether they were fatal or not, I rated a fatal case as a severe one naturally.

Among those cases not using city water I found that 61.29 per cent were severe, thus showing that the typhoid fever produced by city water was a milder type, and my explanation of that is that the typhoid germ having to struggle for existence in a river under adverse circumstances, when it arrives at the point where the water is drunk it is not capable of producing so much poisonous material, or in other words not capable of producing so severe a case of fever if it produced one at all.

In the opinion of Mr. George C. Whipple, who testified 11304 in this case, which opinion was given on the witness stand in the case of the Maine Water Company against the city of Waterville. (I was on that case and heard him testify.) He made use of the expression "immediate pollution is very much more dangerous than remote pollution" a view which is entirely in accord with my own views.

Q. Professor, assume that on April 1, 1895, the total number of wells in the city of St. Louis was 4846 and assume that pursuant to an order of the Board of Health of St. Louis, directing the examination of these wells that the city chemist, after an examination of 59 of these wells condemned them as being unsanitary, and assume further that in August, 1895, upon the report of the city chemist condemning 7 more of these wells the board of health of the city of St. Louis passed a resolution to the effect that the city chemist should make no further examination of the wells in question and since 1895 none of these wells has been condemned, what effect would this number of wells in the city of St. Louis have, in your opinion, upon the typhoid conditions existing in the said city, assuming that the water of these wells was used by the inhabitants for drinking and domestic purposes?

11305 MR. JEFFRIES: I move to strike the question out for the reason that the assumptions are not supported by the evidence in the cause.

A. Taking all the assumptions stated in the question I believe that the water of those wells was responsible for a portion of the typhoid fever in St. Louis, because I am a believer in greater danger coming from a polluted well water than from the water of a polluted stream.

Q. What are your reasons for entertaining that belief?

A. My reasons are based upon data such as that which I gave in answer to a previous question, showing that the death rate of well water epidemics was greater than that of stream epidemics, and showing that the intensity of fever from well water epidemics was greater than from stream epidemics.

Such data as I have given I could increase by statistics from Philadelphia, should it be necessary, but the number I have given is already sufficiently large to give accentuation to my opinion.

Q. If the typhoid conditions in part in the city of St. Louis during the last ten years are attributable in part to the
11306 drinking water, and assume that there is typhoid fever existing upon the water shed of the Missouri River water and the Mississippi River water above Grafton, nearer in point of time of flow than the city of Chicago, to what infection would you attribute such proportion of the typhoid in the city of St. Louis as would properly be attributable to its water supply to points having typhoid fever conditions nearer or remote from the St. Louis intake?

A. My opinion is that given points nearer and remote from the St. Louis intake, said points being located upon a water course flowing thereto, and said points all possessing typhoid in their sewer discharges, I would attribute the danger of typhoid fever in St. Louis greater from the nearer points than from those more remote.

Q. Does a sanitary expert call to his attention or assistance all information available from chemical and bacterial sources as well as knowledge of sources of pollution in passing judgment on the sanitary character of a river?

A. A sanitary expert brings to his assistance knowledge of every possible sort that he may possess, bacteriological, chemical and otherwise.

11307 Q. As a sanitary expert, availing yourself of all chemical and bacterial knowledge which is available to you, what is your opinion as to whether a typhoid bacillus lying in the sediment of a polluted stream for a period in excess of sixty days would be able to cause typhoid fever when taken into the human system after it had remained in such sediment for that length of time?

A. I do not think it would produce typhoid fever.

Q. What is your opinion as a sanitary expert as to whether typhoid fever germs coming from the sewage of Chicago through the drainage canal, deposited on the bottom of the Desplaines and Illinois Rivers, between Chicago and Peoria, can remain there for a period of from thirty to sixty days and yet retain their dangerous qualities as well as their pathogenesis?

A. I do not think that they would be able to retain their dangerous qualities after such a discharge in the bottom of the river.

Q. From your personal knowledge of the Illinois River and your knowledge as a sanitary expert, together with all chemical and bacterial knowledge derived from every source, what is your opinion as to whether the sewage from the city of Chicago, passing through the drainage canal into the Illinois 11308 River at different seasons of the year and at different stages of water in the Illinois River would be a danger and a menace to the inhabitants of the State of Missouri and the citizens of the city of St. Louis using the water of the Mississippi?

A. I do not think that it would be a danger and a menace to those people using the water in question.

Q. What is your opinion as a sanitary expert, based upon your examinations of the tables of analysis introduced in evidence by Professors Palmer, Burrill, Gehrmann and Jordan of the waters of the Illinois, Mississippi and Missouri Rivers as represented by such tables which you have examined and are reported in Streams Examinations as to which one of these three rivers from this analysis disclosed the least amount of impurity or pollution?

Mr. Jeffries: Objected to as immaterial.

A. From the data which you have referred to, my opinion is that of the three rivers named the Illinois represents the least impurity although I do not consider that there is any considerable difference between the three, what little difference there is being in favor of the Illinois. I moreover, refer you to the chart which I have in evidence which shows the same result 11309 based upon the colon determination.

Q. If the Illinois River discloses from such data as aforesaid the least amount of impurities, what would be the effect of the waters of the Illinois River emptying into the Mississippi River at Grafton and subsequently uniting with the Missouri River at its mouth upon the combined waters of the Mississippi River at the intake tower at the chain of rocks.

A. The emptying of the Illinois River into the Mississippi River makes no material change in the character of the combined waters. What little change there is is an improvement, but as I have already said the three waters are not widely apart. They are all about the same, any difference being in favor of the Illinois.

Q. Does the mixing of the Illinois with the Mississippi and Missouri Rivers as indicated in the foregoing question create any added danger to the already polluted and contaminated waters of the Missouri and Mississippi Rivers below Grafton?

A. It does not.

Q. As a sanitary expert do you consider the sewage of Chicago entering the drainage canal and the Illinois River which in turn empties into the Mississippi River a menace 11310 and a danger to the inhabitants of the State of Missouri and the citizens of the city of St. Louis taking their water supply from the Mississippi River?

A. It is not a menace and a danger to the people in question.

Q. What is your opinion as a sanitary expert as to whether the germs of typhoid fever could lie in the sediment of the drainage canal or upon the bottom of the Illinois River for a period of from one to three years?

A. I do not think they could and retain their vitality.

Q. Do you know of any instance on record or reference in the literature upon the subject of bacteriology where a typhoid bacillus has lived for a period of from one to three years?

A. I do not.

Q. What is your opinion as to whether a typhoid bacillus deposited on the bottom of the Illinois River could remain there for a period upwards of five years and then stirred up by the action of the waves, the winds, steamboats or by any other means, could continue its journey to St. Louis in a virulent state and be a menace and danger to the inhabitants of the State of Missouri and the citizens of St. Louis using the water of the Mississippi River for drinking and domestic purposes?

A. My opinion is that such a typhoid bacillus could not live for such a period of time and be stirred up as stated, giving the results as stated. 11311

Q. Will you state as a sanitary expert, basing your opinion upon all the information you possess in this case whether the water supply of St. Louis, taken from the intake tower at the chain of rocks, is contaminated by the sewage of Chicago entering the drainage canal and from thence into the Illinois River?

A. My opinion is that it is not contaminated that way.

Q. What effect does an increased volume of water in the Illinois River have upon the low lands lying along the banks of the Illinois River?

A. An increase in the volume of water in the Illinois River floods those low lands. I saw it.

Q. If the increased water at flood tide from the tributaries of the Illinois River as well as the Illinois River itself, exclusive of the waters of the drainage canal, causing a large area of land to be overflowed along the Illinois River Valley, what effect does this overflow have upon sedimentation of the sewage entering the Illinois River through the drainage canal?

A. It increases the opportunity for sedimentation by over flowng those low lands, the principle being entirely simi- 11312 lar to the one which I illustrated in my morning testimony.

Q. Would sedimentation be greater if the volume of water was greater, thereby causing a greater area of territory to be overflowed in the Illinois Valley?

A. It certainly would, for the more acreage that is over flowed by such water the greater number of particles will have a short distance to drop before reaching their final resting place on the soil.

Q. Assume that the five dams which you have described exist in the Illinois River, backing the water up stream for a considerable distance, also there is a lake below Joliet known as Lake Joliet, a lake above Peoria known as Lake Peoria, and many small lakes lying along the Illinois River, receiving water supply from the Illinois River, what effect would these dams and lakes have as sedimentation basins and also what effect would they have in the elimination of the sewage coming from Chicago by way of the drainage canal and the Illinois River?

Mr. Jeffries: Objected to for the reason first that the State of Missouri has no assurance that those dams will be con- 11313 tinued even though they be of any benefit in the way of bringing about the process of sedimentation, and for the further reason that the evidence in this case, taken on behalf of respondents, shows that there is a continuous direct channel from one end of the river to the other during all periods and times of the year since the opening of the drainage canal.

Mr. Todd: I deny the latter part of counsel's objection, unless he means to include the locks as a part of the channel.

Mr. Jeffries: I am relying upon the evidence of respondent's witnesses taken on the river trip.

A. All of those dams and lakes would have an effect in increasing the opportunity for sedimentation, and such increased sedimentation would have a beneficial effect in the elimination and purification of polluted and infected waters coming into the Illinois River from Chicago.

Q. Assume that those dams should be removed at a time when the maximum volume of water was passing through the drainage canal of 800,000 cubic feet per minute, what effect would the removal of those dams have?

A. To the extent the sedimentation of objectionable material would be interfered with, but as I stated this morn-
11314 ing in my testimony I do not think the beneficial effect
of the dams amounts to very much and their removal although it would diminish the purifying power of the stream through sedimentation, such diminution would not be great.

Q. Do you know of any case where dams have improved typhoid rates in cities?

A. Yes sir, there is a recent instance of that in Pittsburg. Pittsburg receives two supplies, one from the Monongahela and the other from the Alleghany. The Monongahela supply is purer water than the Alleghany, and that portion of the city supplied with Monongahela water has a lower typhoid rate than the other. The difference between the two rivers lies in the fact that the Monongahela possesses dams and the Alleghany none, hence the improvement in the typhoid conditions is to be credited to those dams and their opportunities for sedimentation.

Q. Will you state as an expert sanitarian and from all sources of knowledge that you possess whether the water of the Mississippi River at the chain of rocks was prior to January 1900, a safe and potable drinking water, fit for domestic and drinking purposes in its raw state, after passing through
11315 the settling basins?

Mr. Jeffries: Objected to as immaterial.

A. My reply is that it was not.

Q. Was the Missouri River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900, in your opinion?

Mr. Jeffries: Objected to as immaterial.

A. In my opinion it was not.

Q. Was the Illinois River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900, at Grafton?

A. It was not.

Q. Has the sanitary condition of the water of the Illinois River at Grafton been improved or damaged by the opening of the drainage canal?

A. In my opinion it has been improved.

Q. Since the opening of the drainage canal are the waters of the Illinois River at Grafton less sanitary than the waters of the Missouri and Mississippi Rivers?

A. They are not. They are rather better than those other rivers, although as I have said twice before there is very 11316 little difference between them.

Q. What effect does the sewage discharged from the drainage canal have upon the waters of the Mississippi and Missouri River waters, at the chain of rocks?

A. It has no appreciable effect.

Q. Is the water of the Mississippi and Missouri Rivers in your opinion, as a sanitary expert, exclusive of the waters of the Illinois, a safe and suitable water for drinking and domestic purposes, to be used by the citizens of St. Louis in its raw state or treated as now by the city of St. Louis by settling basins?

Mr. Jeffries: Objected to as immaterial.

A. In my opinion the water of the Mississippi and Missouri Rivers, exclusive of the waters of the Illinois, is not a safe and suitable water for use by the citizens of St. Louis in its raw state.

Q. State your opinion as an expert on water supply for cities and towns as to whether or not the waters of the Mississippi River west of the center of the main channel of said river, below the mouth of the Illinois River, and down to the intake tower of the St. Louis water works at the chain of 11317 rocks is less valuable for drinking purposes and more liable to carry water born diseases such as typhoid fever now than it was before the sewage from the sanitary district of Chicago was run into it, from the drainage canal, and through it into the Illinois River?

A. In my opinion it is not less valuable for those purposes.

Q. State whether or not an increase in the speed of the current of the Illinois River by reason of the added volume of water of the drainage canal would affect the amount of sedimentation that might otherwise occur in the Illinois River and if it does affect it, how and in what manner?

A. Under those circumstances as stated, the volume of water in the Illinois River would be increased, thereby causing the river to overflow its banks and submerge the adjacent territory giving the same opportunity for increased sedimentation as under the conditions already testified to.

Q. What effect if any would the increase in the speed of the current in the Illinois River have upon the time within which sewage from Joliet, Peoria and other towns from the Illinois River have if emptied into the waters of the Mississippi
11318 River, if the same are so removed as compared with the conditions which existed at the time it might have taken before the added volume of water from the drainage canal was poured into the waters of the Illinois?

A. So far as particles which were in the main channel were concerned they would doubtless be carried down stream more rapidly; so far as particles which might be contained in the waters which over flowed the low lands were concerned they would not go down so rapidly and there would be a depreciation in the velocity of the current, and there would be an opportunity for sedimentation.

Q. If an increased volume of water in the Illinois by the addition of the water of the drainage canal would make an increased speed in the current of the Illinois River would that increase in said current have any effect in increasing or diminishing the typhoid and liability to typhoid and other water borne diseases on the part of the inhabitants of the State of Missouri using the water of the Mississippi River for drinking purposes below the mouth of the Illinois River?

11319 A. That increase in volume would cause an overflow of the banks and consequently there would be a depreciation in the velocity of the current because of that overflow and that portion of the water which was in the overflow would have low velocity and be given a better opportunity for sedimentation. Some portions of the main channel of the river might or might not have an increased flow in the unit of time, depending very largely upon the amount of water which went over the sides of the river. If the banks were very low as they are in many places, and consequently the river section greatly widened, there would be no material increase in velocity. There might be a decrease. That would have no material influence whatever on the people of the State of Missouri.

Q. Professor Sedgwick, in answer to the question: "What do you say as to the longevity of the germ of typhoid fever as a general proposition in connection with sewage polluted water?" stated among other things: "My belief is that in a sewage polluted stream the typhoid germ might live in gradually diminishing numbers for weeks or months or even years." What is your opinion as to the correctness of that belief, based upon your knowledge as a sanitarian?

11320 A. I do not believe that the typhoid germ would live for such period under those conditions.

Q. Professor Sedgwick, in answer to the following question: "Assuming that the germs of typhoid fever coming from the sewers of Chicago and passing by way of the drainage canal to Lake Peoria be in large numbers deposited in the bed of Lake Peoria for the period of a month, say, do you consider that typhoid germs would be entirely destroyed at the end of that time in that deposit?" answered "No sir." What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago, by way of the drainage canal to Lake Peoria, and be deposited there in the bed of Lake Peoria for the period of a month, and as to whether or not typhoid germs coming from the drainage canal, under conditions as they exist today, would live for the period of a month and not be destroyed before the end of that period?

A. I do not believe that they would live for that period of time under those conditions and I base my opinion very largely upon experiments similar to what I described this morning, the tank experiment which was made by the Massachussets Board of Health, and moreover it is to be remembered 11321 that the burden of proof should be on the part of those who make the statement that the germs will so live.

Q. Professor Sedgwick, in answer to the question, "Assuming that typhoid fever germs coming from Chicago sewers are deposited in large numbers in the lake and slack water portions of the Illinois River above Peoria, do you or do you not consider that flood conditions such as would scour the deposits from the beds of the streams would cause the water leaving Lake Peoria to contain at times more infectious and dangerous pollution than is at present in the diluted sewage entering at the Bear Trap dam at the foot of the drainage canal?" stated "I think at times it might." What is your opinion, taking into consideration all that you know about the conditions of the drainage canal the Desplaines River and the Illinois River, as a sanitary expert and epidemiologist as to whether such a condition at times might exist?

A. I do not believe that such a condition might at times exist. I do not believe that there would be any accumulations of germs taking place gradually, said accumulations afterwards being washed out by flood, and causing wide spread disease in the sections below, and I do not so believe because I observe that we do not have epidemics following floods of that kind. For instance we do not have Spring epidemics of typhoid with us on the Hudson or in the Hudson Valley, although our floods are commonly Spring floods. We have high water resulting from the melting of the northern snows with a great amount of scour following. If the statements above referred to were true there would be deposits of typhoid germs that would gradually accumulate and such deposits would be washed out by these heavy floods and as a result we should have typhod below in the spring time. 11322

We do not seem to have epidemics coming in that order. I can easily understand how you will have typhoid epidemics from the scour such as you have in the Tees river, but that scour is quite different. There you have great deposits of fecal matter in privies and the like in heaps upon the shore, and the high water washes them off from the shore in great masses and the conditions below result in typhoid fever. Such is not a case that is at all comparable with gradual accumulation of river mud, for we know that typhoid will exist for long periods of time in fecal deposits. 11323

Q. What is your opinion based upon all the knowledge which you have of the conditions at Lake Peoria, as a sanitary expert as to whether at any time under any condition the number of typhoid bacilli at that point is even as great as they are at the Bear Trap Dam at the end of the drainage canal?

A. I do not believe they are ever as great as they are at the Bear Trap Dam.

Q. Do you know of any evidence based upon any investigations made by yourself or by any one else that justifies the conclusion that at any time under any conditions there are larger number of typhoid fever germs at Lake Peoria than at the Bear Trap Dam?

A. I do not.

Q. Do you know of any evidence scientifically secured or otherwise that shows that accumulations of typhoid germs are found in lakes or slack water basins of rivers and remain there in storage in vast numbers for any considerable period of time in a virulent state and are suddenly flushed out by freshets so that great numbers of typhoid fever germs are present flowing in a stream a considerable distance from the source of
11324 pollution in greater quantities than exist at the source of pollution?

A. I do not believe that, and for the reasons that I have already stated with reference to the Spring epidemics.

Q. Are you acquainted with the Detroit epidemic?

A. To the extent that I have had information appertaining thereto given me by Professor Williams who has testified in this case. He gave it to me at the time that he was collecting it. I talked the matter over with him and it seemed to me that there might be some doubt with reference to the connection between typhoid fever in Detroit and the dredging of the Black river.

Q. Now, assuming that the only pollution of the river was that contributed to it by the Chicago Drainage canal, and having in mind a large amount of typhoid fever existing in said district, do you or do you not consider the effects of the time interval dilution and sedimentation occurring between Chicago and Grafton would be such as to render the water as it enters the Mississippi River at all times free from the liability of producing water born diseases to the inhabitants of the State of Missouri who use the water for domestic and drinking purposes?

A. I think the water described would not be liable to 11325 produce typhoid fever among those using it.

Q. Assuming that no other pollution or infection enters the river save that which it received from the sanitary district of Chicago, from your knowledge as a chemist and sanitary expert, have you had any experience or knowledge that would lead you to believe that the water of the Illinois River at Grafton is infected with the sewage from Chicago, and if said water enters the Mississippi River, becoming mixed with the latter, would it be a menace to the health of the inhabitants on the Missouri shore of the Mississippi Ricer, using the water for domestic and drinking purposes at points below on the Missouri shore?

A. I have no knowledge of the presence of infected Chicago sewage in the Illinois River at Grafton and I believe that the use of the water of the Mississippi at the chain of rocks, because of the admixture of water from the Illinois River, would not be a menace to the health of the inhabitants of St. Louis.

Q. Is there anything, based upon your knowledge as a chemist and sanitary expert which you know that would lead you to believe that the water coming from the Illinois River at Grafton was infected from the sewage of Chicago, and assuming that the water from the Illinois River, mixed with the 11326 waters of the Mississippi River at Grafton and subsequently mixed with the waters of the Missouri River at its mouth, do you consider the water of the Illinois River thus comingled with the waters of the Mississippi and Missouri Rivers a menace to the health of the inhabitants of the State of Missouri, living upon the Mississippi River using the Mississippi River water for drinking purposes at points below on the Missouri shore?

A. I do not consider that the waters of the Illinois River under the conditions obtaining, comingled with the waters of the Mississippi River are a menace to the inhabitants of the State of Missouri living upon the Mississippi River and using the Mississippi River water for drinking purposes at points on the Missouri shore.

Q. Now, assume that the only pollution upon the water shed of the Mississippi and its tributaries above the intake of the St. Louis water works was that derived from the sanitary district of Chicago, and having in mind a large amount of typhoid fever in Chicago, do you or do you not believe that dangerous infection and dangerous pollution might under existing conditions find its way into the water supply of the city of St. Louis?

A. I do not.

11327 Q. Assuming that there was no typhoid fever pollution upon the water shed of the Mississippi and its tributaries, above the intake of the St. Louis water works, other than that derived from the sanitary district of Chicago, do you or do you not believe that typhoid fever germs from said district are liable to find their way into the water supply of the city of St. Louis through the intake at the chain of rocks, and become a danger and a menace to the inhabitants of the city of St. Louis?

A. I believe that they are not liable to find their way into the water through the intake tower at the chain of rocks and become a danger and a menace to the inhabitants of the city of St. Louis.

Q. Professor Sedgwick, in answer to the question just propounded to you stated: "I believe they are liable to find their way into the intake" and when asked why, answered: "For the reason that typhoid fever having been frequently very abundant in the city of Chicago, I must start with the assumption that a very large number of typhoid germs find their way into the sewage of the city, pass through the sewers and on into the drainage canal, and, subject to local conditions, may, in
11328 diminishing numbers, pass out of the Illinois River,
mingle with the waters of the Mississippi River, pass over to the other side and find their way into the intake at the chain of rocks." Now, Professor, I want to ask you do you know of any evidence, based upon any analysis, experiments or otherwise that justifies the assumption that typhoid fever germs will pass through the sewers and on into the drainage canal and subject to local conditions may, in diminishing numbers, pass out of the Illinois River, mingle with the waters of the Mississippi River and pass over to the other side and find their way into the intake at the chain of rocks of the St. Louis water supply?

Mr. Jeffries: Objected to for the reason it is leading, suggestive, incompetent and irrelevant.

A. I do not know of any analysis or experiments that justify such assumption, but on the contrary I am of the opinion that the charts which I have offered in evidence show that there is no connection between typhoid fever in the city of St. Louis and the city of Chicago, and were it liable that typhoid germs should pass into the water at the intake I should expect that the curves of typhoid fever in St. Louis and in Chicago
11329 would show paralellism whereas they show quite the reverse.

Q. Assuming that an epidemic of Asiatic cholera should occur in the city of Chicago is it possible that the germs of that disease might find their way into the intake tower at the St. Louis water works at the chain of rocks, from the city of Chicago?

A. Germs of Asiatic cholera would be less liable to find their way into the St. Louis water works than germs of typhoid fever for the reason that Asiatic cholera germs are less hardy than germs of typhoid fever.

Q. Now, Professor, considering your personal kuowledge as an expert on sanitary subjects and of typhoid conditions in the sanitary district of Chicago and existing conditions in said district as to sewers and outfalls there and of the amount of sewage under all the existing conditions of the Desplaines, Illinois, Mississippi and Missouri Rivers, and all conditions existing upon the water sheds of said streams and the tributaries thereof, and all existing conditions as to the water supply of the City of St. Louis, and the general sanitary conditions existing in the city of St. Louis, would you or not beyond a reasonable doubt attribute the principal portion of the increase of typhoid
11330 fever in the city of St. Louis, assuming there has been an increase in St. Louis since the opening of the drainage canal, to the infected sewage of the sanitary district of Chicago?

A. On the contrary I would attribute any increase in typhoid fever which might haxe taken place in St. Louis to infection from nearer points because of what I have already testified to as my belief that the nearer the point of infection the greater the danger, and because, further, that the charts which I have offered in evidence shows that there is no relation between the typhoid fever in Chicago and typhoid fever in St. Louis.

Q. Professor, do you consider that the Illinois River water, containing the mixed sewage and canal water from the Chicago sanitary district, since the opening of the drainage canal, has rendered less safe and wholesome now than before the opening of the canal for drinking purposes on the part of the inhabitants of the State of Missouri, the waters of the Mississippi River below the mouth of the Illinois River?

A. I do not.

Q. Now, Professor, I will get you to state whether or not in your opinion the liability to typhoid fever or other 11331 water born diseases on the part of the inhabitants of Missouri using the Mississippi River water for drinking purposes below the mouth of the Illinois River, by reason of the sewage from the drainage canal affecting the waters of the Illinois River is constant, immediate and continuous under all existing conditions upon the Mississippi, the Desplaines, the Illinois and the Missouri Rivers, and the tributaries of said streams, because of the conditions in the water sheds of the said rivers and the tributaries thereof and the drainage canal and the sanitary district of Chicago?

A. Assuming that the question means that the opening of the drainage canal constitutes a constant, immediate and continuous danger under all existing conditions to the inhabitants of St. Louis on the Missouri shore, I shall repeat that in my opinion it does not.

Q. Professor Sedgwick, in answer to a question, among other things, answered: "The mere presence of pollution, I mean by that uninfected sewage, that is supposing Chicago reduced her death rate from typhoid fever, and would still put her sewage down there, that sewage as affecting the lon- 11332 gevity or growth of germs that get in from Peoria or elsewhere would be an added menace to cities with water supply, even if she did not send typhoid fever germs down, sending the filth alone is serious." I will ask you what is your opinion, based upon your experience as a chemist and sanitarian whether the sewage from Chicago favors the longevity or growth of germs from Peoria or anywhere else, emptying their sewage into the Illinois River?

Mr. Jeffries: Objected to as incompetent, leading and suggestive.

A. In reply will state that in my opinion the addition of Chicago sewage as in the question, does not favor growth of the typhoid bacilli introduced at Peoria.

Q. Does the presence of sewage in water add to the longevity and growth of pathogenic bacteria in your opinion?

A. In my opinion it does not.

Q. Do you or not consider that the Illinois River water, polluted and infected by the sewage from Chicago sanitary district, since the opening of the drainage canal, has rendered less safe the water supply of the city of St. Louis as drawn at the intake tower at the chain of rocks, and upon what do you base your opinion?

A. It has not rendered it less safe.

11333 I base my opinion upon the fact that the Illinois River at Grafton furnishes water which is in quality better than it was before the opening of the canal, and better or at least as good as the water of the Mississippi into which it flows.

Q. Assuming that the Chicago sewage from 1,500,000 people living in the sanitary district of Chicago, should be discharged into the Chicago drainage canal and carried through the canal into the Desplaines River and thence into the Illinois River, Chicago being situated 357 miles from the St. Louis intake, and assume that a typhoid epidemic of extraordinary proportions should become prevalent among the residents of the sanitary district at a time when the sewage from said district is being discharged into the canal, what immediate and impending danger would exist and what effect would it have on the people of St. Louis and those people living on the Missouri side of the Mississippi River below Grafton who use the water of the Mississippi River for drinking purposes?

A. It would have no appreciable effect upon them.

Q. Now, Professor, assuming the same conditions as in the last question you have been answering, and assume that instead of an extraordinary typhoid fever epidemic in the sanitary district, a cholera epidemic should prevail in the sanitary 11334 district would the danger be impending and immediate to the people of Missouri below Grafton who use the waters of the Mississippi River for drinking purposes, as far down as the chain of rocks?

A. It would not for the simple reason that the cholera bacillus is less hardy than the typhoid bacillus and what is true with reference to the typhoid dying out is certainly more true with reference to the spirillum of Asiatic cholera.

Q. Taking into consideration all the knowledge which you possess in regard to the bacterial, chemical and physical conditions of the waters of the Illinois River and its tributaries and the river itself and the different towns sewering into the Illinois River and its tributaries, the population upon the water shed of the Illinois River, both rural and urban, the discharge of the river under all conditions and during all seasons, what is your opinion as to the effect of flowing the sewage from Chicago through the drainage canal into the Desplaines and Illinois Rivers, upon the inhabitants of the State of Missouri, using the waters of the Mississippi River for drinking and domestic purposes?

11335 A. It has no materal effect upon the health of the people using the water mentioned for drinking and domestic purposes.

Q. Assuming all the facts in the foregoing hypothetical question, and taking into consideration all the typhoid statistics as they obtain along the water sheds of the Missouri, Mississippi and Illinois Rivers, in the city of Chicago and in the city of St. Louis, and assuming that there is an increase in typhoid fever cases in the city of St. Louis, since January, 1900, as evidenced by the mortality statistics in St. Louis, as disclosed by the Board of Health reports of the city of St. Louis, and taking into consideration all the chemical, bacterial and other knowledge which you possess, what is your opinion as a sanitarian as to whether the increase in typhoid fever as above indicated, assuming that there has been an increase in the city of St. Louis since the opening of the drainage canal can be attributed to the opening of the drainage canal as the direct, immediate and approximate cause of said increase beyond all reasonable doubt

A. I believe that the increase of typhoid fever, if there is an increase of typhoid fever in St. Louis is not due to the opening of the drainage canal.

11336 Q. If the typhoid conditions of the city of St. Louis, since 1900, can not be attributed to the sewage from Chicago, beyond a reasonable doubt, will you please state to what cause it should be attributed, and give your reasons for such an opinion?

A. It should be attributed either to an entirely local cause such as that of well water or milk supply or else to a river carrying infection from points nearer at hand, and the reason that I feel that the points nearer at hand should be held more responsible than those more remote is because of what I have already testified to, namely that the time interval between the point of infection and the point where the water is used is very important.

Adjourned until 10:00 A. M., March 7, 1904.

11337 10.00 a. m., Monday, March 7, 1904. Continuation pursuant to adjournment.

Present, the Commissioner, and same counsel representing respective parties.

PROF. W. P. MASON

resumed the stand for further direct examination, by Mr. Todd, and testified as follows:

Q. Professor, have you had any experience in filter plants and in installation of filter systems for waters in rivers of this country?

A. Yes, sir, I have recommended a good many.

Q. From your knowledge of conditions that obtain at St. Louis do you regard the water at St. Louis as a safe drinking water as it is at present treated with settling basins?

MR. JEFFRIES: Objected to as immaterial.

A. I do not.

Q. How should that water be treated in order to become a safe sanitary drinking water?

A. Sedimentation should be supplemented by filtration.
11338 In this opinion of mine I entirely concur with what has been stated by Messrs. Hazen and Fuller in a report on the water supply for the City of St. Louis, dated 1902, in which Mr. Hazen says, after describing the method of filtration which he proposes, on page 77; "I believe that the hygienic character of the purified water will be entirely satisfactory."

And on the same page: "I believe that the raw water, although polluted far beyond the point where it should be used in its raw state is very much less polluted than many or most of the river waters used by American cities. Purification will remove a very large percentage of the bacteria and the elements of danger in the raw water. So far as there is danger to health in the present water it will be reduced by filtration to an almost inappreciable amount."

Mr. George W. Fuller, in commenting upon Mr. Hazen's statements in this report says, on page 81 of the same report: "With regard to this method of purification for the St. Louis water supply, it is my judgment that it will yield a water of satisfactory appearance and hygienic quality with proper construction and operation of the works and that it
11339 is the best and most applicable method for the conditions existing at and near the chain of rocks."

Q. When was that report gotten out?

MR. JEFFRIES: I move to strike out what the witness read for the reason that the same is incompetent.

A. 1902.

Q. Do you concur in the views expressed by Mr. Fuller and Mr. Hazen, as you have quoted them.

A. I do.

Q. In the installation of a plant for the filtration supply of the City of St. Louis, would the fact that sewage from Chicago entering the Chicago river and the Illinois river, thereafter commingled with the waters of the Missouri and Mississippi rivers create any additional cost in the expense of the plant or in the operation of such a plant over conditions that would exist if the sewage of Chicago was eliminated?

A. My opinion is that the addition of Chicago sewage via the drainage canal to the system of the Illinois river would not add any additional expenses to the purification of the Missis-

sippi water by filtration at the chain of rocks. The installation
and operation of the plant would not be greater in point
11340 of expenses by the addition of the Chicago sewage as it
now is added to the system of the Illinois river.

Q. Have you any acquaintanceship with any rivers more polluted than the waters in the Mississippi at the chain of rocks that have been successfully treated by a process of filtration?

A. Yes, sir.

Q. What are they?

A. As an illustration I shall mention the Elbe river at Hamburg and the Hudson river below Troy, which latter supplies both Rensselaer and Albany.

Q. Any others?

A. There are. I do not recall the analytical data just now. You would have to let me look over a number of them to answer your question.

CROSS-EXAMINATION, by Mr. Jeffries.

Q. Professor, in the examination of water supply, what do
you say as to the sanitary condition of water, the examination
ranging daily for a period of one month, and these examinations
being made at the rate of 24 per day, and in the examina-
11341 tion the germs of typhoid fever should be disclosed upon
the plates three times, what would you say as to the
sanitary condition of that water?

A. I should say that the water contained typhoid fever unquestionably.

Q. Is it not a fact that the germ of typhoid fever is a very difficult thing to find in a water supply?

A. Yes, sir.

Q. Is it not a very difficult matter to discover it in a composition known to contain it?

A. It often has been sought for in a water where it was known to be present and has not been found.

Q. In the hypothetical question propounded to you by Mr. Todd in reference to the bacillus prodigiosus, and assuming that the germs of typhoid fever were contained in the waters of the Mississippi river at St. Louis, when these bacilli prodigiosus were found during that series of experiments, 2 typhoid fever germs had been discovered, and that these discoveries represented a fair distribution of the germs in the waters of that river, what would you say as to the sanitary condition of that water?

11342 A. I should say that if I understand your question right, assuming that your question is for me to draw a parallel between the presence of the prodigiosus and the presence of the typhoid bacillus—

Q. Assuming that the typhoid was there. It assumes that.

A. It assumes that?

Q. Yes, sir?

A. I should say that there was typhoid found there to the extent that it was found. With reference to the death of the typhoid bacillus, its rate of death, I should have to have some notion as to the numbers that have died out between the points at which it was admitted and the point at which it was found.

Q. But assuming, Professor, the actual presence of the typhoid fever germs in the water of the Mississippi river at St. Louis, and that the number of times that it was found in proportion to the number of examinations that were made represented the bacterial condition of the water of the Mississippi river with reference to this particular germ, at the chain of rocks, what would you say as to the sanitary condition of that water?

A. You do not wish me to include in my answer the 11343 number of samples from the laboratory tap?

Q. No, sir, only such samples taken at the chain of rocks from the intake.

A. Which was 720. My opinion would be that a water sampled at the chain of rocks 720 times and the typhoid bacillus was found twice, that it would be a water certainly containing typhoid fever, as the facts show, but not to such an extent as to be prejudicial to a city supply, provided the supply were used after filtration.

Q. If the examination discloses two typhoid fever germs in 700 analyses of a water, would that water be condemned by a sanitarian as an infected water?

A. It would not be condemned by me as a raw water for a city supply. Might I say when I make use of the expression "raw water" that before the water is actually given to the people it must be improved by artificial means and filtered.

Q. But it would be condemned for use in its raw condition?

A. I would condemn that river in its raw condition.

Q. Are sanitarians a unit upon the longevity of the typhoid bacilli?

A. I should judge that they were not.

11344 Q. Upon what does the longevity of the typhoid fever germ depend?

A. It depends upon the conditions under which the germ finds itself after leaving the human body.

Q. And as contained in a running stream are not the conditions which control and regulate, to a large extent, the longevity of the typhoid germ continuously changing?

A. In a general way, no. Very strictly speaking that is true, and it is because of the material which flows into a stream, which, being the drain of a country, takes all kinds of material added thereto, from pure spring water flowing in at its fountain head to polluted material which may flow from its banks.

Q. Is not the life of the typhoid bacillus governed to some extent by local conditions, surroundings and by the effects of dilution, less and greater concentration, and by temperature and floods?

A. Inasmuch as all the conditions which you have named do occur in rivers, there would be variation of course in the longevity of typhoid germs, subject to variation in temperature and in the other items that you have enumerated in your question.

Q. Assuming, Professor, the longevity of the typhoid 11345 germ to be from 1 to 30 days, with gradual diminishing numbers, and that such germs be deposited into running streams would not changes taking place from one end of the year to the other in that stream affect in a general way the longevity of the germ?

A. Under that assumption that the average longevity of a typhoid germ is somewhere between 1 and 30 days, there is no question but that there would be a variation in the longevity, although a small one, as the conditions under which it finds itself might vary.

Q. Now, name some of the conditions which would bring about such variable results?

A. If, for instance, a germ should find itself suddenly immersed in water containing large numbers of saprophytic organisms which would produce conditions adverse to the life of that germ of course the period of longevity would be diminished. On the other hand, if the germ should find itself in a water of greater purity, particularly if the water approached the limit of sterility, the longevity of that germ would be increased.

Q. Would the change in temperature of the water have
11346 any effect upon the germ?

A. Yes, sir. As the water fell in tempertaure the germ would be adversely influenced, especially near the point of freezing, and when frozen in the ice itself the tendency would be to gradually die from such exposure. Alternately freezing and thawing would be particularly adverse to its life.

Q. Taking into consideration your knowledge of the waters of the Illinois river, and from your information upon the variableness of the life of the typhoid germ in a running stream can you, as a sanitarian, designate any particular point in the Illinois river wherein the pathogenic bacteria coming from the sewers of Chicago will not reach during any portion or part of the year or on any day of the year?

A. My opinion is that in consideration of the facts regarding the Chicago sewage being dumped into the Illinois river, as at present, and the facts concerning the conditions of the Illinois river, that the germs of typhoid fever coming from Chicago sewers would be destroyed en masse by the time the mouth of the Illinois was reached, although some resistant organisms
might go beyond that point, such organisms, however,
11347 representing a small number and in my opinion low
vitality.

Q. Is it not a fact, Professor, that the vitality of the typhoid organisms as well as pathogenic bacteria depend largely upon their inherent faculties and qualities for their longevity, and that the longevity of these germs is variable on account of a difference in the inherent qualities or faculties of the respective germs?

A. My opinion is that the longevity of the typhoid germ depends in the first place upon its parentage, but in the second place it depends upon the conditions under which the germ is grown, and the conditions with which it finds itself surrounded.

In the same way, an individual may come from a healthy parentage and live in a healthful form, but, because of conditions surrounding that individual, his vitality may be greatly lowered. Just so with the typhoid germ, should it struggle, for instance, over periods of time it will lose, in my opinion, the vigor of its life, and be incapable of producing its normal amount of poison. My reason for this belief is as I have already shown in my direct testimony that there seems to be a great loss in poison-
11348 ing power of the germ when the period of time is lengthened between the point of infection of a water and the point of time when such water is drunk.

Q. Is it not a fact that the typhoid fever germs from some typhoid patients are possessed of greater vitality than the germs from other typhoid fever patients?

A. That is true with reference to pathogenic germs in general, for the same reason that a crop of turnips grown upon a good soil would be better than one grown upon a poor.

Q. These variations about which we have spoken and commented upon, render it impracticable and impossible for scientists to definitely determine the longevity of the typhoid fever germ within certain limits, under variable circumstances and conditions in nature?

A. My opinion is that it is impossible to tell what shall be the longevity of specially resistant cells. Experimental data have shown that for the general mass the longevity is fairly well fixed, so that a good deal of knowledge has been obtained with reference to the average germ, although we are still in ignorance as to the longevity of specially resistant individuals.

Q. May it not be true that these specially resistant
11349 typhoid fever cells and the specially resistant cells of all pathogenic bacteria are in reality the ones which produce disease?

A. My opinion is that these specially resistant cells at their point of departure from the human body are fully as capable or even more fully capable of producing disease than the greater numbers of their less resistant brethren, with whom they start upon their journey, after leaving the body. Whether they arrive, after the interval that may be chosen for the period of investigation, in a condition to produce disease, may be open to question, because the mere fact of their being resistant enough to arrive living, does not mean that they will have enough toxin producing powers left to form that serious poison which may cause disease.

Q. That, however, is a matter of speculation?

A. That is a matter of speculation.

Q. Professor, is it not a fact that in the examination of water supplies, sanitarians are more interested in making a determination of the actual or probable presence of pathogenic bacteria rather than the quantity or numbers of such bacteria?

A. Whatever their interest may be their practice is not to look for them at all, for the simple reason that it does
11350 not pay. The negative results are so frequent that, taking typhoid fever as an instance, water examiners have given up search for that germ as a routine portion of their water examinations and have fallen back upon the determination of the bacillus coli communis as an indication of bowel discharges without inquiry as to whether those bowel discharges came from bowels that were diseased or bowels that were in a normal degree of health.

Q. But regardless of how the determinations may be made, the possible presence of the pathogenic bacteria is of more concern to the sanitarian in passing judgment upon the sanitary condition of water than the number of pathogenic bacteria that may be present, is it not?

A. Were it possible to tell actually the number of pathogenic germs in a given water at a specified point, why of course it would be desirable to obtain a knowledge of that number, but it is not possible with any degree of accuracy to uniformly make a determination of the number of typhoid germs in a water at any particular point in routine work, and for that reason they fall back upon something that will be indicative of what
11351 has taken place in the water as the determination of the presence or absence and the approximate number of the bacillus coli communis.

Q. Professor, do you know what was the condition of the Illinois river prior to the opening of the drainage canal? In other words, had you ever observed it personally before that time?

A. Never. I made it but one visit.

Q. The only personal observation that you ever made of that river was in 1903?

A. September, 1903.

Q. Professor, assume that a gallon of infected typhoid dejecta be deposited in the waters of Lake Michigan at a point free from sewage contamination, what would be the character of the bacteria that would first disappear from that water which was formerly contained in the composition just mentioned?

A. How is it to be deposited in the water?

A. Deposited in the lake at a point where it is free from any sewage contamination. In other words, take the pure lake water, as near as you can?

A. Under those circumstances the typhoid bacteria would disappear first.

Q. What is your reason for giving that?

11352 A. Because they would be surrounded by myriads of bacteria, ordinary saprophytic bacteria and those bacteria would set up conditions which would be prejudicial to the life of the typhoid germ. Even though it be deposited in the body of the lake, although the period of longevity I should expect to be increased. Nevertheless the typhoid bacillus would disappear before the lake bacteria would disappear.

Q. Would it disappear before the ordinary sewage saprophytes would disappear?

A. Yes, sir, it would.

Q. Do you know anything about the longevity of the ordinary saprophyte in sewage?

A. I could not tell you.

Q. Does not the life of the ordinary saprophyte depend upon its environment also?

A. . It does.

Q. Is it not a fact that as soon as the object or the purpose of the saprophyte has been served and his usefulness exhasuted that he expires?

A. That is his end.

11353 Q. Now, then, whenever he becomes subject to an environment that is of no service in the purification of that water he has run his course?

A. Yes, sir, unless there be food for him he dies.

Q. Do you know how soon he dies after food is removed from him?

A. I could not tell you; probably shortly.

Q. Is it not a fact that the life of the ordinary saprophyte in a composition undergoing purification is indeed very short, and that their decomposition is brought about by the increased numbers of saprophytes that each respective bacterium creates until their course has become exhausted?

A. As a general statement that is true.

Q. So that in that respect the life of the saprophyte in water differs from the life of the typhoid and other pathogenic bacteria in water?

A. In that respect, yes, because the typhoid is merely a foreigner there who has no purpose to fulfill and he is not doing any work.

Q. What effect has dilution upon bacterial life in water?

A. If you have a certain number of bacteria present, in water, and then should dilute the same you would diminish the number of bacteria there because they would be
11354
further separated. I mean, when I say "diminish the number" that you would diminsh the number per gallon.

Q. What effect would that dilution have upon bacterial longevity?

A. I will have to be a little specific, perhaps. Take, for instance, the typhoid fever germ, the dilution would tend to make his longevity greater because it would diminsh the concentration of his adversaries.

Q. Assume, Professor, that prior to the opening of the drainage canal, during a great portion of the year, the Illinois river was a stagnant or quiescent body of water, that if you would cast a chip or a chunk or a piece of board into the water, it would depend altogether upon the wind as to the direction that that board would travel; that there was a green scummy formation upon the water of that river; that since the opening of the drainage canal the volume and velocity had both been increased, and at no time during the year is the river without a current, and at no time is it subjected to the green scummy formation. Is it not a fact that those conditions which existed prior to the opening of the canal were more conducive to the destruc-

tion of pathogenic bacteria than conditions assumed in
11355 the question existing subsequent to the opening of the canal?

A. The conditions as stated in the question, of practically no current and a green scum before the opening of the canal and a decided current and no scum after the opening of the canal, those conditions being as stated, the two waters before and after the opening of the canal being equally infected, by supposition, the conditions obtaining before the opening of the canal would be more favorable to the destruction of typhoid bacilli than those obtaining after.

Q. Assuming, Professor, that there were typhoid fever germs in the waters of the Illinois prior to the opening of the drainage canal, and that the same population resides upon the watershed of the Illinois river, since the opening of the canal as prior thereto, that practically the same number of typhoid cases which would produce typhoid fever germs and from thence be discharged into the Illinois river subsequent to the opening of the canal that existed prior thereto, is it not a fact that the conditions assumed in the last preceding question are such that are conducive to the longer life of the typhoid bacilli thus discharged into that river than they were prior to the opening of the drainage canal?

11356 MR. TODD: I object to the question as assuming that the conditions of stagnation such as assumed in the previous hypothetical question and made a part of this were conditions that obtained at all times throughout the year upon the Illinois river prior to the opening of the drainage canal for the reason that the evidence in this case discloses a contrary condition to exist and the condition assumed exists only for a short period of time.

A. My opinion is that those conditions would, from a practical standpoint, increase the longevity of the typhoid germ, but I do not believe, and it is my opinion in fact, that such increase would be not material from a practical standpoint.

Q. Professor, assume that the dams in the Illinois river were removed, and that the river, so far as the overflowed ground is concerned, was leveed practically from one end to the other, what effect would the removal of the dams and the leveeing of the land have upon the question of sedimentation as effecting the removal of pathogenic bacteria from the waters of the Illinois river?

MR. TODD: I object to the question for the reason it is not proper cross-examination and for the reason that 11357 the assumption that the river is to be leveed, or that it ever will be leveed is based upon no evidence that has been produced in the record so far as has been or will be produced by complainants and for the additional reason it is based upon an impossible, impracticable assumption that never has and never will exist upon the Illinois river, to-wit: that the river will be leveed from one end to the other, and therefore the question is not competent unless counsel is prepared to state that he will offer evidence that such a condition at some future time will be carried out.

MR. JEFFRIES: In answer to counsel's statement I suggest that it is not necessary to prove what the intention of the people owning the overflowed land on the Illinois river is. It is a known fact of which the court will take judicial knowledge that levees are projected for the protection and preservation of overflowed lands along the river streams, and that in view of this public necessity appeals have been made to national and state legislative authority, coming from various parts of the United States, which appeals have not been disregarded and as population grows and increases in the Illinois river valley 11358 the presumption is that the work of leveeing low lands will be continued as they have been until practically every foot of redeemable soil is preserved.

MR. TODD: I move to exclude the statement made by counsel in his reply to my objection for the reason that there is no evidence in this record that justifies the statement which he has made and this case is being tried upon the records and not upon presumptions, either of law or of fact.

Q. Question repeated.

A. The removal of the dams and the leveeing of the river from one end to the other would interfere with sedimentation and its resulting purification by sedimenting bacteria of the pathogenic type.

Q. What effect would it have upon the velocity of the stream?

A. It would increase the velocity of the stream.

MR. TODD: Objected to for the same reasons given.

Q. Professor, in the tables introduced in evidence by Professor Jordan covering the bacterial count examination of the waters in the Illinois river at Grafton, from October 1, 1901, to December 24, 1901, and on the Mississippi at Grafton from October 21, to December 24, 1901, the maximum bacterial 11359 count in the Illinois river at Grafton was 123,000, the minimum 210, the average bacterial count for the period in the Illinois river at Grafton 6900; in the Mississippi river during the same period the maximum bacterial count was 3700; the minimum 360, the average 1300. Taking into consideration your knowledge of the population upon the watersheds of the respective rivers, which would you consider from this bacterial exhibit the better for sanitary purposes?

A. So far as the total count is concerned it shows the Illinois at Grafton to be inferior to the Mississippi at Grafton. Where those bacteria came from is of course important. Is it true that they represent ordinary soil bacteria washed into the Illinois river because of special conditions in the way of local rainfall, or don't they? I don't know. Right on the face of it, judging merely from the count as it stands, the Illinois is inferior to the Mississippi at those points.

Q. Professor, upon examination of the tables 91 and 141, introduced in evidence by Professor Jordan, for the period November 1 to December 24, 1899, as compared with the period from January 4 to March 7, 1900, the average temperature of the water in 1899 being 7 degrees centigrade and in 1900 8.3 degrees centigrade during that period of 1899 the aver- 11360 age bacterial count was 3190 during the period covered in 1900 the average bacterial count was 32,600. Assuming that these examinations were made from water taken from the same river at the same point, although at the two respective periods, what would you say as to the sanitary condition of that water judged from these bacterial counts, so far as the year 1899 being superior or inferior to that of 1900?

A. I should not wish to compare those at all because my experience is that waters in the late fall and early winter are not comparable in the matter of counts with waters in the early spring. You would have a tremendous amount of washing of surface bacteria into the stream in a period of thaw, so I would not wish to compare those waters at all.

Q. Professor, is it not a fact from the tables of analysis as shown in the book known as Streams Examinations, all of which have been introduced in evidence in this case, that since the opening of the drainage canal there has been a reduction of the constituent known as chlorine to a larger and greater extent comparatively speaking than other chemical constituents of the water in the Illinois river at all points where examinations were made, thus showing the diluting effects of the water of the Lake Michigan passing through the drainage canal
11361 upon the chlorine and the effect of the preservation of other chemical constituents that might be contained in that water and is it not a fact that these data also show a preservation of the bacterial counts on the numbers of bacteria that are contained in the water?

A. It is a fact that chlorine has been reduced all along the line by the opening of the canal, but it is also a fact that albuminoid and free ammonia have been reduced as well. Nitrates towards the end of the canal have been increased.

I have made no estimate which would enable me to say whether or not the chlorine has been reduced in the same proportion that the other items have been reduced, such as ammonia, free and albuminoid. All that I can tell you is that they have been reduced, but their relative rates of reduction I can not tell you.

Q. Professor, I show you a copy of table E, which is a copy of a table introduced in evidence by Professor Edwin O. Jordan, entitled "Streams Examination, Sanitary District of Chicago. Sanitary Water Analysis. Parts per million. Comparative averages 1899 and 1900."
11362 Now, based upon your answer to the second preceding question, I will ask you if the chemical and bacterial data disclosed by this table comparatively speaking, for the period from April to December, 1899, and from January to April, 1900, on account of being at different times of the year are comparable with each other?

A. I think that they are not, and for the reason I think so let me take as an illustration, the Illinois river at Grafton. The Illinois river at Grafton in 1899, the results from May to

December—the Illinois river at Grafton in 1900, the results are from January to June, namely the other half of the year. I do not feel that it is wise to compare waters of the same stream at such widely different periods of the year because in one instance you get the benefit of the spring changes and in the other case you get whatever influences may come from the changes of the summer and autumn.

Q. And what is true with reference to table E is also true with all other tables of a like character?

A. When the waters compared have been sampled and analyzed during periods of the year which are not similar.

Adjourned until 2:00 p. m., of same day.

11363 2:00 p. m., Monday, March 7, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. W. P. MASON

resumed the stand for further cross-examination, by Mr. Jeffries, and testified as follows:

Q. Professor, in undertaking to analyze the relationship existing between the typhoid fever mortality in the City of St. Louis with that of Chicago is it not a fact that the physical conditions of the Illinois river, together with the temperature of the water, have some effect upon this relationship—that the variable physical conditions of the Illinois river?

A. No. When I undertook to analyze the typhoid conditions in those two cities I stated them simply as facts and those facts stand out without any question whatever as to what happened to be between the towns. Were there no Illinois river
in existence the facts would stand that the deaths in Chi-
11364 cago were such and such, and the deaths in St. Louis
were such and such, and the charts show the relative tracings.

Q. And those charts are made without regard to the changes in the bacterial and chemical condition of the Illinois river at various times?

A. Surely. Those charts are simply from the reported figures from official sources. In other words, those charts could be made by a man who did not know whether there was any water between Chicago and St. Louis.

Q. In other words, those charts are made as though one city was situated upon the Pacific Coast and the other upon the Atlantic?

A. Certainly. Anybody could have made those. What is between the cities would have no influence upon the way that the man in question drew those charts from the figures given. The charts would appear as they are.

Q. But what is between those cities might have some effect upon actual typhoid conditions?

A. The deaths in St. Louis might be attributable to something existing between those cities. Such does not appear as a fact upon the chart.

Q. In other words, all the factors which materially enter into the longevity of a typhoid germ in passing down stream between two given points is not displayed in those charts?

A. Nothing is displayed in those charts but the number of deaths in those two cities.

11365 Q. Now, in those charts you have removed St. Louis one month in advance of Chicago, have you not?

A. I have.

Q. For what purpose was that done, Professor?

A. Because the deaths of Chicago, due to typhoid fever in one month, if they be related to deaths from typhoid fever in St. Louis, such relation will show in the death rate of St. Louis for the following month. Therefore, I moved the death rate of St. Louis one point to the left merely for the sake of easy comparison. I might have left them where they naturally would fall. Under those circumstances, however, a man in examining the charts would have some little trouble in following the oblique lines, and direct comparison would not be so easy.

Q. Suppose that the period of incubation be two weeks and the duration of illness three weeks, on an average, without counting the time of stream flow, would those charts correctly represent the conditions which they are intended to display?

A. If I were obliged to account for an interval of five weeks it would be necessary to shove those St. Louis records

11366 slightly to the left beyond the point where they were pushed.

Q. And assuming that the stream flow time of the Illinois river was from 10 to 20 days, and on an average of 14 or 15 days, it would be necessary to shove St. Louis still further to the left?

A. Yes, sir; so that it would be shoved perhaps a month and a half all together instead of one month, a difference of perhaps two weeks.

Q. Professor, referring to the chart which you introduced in evidence showing the comparative results of the colon test as made by Professor Jordan for 1901, I call your attention to the Illinois river at Grafton, wherein it was disclosed that 7 per cent. of the determinations made produced positive results of colon when .001 cc. of water was used, and basing that determination, to be accurate mathematically speaking, is it not a fact that if 1 cc. had been used in those determinations that it would have been found in more than 85 per cent. of the examinations?

A. No, sir. I do not think that it is an easy matter to compare .001 determination with 1 cc. determination, because the opportunity for error is quite considerable in so
11367 small a volume of water as that. I attach more value to where the larger quantity of water is used.

Q. Does that chart represent the colon condition of the waters in the respective rivers to a mathematical certainty?

A. Assuming that by mathematical certainty you mean, is it thinkable that in some instances the coli were present, sought for and not found, I should say that it does not represent the results to a mathematical certainty. Such determinations can never be upon a mathematical certainty basis.

Q. Is it not a fact that on that chart, taking the 1 cc. determination, that the water in the Illinois river at Grafton shows a greater pollution than the water in the Mississippi river at St. Louis, the Missouri river at Bellefontaine and the Mississippi river at Grafton?

A. That is true.

Q. Is it not a fact, Professor, that some of these percentages are the result of a less number of determinations than others?

A. That is true.

Q. And that such an extent differs the results does it not, the result of the percentages?

11368 A. Of course the larger the number of determinations
that we get the more accurately can our percentage be stated.

Q. Professor, assume that the average flow of the Illinois River for 1900 at Averyville, or at a point above Peoria known as the bridge, was 2874 cubic feet per second or 248,313,600 cubic feet per day, which equals to 10,249,408,000,000 cc. per day, and in this number of cc. 7,375,573,760,000 contain the bacilli coli communis, representing 72 per cent., as shown upon the chart prepared by you from Professor Jordan's determinations, and that the flow from Bear Trap Dam to Averyville is from 4 days and 8 hours to 6 days and 3 hours, and that the sewage of 1,600,000 people in the sanitary district of Chicago was discharged into the Chicago River and the drainage canal, state whether or not in your opinion any of the bacilli coli communis so existing in the waters of the Illinois River at Peoria originated from the sewers of the city of Chicago; assuming further that the sewage discharges from the city of Joliet, Marseilles, Ottawa, Morris, and Peru are discharging directly into the Desplaines and the Illinois Rivers, and taking into consideration also that the Desplaines River
11369 enters this stream at the city of Joliet?

Mr. Todd: I object to the question for the reason that it is not assumed that the Fox River and the Kankakee River and the Vermillion Rivers upon which are situated large towns also empty into the Illinois River between Lockport and Peoria, and no assumption is made as to the rural water sheds of these rivers draining the rural districts mentioned.

A. In my opinion some of those do come from the Chicago drainage canal. How many I do not know.

Q. In your publications you have used both the percentage of mortality system and the numbers per 100,000 in determining the typhoid and other death rates in cities, have you not?

A. When I have quoted from a man who used percentage methods I have given it as he stated it. I have not used that method myself.

Q. Now is it not a fact that if population runs regularly and no epidemic of any character be prevalent that there is very little difference in the two systems so far as applied to a particular city?

11370 A. Assuming nothing unusual in the death rate, why there would be no particular difference between the two methods, but it would be possible to have very misleading results. For that reason I do not use it. I am speaking now of the mortality percentage.

Q. Assuming, Professor, that the population in the city of St. Louis increased from 1890 to 1900 at a rate less than 3 per cent. per annum, would it not be from that standpoint as inaccurate to use the Farr formula as to use the actual population?

A. I am not familiar enough with the use of that formula to answer your question.

Q. Assume, Professor, that the total deaths from all causes in the city of St. Louis from 1890 to 1903, inclusive, are as follows:

1890	8409
1891	9530
1892	10225
1893	10303
1894	8710
1895	9425
1896	9897

11371

1897	9554
1898	8908
1899	10023
1900	9847
1901	10601
1902	10348
1903	11138.

That the population of the city of St. Louis for the year 1890, as shown by the census report was 460,000 and that the population for the year 1900, as shown by the census report is 575,200, and assuming that the difference between census report of 1900 and 1890 be divided equally among the various years intervening between those periods which resulted in an

increase in the yearly population between said census taking of 11,520 per year, and that since the census of 1900 that 11,520 be added to the respective years, to wit: 1901, 1902 and 1903, would that showing in your opinion produce any great difference between the two formulas or systems used, to-wit: the percentage of deaths to the total mortality or the number of deaths from typhoid fever per 100,000 population, and
11372 assuming that from the year 1890 to the year 1902, inclusive, are as follows:

1890	227
1891	166
1892	488
1893	215
1894	178
1895	106
1896	106
1897	125
1898	95
1899	130
1900	168
1901	198
1902	222

A. Basing my reply on the numerical data submitted in the question, it is my opinion that there is no material difference between the two methods of stating the result.

Q. Professor, is it not a fact that of the longevity of the
11373 typhoid fever germ, as well as other pathogenic bacteria, in all the various conditions in nature in which it may be found or may exist, taking into consideration climatic influences and all of the elements which affect the vitality of those organisms, scientists have been unable thus far to formulate any rule or formula by which the longevity of the germs may be measured within certain accurately defined limits?

Scientists have thus far been able to determine the longevity of pathogenic germs only within roughly accurate limits.

WILLIAM P. MASON.

ADJOURNED UNTIL 10:00 A. M., TUESDAY, MARCH 8, 1904.

11374 10:00 A. M., Tuesday, March 8, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

No witnesses being present an adjournment was taken to 10:00 A. M., Wednesday, March 9, 1904.

11375 10:00 A. M., Wednesday, March 9, 1904. Continuation pursuant to adjournment. Present the commissioner and same counsel representing the respective parties.

No witnesses being present an adjournment was taken to 10:00 A. M., Thursday, March 10, 1904.

11376 10:00 A. M., Thursday, March 10, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

RUDOLPH HERING,

a witness called on behalf of the defendants, after being duly sworn by the Commissioner, was examined in chief by Mr. Todd and testified as follows:

Q. What is your name?

A. Rudolph Hering.

Q. What is your business?

A. Hydraulic and Sanitary Engineer.

Q. Where is your place of business?

A. New York City.

Q. Under what name are you doing business in New York City?

A. As Hydraulic and Sanitary Engineer.

Q. I mean under what business name?

11377 A. The firm is Rudolph Hering and George W. Fuller.

Q. Composed of yourself and Mr. George W. Fuller who testified in this case?

A. Yes sir.

Q. Are you a graduate of any educational institution? If so, please state which one?

A. I took the course in civil engineering at Dresden, Germany.

Q. When was that—what year?

A. In 1867.

Q. After taking that course what did you do next?

A. I came home and started my engineering work in Brooklyn on Prospect Park and then went to Philadelphia on Fairmount Park and in 1872 was employed on the Geological Survey of the United States Government, making the first survey of the Yellow Stone National Park and in 1873 went back to Philadelphia where I was first assistant Engineer in the Department in charge of bridges and sewers until 1880. In 1880
I went to Europe, commissioned by the National Board of
11378 Health, at Washington, to make an examination of and
to report on European sewerage systems. I spent almost a year on that work, largely on my own account, studying also questions of water supply and other municipal problems.

Q. What cities in Europe did you visit on this occasion, studying the disposal of sewage?

A. All of the large cities of England, France, Germany and Austria.

Q. Did you make a report to the National Board of Health as a result of that visit?

A. I did.

Q. Was that report published?

A. It was in the Annual Report of the Board for the year 1881.

Q. How extensive was that report?

A. It went over the subject of sewerage very fully and answered the question which was one uppermost in the public mind at that time, as to the relative advantages of the separate system of sewerage and combined system of sewerage.

It gave a large amount of statistics from all of those cities, and also maps showing the methods of sewerage and drain-
11379 age practiced there.

Q. After you had completed that work what did you do?

A. I then acted as engineer for a number of cities in an advising capacity or as designer or constructor of works.

Q. What cities?

A. From 1883 to the spring of 1886, I was engaged by the city of Philadelphia to make investigations for a new water supply for that city, and incidentally also for a number of other smaller cities.

In 1882 I was engaged by the city of Cleveland to make a plan of sewerage for the interception of the sewage and cleansing the Cuyahoga River.

After the Philadelphia work was completed, the Mayor of Chicago, Carter H. Harrison, employed me to come here as Chief Engineer of the drainage and water supply Commission and I stayed here about two years.

Then I was appointed Consulting Engineer for the Sewerage works of New York City, by the Commissioner of Public Works and stayed there two years, and since that time I have been engaged by a very large number of cities in the United States and Canada, and also outside, in making plans
11380 and designs for sewerage and water supply works.

Q. What engineering works in this country have you been connected with that dealt with water supply and sewerage disposal of cities in the last ten years?

A. In Philadelphia I was on the Commission to report on a new water supply and recommended filtration of the water, which is now being carried out.

Q. Who made the plans and specifications for the filtration of the waters at Philadelphia—under whose direction?

A. Our commission made the general plans and the detail plans and specifications were carried out by Mr. John W. Hill, who is now the chief engineer of the Filtration Bureau.

I then made a report for the city of Baltimore, also on a commission for the sewerage of that city.

I also made a report, at the request of President Harrison, as Chairman of a Commission to devise a system of sewerage and drainage for the city of Washington, which is being carried out.

I have also been connected with the city of New Orleans for ten years on their works, for a sewerage, drainage and water supply.

11381 Q. Is that New Orleans work being carried out?

A. The works are under construction now.

Q. Are you acting now in any capacity?

A. Yes sir, as consulting engineer.

I was also consulting engineer for the city of San Francisco on their sewerage system, the plans for which were adopted.

I have also been consulted in other cities making a report quite recently on the water supply of Pittsburg, Pennsylvania, together with Col. A. M. Miller, U. S. A., and Mr. John W. Hill, Philadelphia.

I have also made reports on sewerage and water supply works for four or five cities in Canada, St. John, Toronto, Winnipeg and Victoria, and also for Honolulu, Hawaiian Islands, and for Santos, Brazil.

Q. Have you made a specialty of sanitary engineering?

A. I have.

Q. What does the term hydraulic and sanitary engineer embrace in its scope of work?

A. The branch of hydraulic engineering which I have 11382 paid special attention to is the water supply of cities and regulation of small water courses. The branch of sanitary engineering which I have practiced pertains to the collection, removal and disposal of sewage and also garbage of cities.

Q. In passing upon the quality of a water supply for a city, what elements do you take into consideration in arriving at a conclusion, as to whether the water supply is safe or unsafe, proper or improper for domestic and drinking purposes?

A. I take into consideration the quality of the water as judged from the character of the water shed from which the water is derived, from its chemical analysis and bacterial analysis.

Q. Are you a chemist or bacteriologist?

A. I am neither.

Q. How do you utilize chemistry and bacteriologly in your special work?

A. I endeavor to keep posted on the progress made in both sciences so far as they relate to the sanitary condition of the water, and then I take the results obtained by those men in whom I have every confidence and whose ability is unquestioned, and use them in my practice and suggestions for water supply and sewerage works.

11383 Q. When was it that your attention was first called to the sanitary problems of Chicago?

A. In March, 1886, when I received a telegram from the Mayor of Chicago to make him a visit and spend a day here so that he could talk with me.

Q. That was Carter H. Harrison, the First?

A. Yes sir.

Q. Pursuant to that telegram received from Carter H. Harrison, Mayor of Chicago, what did you do, Mr. Hering?

A. I came here and spent a day and returned home.

Q. Then what was the next step?

A. I was engaged as Chief Engineer of the Drainage and Water Supply Commission, and asked to come at my earliest convenience. I was then engaged on the Philadelphia work which was not quite finished, but I see that I entered upon duty on March 28th of that month.

Q. March 28th, what year?

A. 1886.

Q. What did you do after your appointment as Chief Engineer to look into the sanitary problems of Chicago?

11384 A. I made whatever investigations I thought were necessary to answer the resolutions passed by the Mayor and the City Council of the city with reference to obtaining "pure water and scientific drainage."

Q. After your observations were completed did you make any report to the Mayor and the City Council of the city of Chicago as to the conclusions which you arrived at in regard to the sanitary problem of Chicago?

A. I did. In January, 1887, I made a preliminary report, giving the general conclusions which had been reached up to that time.

Q. Will you read that part of the preliminary report prepared by you, which applies to the sanitary problems of Chicago, which you had under consideration?

Mr. Jeffries: I object to it because it is incompetent and irrelevant and immaterial.

A. Witness reads report as follows:

11385 "Chicago, January, 1887.

TO THE HONORABLE MAYOR AND CITY COUNCIL OF THE CITY OF CHICAGO.

Gentlemen: On Jan. 27, 1886, your honorable body passed a resolution authorizing the creation of a drainage and water-supply commission. After being amended Feb. 23, it read as follows:

WHEREAS, Pure water and scientific drainage are necessities of this community, and the people demand a system of water supply and drainage adequate to meet the requirements, not only of the present, but of years to come, nor will any temporary expedient or makeshift satisfy them; and

WHEREAS, A thorough and permanent system of supplying pure water to our citizens and caring for the drainage of the municipality can not be paid for out of current taxation, therefore it is desired that a plan shall be devised and perfected before the next meeting of the legislature, to the end that necessary legislation may be had.

For the purpose of carrying into effect the objects sought, there is recommended the appointment by the mayor of a commission to consist of one expert engineer, whose reputa-
11386 tion is so high that his opinion and report will command
the respect of the community, and with him one or two consulting engineers of like experience in engineering and sanitary matters. The duty of this drainage and water-supply commission, made up as above set forth, should be to consider all plans relating to drainage and water-supply which may be brought to its attention; to make such examinations and investigations and surveys as may be deemed necessary; to collect all information bearing on this problem; to consider all recent developments in the matter of sewage disposal, and their application to our present and future needs; to consider and meet necessity of increasing our water-supply and of protecting the same from contamination; to remedy our present inadequate methods of drainage and sewage disposal; to consider the relations of any system proposed to adjacent districts, and whether there may not be a union between the city and its suburbs to solve the great problem, to determine the great question as to the interest which the state and the United States may have in the

disposal of sewage by way of the Illinois River, and to devise plans to meet any objections thereto, if such system shall be thought best; and in general to consider and report
11387 upon any and all things which relate to the matter of water-supply and drainage of the City of Chicago.

The Commission should report on the whole matter committed to it in the most full and comprehensive manner, with maps, plans, and diagrams complete, and accompany the report with estimates of the first cost and annual requirements for the maintenance of the system proposed.

The report of the commission should be made as early as practicable, and not later than the convening of the next session of the Illinois Legislature in January, 1887.

In consideration of the foregoing, be it

RESOLVED, That the mayor be, and is hereby authorized and directed to employ on behalf of the city one expert engineer of reputation and experience in engineering and sanitary matters, at a salary not to exceed $10,000 per annum, and also to employ such consulting engineers, not exceeding two in number, as may seem necessary, and such assistant engineers as may be required, all to be paid according to services rendered, for the purpose of carrying out the objects set forth
11388 in the preamble hereto. For the fees of said assistant engineers and for all expenses connected with said work there shall be allowed not to exceed the sum of $20,000. All fees, salaries and expenses connected with said work shall not exceed in the aggregate the sum of $30,000, and the same shall be paid from the water fund of the city upon vouchers audited by the mayor and city comptroller.

In accordance with the terms expressed herein His Honor Carter H. Harrison appointed Rudolph Hering as chief engineer, Benezette Williams and S. G. Artingstall as consulting engineers, who, together, should constitute a commission. Mr. Hering entered upon duty March 28, Mr. Williams Sept. 17, and Mr. Artingstall, Dec. 21, 1886.

But the large amount of work alone that was asked for made it impracticable to present a complete report in so short a time. It was expected, however, that results could be reached sufficient to indicate the character of legislation required to carry out any project that might be determined upon, and that

therefore a preliminary report having this end in view could be made at the stated time, leaving to a later date the presentation of a report outlining the detailed features of the
11389 scheme recommended and embracing the minor results of the entire inquiry.

The present communication is to cover the ground indicated for the preliminary report, and besides containing the conclusions reached regarding the main features of the proposed project, it contains also a brief review of the work done during the past year and of what still remains to be done.

The month of April was devoted to a general examination of the subject, of the territory to be investigated, and of the various suggestions that had been made toward effecting a solution of the problem.

The examination disclosed the fact that the city is sometimes greatly suffering from the offensive condition of parts of the Chicago river and its branches, caused by the discharge of sewage into the same, and from the occasional contamination of its water-supply, brought about by the discharge of the polluted contents of the river into the lake. It also disclosed the fact that almost every conceivable way of dealing with these questions had been suggested and in some forms applied during the past thirty years.

The problem therefore demands the attainments of two
11390 ends: the protection of the water-supply and the removal of the river nuisance. As the water must be taken from the lake, it is evident that both its pollution and the objectionable condition of the rivers should be prevented by a better disposition of the sewage. It is therefore the latter question which constitutes the main object of this investigation.

Among the possible methods of getting rid of the Chicago sewage there are but three that have been deemed worthy of an extended consideration, namely, a discharge into Lake Michigan, a disposal upon land, and a discharge into the Desplaines river. The preliminary work has therefore been confined to these three projects, and was classed as topographic, hydrographic, and miscellaneous.

To discharge the sewage from cities into comparatively large bodies of water is not only the usual, but often the best

method for its disposal. Dilution and dispersion thoroughly expose it to the action of the oxygen contained in both the water and the superincumbent air, and it is thereby gradually oxidized. Where the body of water is a large river with a strong current, the best conditions for such purification are found. Where it is a lake in which the circulation is slight and
11391 irregular, the efficiency of the method is less and depends for its success on the character of the currents, and the relative amount of sewage to be discharged into it.

The hydrographic surveys of the lake made during the past season were therefore partly for the purpose of ascertaining, if possible, the laws governing the currents, so that we would know their effect in dispersing the sewage discharged into the lake.

The following results have a bearing on the question of sewage disposal. Where not effected by local conditions the currents practically go with the winds in water of moderate depth, and quickly responded to any change. In deep water also the surface currents run with the wind, but at the bottom and even at mid-depth the direction is usually different. The prevailing current along the shore of Cook county during the past summer has been observed to be toward the north, but it is possible that this result may be different during the winter months. In the open lake wave action seems to be effective in preventing the permanent deposits down to a depth of about sixty feet; inside of the breakwater sewage deposits are found on the bottom.

11392 The general deduction from these results is clear that, as no constant current exists which would carry the sewage away in one direction, it should be discharged into the lake at one end of the future city, while the water-supply should be obtained as far away from it as practicable toward the other end, a conclusion which is being acted upon in the other large lake cities. The proper place from which to bring the water would be opposite Grosse Point, and the sewage discharge should be east of Hyde Park. While it might be practicable to allow the sewage in its crude form to enter the lake under such conditions for many years, the necessity would arise later for clarifying it at least partially previous to its discharge. It could not be allowed to run into the rivers as at present, but the dry weather flow and a considerable amount of storm-water would have to be intercepted and carried to the outfall through many miles of special conduits. And this entire quantity would have to be raised by pumping in order to get sufficient head to empty into the lake, while the diluted sewage during storms, in excess of the capacity of the intercepting sewers, would be allowed to discharge directly into the river.

11393 The water supply would have to be brought from Grosse Point in large conduits to the several pumping stations scattered over the city and its present suburbs. The circulation of the water in the Chicago river and branches would have to be maintained practically as it is at present, because the removal merely of the dry weather flow of sewage would not altogether prevent its pollution.

We shall not at this time enter into a discussion of the principles underlying land purification of sewage or make historical references showing the success or ill-success of the method as practiced elsewhere. We will simply state that with good management under ordinarily favorable conditions, a disposal on land proves satisfactory, so far as the purification of the sewage is concerned, and that with proper conditions in the way of good markets and a favorable soil and climate, sewage farms can be operated on a large scale after the sewage is delivered upon the same, without financial loss.

In speaking of a sewage farm of the magnitude required for the metropolitan area of Chicago, it is not understood as being land devoted primarily to the raising of crops, using the sewage only when and where it would most promote
11394 the growth of vegetation. The primary object would be the purification of the sewage on an area of land as small as could serve the purpose. Technically speaking, the sewage disposal would be by means of intermittent filtration rather than irrigation. To carry out such a scheme for Chicago involves the following:

1. The acquirement of sufficient land suitable for the purpose.

2. A comprehensive system of intercepting and collecting sewers carrying the sewage to the farm.

3. Pumping-works of a capacity to handle all the dry-weather flow of sewage and a certain proportion of storm-water.

4. A thorough underdrainage, leveling, and preparing of beds for the filtration areas.

5. A system of underground conduits and surface carriers for distributing the sewage over the ground, and a system of open ditches for removing the purified water to the nearest water-courses.

6. Buildings, roads, and a complete farming outfit.

7. An organization for properly distributing the sew-
11395 age, for carrying on the farming operations, and for conducting the business of disposing of the crops in the best market.

In making estimates for the size of intercepting sewers, conduits, pumps, and area of land required, we have used as a basis a population of 2,500,000 people, with an average dry-weather sewage discharge of 150 gallons, or 20 cubic feet, per head daily, and made provision for storm-water equivalent to one-fifth of an inch in 24 hours over all portions of the district now drained, or likely to be drained, by a combined system of sewers, allowing surplus-water to escape into the rivers and lakes.

The dry weather flow of sewage would therefore be 50,000,000 cubic feet per day, and the maximum flow of storm-water. 65,000,000 cubic feet per day, making a total maximum discharge of 115,000,000 cubic feet.

It is practicable, however, to exclude the storm-water from the sewers over a large portion of the future city by adopting the separate system of sewerage. The area north of the town of Jefferson and of the middle of Lake View may be treated to advantage in this way, and also a large portion of Hyde
11396 Park, Lake, Calumet, and other adjoining towns.

Assuming that the area which does not allow the storm-water to be entirely excluded is 140 square miles, the average daily amount becomes 10,000,000 cubic feet, which gives, when added to the sewage, 60,000,000 cubic feet, or 24 cubic feet per head of population per day to be provided for on the farm.

As the amount of land required to purify sewage can only be determined by experience, and as this has been very limited in our own country, we are forced to rely mainly upon that of Europe. Without going into details at present, we will simply state that a fair concensus of this experience justifies us in the conclusions that from 10,000 to 15,000 acres of land would be required to dispose of the sewage from the entire metropolitan area.

The only available territory for sewage filtration in the neighborhood of Chicago consists of two sandy ridges in the town of Thornton, extending across the state line into Indiana, and in a sandy ridge crossing the town of Niles. The soil is quite favorable, but the character of the surface is such that the necessary preparation to make it suitable for filtration beds would be comparatively expensive. An enormous cost, is, however, represented by the fact that the sewage would have to be collected by large intercepting sewers, lifted altogether some ninety feet, and carried about twenty miles before reaching the farms. 11397

A third solution of the drainage problem is rendered practicable by the fact that the divide between Lake Michigan and the Mississippi valley lies about ten miles west of Chicago, with so slight an elevation that it is not a difficult matter to carry the sewage from the city westward into the Desplaines river, and thence into the Mississippi river. This method of disposal, as previously explained, is in fact mainly the present one, most of the sewage now being carried across the divide by the Illinois and Michigan canal.

There are two low depressions between the future metropolis and the Desplaines river—the Mud lake valley with the present canal, and the Sag valley west of Lake Calumet. Neither is more than ten feet above the lake, nor do they present any engineering difficulties for canal construction. It is therefore quite feasible to carry all the drainage from the territory ultimately to be occupied by the metropolis, extending from Lake Calumet to Evanston, into the Mississippi valley through these depressions, avoiding thereby all possible lake pollution and permitting the supply of water to be drawn from any number of convenient points in front of the city. 11398

The possibility of this solution was recognized as early as 1856 by Mr. E. S. Chesbrough, and the first step toward its adoption was taken, as already mentioned, by turning the sewage into the Illinois and Michigan Canal. Not until quite recently, however, has it become practicable to consider the construction of a special waterway for sewage removal, because when the pollution was smaller the expense of the undertaking was too great.

The sanitary requirements demand a flow of water large
enough to dilute the sewage sufficiently to make it inoffensive
along the river at all times. Beyond this, any increase in the
size of the channel to provide for the storm-water which naturally
enters it should be kept at a minimum. A glance at the map and
an examination of the ground show the possibility of
11399 diverting the greater part of the storm-water from the
metropolitan district without serious difficulty. Both
branches of the Calumet river can be diverted west of the Indiana state line into Wolf Lake, and thence into Lake Michigan. The Desplaines river can have its flood waters diverted into the North branch near the north line of the town of Jefferson, and the combined waters can be led from Bowmanville directly into the lake.

A second branch of the investigation extends to the elements governing the proper size of the waterway from which a large proportion of the storm-water has been excluded. The area still draining into it will consist largely of paved streets and roofs, allowing of no absorption, and shedding the water rapidly. It requires a careful consideration to determine the maximum quantity of water that may enter the proposed channel, and for which an ample allowance must be made to prevent a back flow of the polluted water to the lake.

The proper degree of sewage dilution in the new channel
demanded a careful investigation. When sewage is
11400 mingled with a sufficiently large quantity of water it not
only becomes inoffensive but readily finds the oxygen
which gradually purifies it. When the surface is covered with ice a greater dilution is necessary for this purpose than at other times when there is a constant replenishment of oxygen from the air. The proposed waterway should of course provide immunity from offense at all times.

The information upon which definitely to decide this question will be given in the final report, as the data have not yet been all collected, owing to the necessity of making actual tests of the oxidation of the canal water under the ice, which is being done for the use of the commission by Dr. J. H. Rauch, Secretary of the State Board of Health. The summer conditions are presented in his late report on the Water-supply and Sewage Disposal of Chicago. The result of these analysis will be compared with those of other streams that are also polluted with sewage in order to show the rate of oxidation with varying degrees of dilution and aeration.

For the purpose of estimating the cost of the water channel we have assumed 3,600 square feet for the cross section and a velocity of the water 3 feet per second, or 2 miles per hour.
11401 This gives a discharge of 600,000 cubic feet of water per minute, or 24,000 cubic feet for each 100,000 persons, which we believe equal to the maximum requirements of a population of 2,500,000 people.

A third branch of the inquiry covers the selection of routes for the proposed canals.

A fourth branch of the inquiry relates to the study of such data as have reference to securing a proper circulation for the waterways within the city.

In the foregoing we have outlined the main features of the only three feasible methods of disposing of the metropolitan sewage, and have given the results of the investigation reached to date. A general conclusion as to the preferable method may be given at present, and also an approximate estimate of cost. But we are not able as yet to give either conclusions or detailed statements of the probable expense regarding all parts of the proposed work, and must defer them until the final report.
11402 In comparing the projects we will first mention their probable cost and then their relative advantages.

The discharge of the sewage into the lake from a population of 2,500,000 in the manner described above, including the extra expense, otherwise not necessary, of taking the water supply at Gross Point, would cost at least $37,000,000, with an annual expense for interest and operation of at least $2,400,000. It would require an immediate investment of about $20,000,000.

To dispose of the entire metropolitan sewage by filtration on land would require an investment of about $58,000,000, with an annual expense of over $3,000,000, for interest, pumping and maintenance, after deducting the profit from the sale of crops. It would be necessary to invest at once about $34,000,000. Land disposal for the sewage from the Calumet region alone, with a future population of 300,000, would require an investment of about $4,000,000, and an annual expense of at least $250,000.

11403 Finally, the cost of the Desplaines project is approximately estimated as follows:

1. A channel from the South fork to Joliet of the capacity heretofore given, will cost between $17,000,000 and $21,000,000.

2. A diversion of the flood waters of the Desplaines, the North Branch, and Salt Creek will cost between $2,500,000 and $2,800,000.

3. Pumping works and locks for the North branch will cost about $150,000.

4. A separate system of sewers to collect the sewage now discharged directly into the lake, and to carry it into the river will cost about $600,000.

5. A channel from Lake Calumet to Sag will cost between $2,500,000 and $3,000,000.

6. A diversion of the flood waters of the Calumet river will cost between $350,000 and $400,000.

The total cost of the Desplaines drainage project would therefore be for the main district between $20,250,000 and $24,550,000; for the Calumet district, between $2,850,000 and $3,400,000. The annual cost, including interest, etc., is
11404 estimated at about $1,300,000 per annum.

It therefore appears that this project is decidedly the least expensive one for the present as well as for the future.

Besides the economical advantage of the Desplaines scheme, its superiority is still further emphasized by advantages of another kind. The proposed canal will, from its necessary dimensions and its regular discharge, produce a magnificent waterway between Chicago and the Mississippi river, suitable for the navigation of boats, having as much as 2,000 tons burden. It will establish an available water-power between Lockport and

Marseilles fully twice as large as that of the Mississippi river at Minneapolis, which will be of great commercial value to the state. The Calumet region will be much enhanced in value by having a direct navigable channel to the Desplaines river, and by a lowering of the flood heights of Calumet lake and river. Within the City the water of the Chicago river and its South branch will get a much better circulation if it flows by gravity than if it has to be pumped, the necessity for which could
11405 remain even if the sewage should be discharged through intercepting sewers either into the lake or upon the land. Under either of the latter conditions an occasional overflow from the sewers into the river during heavy rains would be more objectionable than a constant discharge of sewage into a more rapidly flowing stream. Flood-waters entering the lake by way of the Chicago river would carry into it much filthy matter, either suspended or deposited, notwithstanding the existence of intercepting sewers; but the proposed diversion of such waters before reaching the populated districts will for all time obviate this undesirable occurrence. Lowering the level of the North Branch at Bowmansville by its diversion to the lake will be equivalent to raising the low prairie extending toward Evanston and Niles and greatly benefit parts of these towns.

Respectfully submitted,

(Signed) Rudolph Hering, Chief Engineer.
Benezette Williams,
Samuel G. Artingstall,
Consulting Engineers."

11406 Q. After the report was filed which you have just read, what did you do in connection with this problem?

A. A subsequent report was made in detail covering the proposition to divert water from the north branch near Bowmansville, which is the same as the Lawrence Avenue project. This, I believe, was not printed.

The final report which required the appropriation of some $15,000.00 in addition to the money that had been spent was never made because it was stated that if the preliminary report contained our conclusions and the final report was merely to give the information which lead up to these conclusions, such information could be subsequently published from appropriations made for the proposed sanitary district, and the work was then dropped.

Q. Subsequent to the preliminary report the legislature of the State in 1889 passed a law for the construction of the Sanitary Districts in Illinois did they not?

A. They did.

Q. Since the passage of the sanitary district act in 1889 have you kept in touch with the progress of the drainage
11407 canal and its construction as originally outlined by you in your preliminary report to the elder Carter H. Harrison?

A. In a general way I have. My first visit to the territory after I left Chicago, was during the World's Fair. I have since visited the drainage works on several occasions.

Q. Have you seen the work known as the drainage canal since its completion?

A. I have.

Q. Will you state briefly what were the facts upon which you based your conclusions as found in the preliminary report as already read in evidence, that the drainage canal was the proper solution of the sanitary problem in Chicago?

A. The proposition was a somewhat novel one, and in order to get a safe conclusion regarding the size and other conditions necessary for the proposed drainage canal I was obliged to study into all facts which would point to the best conclusions. Such facts were to be found in Europe and in America. There had been a number of cases of sewage discharged into water courses carefully observed in Europe and in the East as well as at Chicago. This information was carefully collected, weighed and laid the foundation for the recommendation which fixed the size of the proposed channel.

11408 I found that the problem of water pollution and of setting up a standard of purity of the minimum allowable proportion of sewage, or perhaps the necessity of its entire exclusion, required a distinction to be drawn at the outset. If the water is to be used for potable purposes it should evidently be considered in a different light than if a mere inoffensiveness is required.

In view of the absence of such information as we have today, the engineer was confronted with great difficulties for the want of reliable evidence regarding the real danger from pollution. In many cases there was the question whether he should recommend a palatable water, and by far the most economical source of supply, when some hundreds of miles above another community discharged sewage into it. The question was whether he should be governed by the degree of dilution and by the number of days or weeks since the polluted water had a chance to convert the sewage into inorganic and harmless compounds.

The question was different then from what it is now, and
it was necessary to be very careful in the recommendation
11409 of the investment of so large a sum of money as the solution of the Chicago problem involved.

The best information which was available for the purpose, and the most direct, was the observation of Dr. John Rauch, Secretary of the State Board of Health of the State of Illinois, who had been making very careful investigations on the gradual change in the water of the Illinois and Michigan Canal after the water had entered the Illinois River. He fixed a unit of measure which, from a sanitary point of view, he considered sufficient to obviate any substantial injury to the State of Illinois on below. This measure was a flow of water equal to 180 cubic feet per minute for every thousand persons draining in the river at Chicago.

Examinations which I made with reference to the Blackstone River in Massachusetts, which is quite foul at its upper end, and receives much additional sewage on its way, resulted in my conclusion that after a flow of about 140 cubic feet per thousand persons was observed in the river, the character of the water had become entirely inoffensive.

11410 Similar investigations were made from the results obtained in the river Seine, receiving the sewage of Paris, France. The sewage there does not include fecal matter, because this is otherwise removed. It was found on the Seine that where the dilution was 60 cubic feet per thousand people, and after a flow of 14 miles the river was considered unobjectionable to sight or smell.

Also some German Rivers were considered, the Elbe and the Ober, and similar data were secured.

The result from these and still other investigations made me conclude that for the Chicago sewage canal there should be a recommendation that the size is sufficient to carry water at the rate of 240 cubic feet per second for each thousand persons, as stated in the preliminary report.

Q. Have you given the subject of dilution any consideration?

A. I have ever since I was engaged on the Chicago work.

Q. State what facts you have investigated in regard to the question of dilution and what conclusion you have made upon the subject?

A. The practical necessity for utilizing rivers polluted by
sewage from communities in this country has caused the
11411 engineering profession to look into the question of dilu-
tion and my conclusions are as follows:

If the foul water or sewage of a community is liable to enter a stream from whence water is taken for drinking purposes, it is imperative either to purify the water or the sewage. Whereever the stream is not subsequently used for water supply, such a purification may not be required, and it is necessary simply to prevent a nuisance. It is impossible to prevent all disease germs from getting into a water course. We can guard it only against a serious pollution. We can not prevent rain from washing the streets, the fields, the forests and discharging the water into streams, and along with this water must go [illegible] dust of the air and the myriads of bacteria, including disease germs which are sometimes contained in the same. There must go with it also parts of the intestinal discharges of animals, birds and insects, and parts of the manure with which the fields are covered. Therefore much injurious matter is carried into the water courses by the rain water and as it is impossible to
prevent water subsequently to be used for drinking pur-
11412 poses all surface water supplies must in my opinion be
purified.

This is the common opinion now prevalent in some of the countries in Europe. A disposal of the sewage by dilution is still very common and it must remain so for a long time.

Over in Europe we find cities situated on the large rivers discharging their sewage into them with entire impunity. The city of Hamburg discharges its sewage into the Elbe which is a tidal stream at this point. The adjoining city of Altona does the same, and both cities take their water supply from this stream receiving the sewage of over 1,000,000 of people but both cities carefully filter it.

After the preliminary report of the drainage and water supply was published and other papers on the subject of sewage dilution in water courses, the Massachusetts State Board of Health made some investigations with this method as published in their report for 1890. From that information I have compiled a table which I have used since in my professional work, based upon a flow of water in cubic feet per second per 1,000 persons and chemical constituents of sewage in parts per 100,000 which table is as follows:

11413

CALCULATED COMPOSITION OF SEWAGE OF DIFFERENT DEGREES OF DILUTION IN A RUNNING STREAM.

Flowing water.		Ammonia.		Dissolved solids.	Chlorine.	Remarks.
Cubic feet per second per 1000 persons.	Gallons per capita per day.	Free.	Albuminoid.			
		(In parts per 100,000.)				
0.062	40	4.50	.90	65.4	12.6	Dilution is offensive.
0.077	50	3.60	.72	52.3	10.1	
0.093	60	3.00	.60	45.3	8.4	
0.108	70	2.57	.52	37.4	7.2	
0.124	80	2.25	.45	32.7	6.3	
0.140	90	2.00	.40	29.1	5.6	
0.155	100	1.80	.36	26.2	5.0	
0.186	120	1.50	.30	21.8	4.2	
0.232	150	1.20	.24	17.4	3.4	
0.310	200	.90	.18	13.1	2.5	
0.386	250	.72	.14	10.5	2.0	
0.465	300	.60	.12	8.7	1.7	
0.5	323	.5580	.1114	8.10	1.56	
1.0	646	.2790	.0557	4.05	.78	
1.5	969	.1860	.0371	2.70	.52	
2.0	1,292	.1395	.0278	2.02	.39	
2.5	1,615	.1116	.0223	1.62	.31	
3.0	1,938	.0930	.0186	1.35	.26	
4.0	2,584	.0697	.0139	1.01	.19	
5.0	3,230	.0558	.0111	0.81	.16	
6.0	3,876	.0465	.0093	0.67	.13	
7.0	5,522	.0399	.0080	0.58	.11	
8.0	5,168	.0349	.0070	0.51	.10	Dilution is not offensive.
9.0	5.814	.0310	.0062	0.45	.09	
10.0	9,463	.0279	.0056	0.40	.08	
15.0	9,694	.0186	.0037	0.27	.05	
20.0	12.926	.0139	.0028	0.20	.04	
30.0	19,380	.0093	.0019	0.13	.03	
40.0	25,852	.0070	.0014	0.10	.02	
50.0	32,315	.0056	.0011	0.08	.02	
100.0	64,630	.0028	.0006	0.04	.01	

11414 It hardly need be said that in applying the table it is necessary to take into consideration each specific case because no single rule applies to the great differences that we find hydrographically. It is necessary to use careful judgment.

Two lines have been drawn across this table. Above the upper one conditions are indicated where the dilution is practically in all cases offensive. Below the lower one the dilution has never been found to give offense. These two lines are indicated by a dilution of sewage from 2 1-2 cubic feet per second per thousand persons to 7 cubic feet per thousand persons.

It is the duty of the engineer to select between these limits that dilution which conforms to the local conditions of the problem.

Q. In considering this question of dilution what standard did you adopt for the drainage canal?

A. I adopted the standard of 4 cubic feet per second per thousand persons because in the state of knowledge at that time I did not feel justified in recommending a less dilution.
11415 Subsequently, I understand, the number was reduced to 3 1-3 cubic feet per thousand persons, and on that basis the canal was constructed. The dimensions were not altered but it was considered that a larger population than the one which I had figured on would be served by this canal by assuming a less dilution.

Q. From your knowledge of conditions as they obtain in the sanitary district of the drainage canal, as applied to the table that you have already introduced in evidence, what conclusions do you draw as to the dilution?

A. I believe that the dilution which it is intended to give the water at all times is sufficient to prevent offensiveness and in view of what I have said above also improve conditions below.

Q. Have you made any calculations upon the question of dilution of the sanitary canal?

A. I have.

Q. Have you prepared a table of dilution, based on population and flow for 1900, 1901 and 1902 of the drainage canal?

A. I have.

Q. Will you produce and read such table?

A. Such table is as follows:

Years.	Population Discharging Sewage into the Canal.	Maximum.		Minimum.		Mean.	
		Cu. Ft. per Min. Weekly Ave.	Cu. Ft. per Sec. per 1000 Inhab.	Cu. Ft. per Min. Weekly Ave.	Cu. Ft. per Sec. per 1000 Inhab.	Cu. Ft. per Min. Weekly Ave.	Cu. Ft. per Sec. per 1000 Inhab.
1900	1,443,789	351,088	4.05	40,481	0.46	233,976	2.70
1901	1,494,300	615,392	6.86	197,124	2.19	277,153	3.09
1902	1,545,300	450,328	4.85	244.426	2.63	295,527	3.18

11417 Q. Will you please explain the table just read into evidence by you?

A. The table shows the dilution in cubic feet per second per thousand inhabitants which the drainage canal has affected during those three years, and conditions of maximum, minimum and mean flows.

It shows that in 1900 the maximum flow was slightly over 4 cubic feet per second per one thousand inhabitants.

The minimum was less than ½ cubic feet per second per thousand inhabitants, and the mean was 2.7 cubic feet per second per thousand inhabitants. The minimum was caused by the fact, as appears in the table, that the average weekly discharge during that year, which was the first one after the canal was opened, was but 40,481 cubic feet a minute. The canal was not yet in full operation.

In the year 1901 the dilution per thousand inhabitants in cubic feet per second was 6.86, as a maximum, 2.190 a minimum and 3.090 a mean.

These three conditions for the year 1902 are given respectively as in cubic feet per thousand inhabitants per second for a maximum 4.85, for a minimum 2.63 and for a mean 3.18.

11418 Q. How does that dilution come within the table which you have introduced in evidence, prepared by you in 1898, prior to the opening of the drainage canal?

A. The table indicates that the mean discharge during each of the three years was above the line which limits the offensive dilution, therefore, indicating that there should be no offense.

It indicates that during the year 1900 the minimum was much below the standard line above indicated in my table of 1898, heretofore introduced in evidence.

This was due to the fact that the discharge was not yet of the quantity intended.

In 1901 the minimum was 2.19, which is also somewhat below the standard limit, but here also the discharge was not yet the discharge that was intended, and it was due, as I am informed, to the diminution of the velocity in the canal required by the United States Government.

In 1902, when the Chicago river had been somewhat widened, the minimum discharge was 2.63, or above the minimum figure in my table.

It might be added that the conditions of the drainage canal are most favorable to the dilution of sewage because it is 11419 of very uniform section, comparatively all with a regular perimeter, and because the mean hydraulic radius or mean depth is great, all of which would indicate that a less dilution would answer the same purpose that a greater dilution would, in irregular and shallow water courses in which sewage is now often discharged, and where the upper limit of my table is required.

Q. In figuring out the question of dilution as the same applied to the drainage canal dilution being considered from the standpoint of the removal of objectionable qualities and character of the water, what points did you have under consideration in establishing this ratio?

A. I had first and foremost the habitations and cities which lie along the drainage canal and the Desplaines and the Illinois rivers in front of which this water was to pass. As the dilution would become greater by the affluents of the Desplaines and the Illinois rivers on a downward course it was of course assumed that what would be satisfactory with a smaller dilution would be and was generally satisfactory with the greater dilution.

11420 Q. Have you investigated the question of sewage disposals in Europe and in this country since the filing of your preliminary report?

A. I have.

Q. How extensive have been your investigations upon that subject since the recommendations contained in the preliminary report which has already gone in evidence?

A. They have been quite extensive. I must have had surely 50 cases of sewage disposal under consideration myself, and I have examined the principal European works every time I have been there which has been three or four times since then.

Q. Have you kept in touch with the progress of the drainage canal and the work done by that canal for the purification of sewage and the water supply of the city of Chicago since it was opened in 1900?

A. I have.

Q. From what you know of the question of the disposal of sewage and from all the knowledge which you have in regard to the drainage canal, the manner in which it is operated, the purposes served in its operation, and taking into consideration the experience which you have had since you made your preliminary report, what changes would you recommend for the sewage disposal of the city of Chicago today, if the same problem was submitted to you now that was submitted to you in 1886, as a sanitary hydraulic engineer? 11421

Mr. Jeffries: Object to the question as incompetent and immaterial.

A. In considering the several possible ways of disposing of the sewage of Chicago from present knowledge and experience my recommendation today would be that the sewage of Chicago should be disposed of by dilution through a channel substantially like that which has been constructed with a subsequent discharge into the Desplaines and Illinois rivers.

MR. TODD: In the study of this problem have you discovered anything that would change the views expressed by you in the preliminary report at that time?

A. I have not.

Q. Have you a chart showing the comparative pollutions of the Illinois, Mississippi and Missouri rivers?

A. I have.

11422 Q. Will you produce and make such chart a part of your testimony?

A. Yes. The chart, with the caption "Sanitary District of Chicago, Schematic representation of the self-purification of the waters of the Missouri, Mississippi and Illinois rivers between the points indicated, based upon the length of life of the typhoid bacillus, as fixed by experiments made under the direction of Hiram F. Mills," the results of which are given in the paper entitled "Typhoid fever in its relation to sewage supply," is as follows:

11424 Q. Will you state in detail upon what facts this chart was constructed, how constructed and what information it is intended to convey?

A. The chart contains two diagrams. The lower one exhibits the profiles of the Missouri, Mississippi and Illinois rivers above St. Louis.

The upper line indicates the Missouri river as far as Omaha.

The next line the Mississippi river as far as Minneapolis and the third line the Illinois river as far as the city of Chicago.

The three profiles are plated relative to their elevations and to their distances above St. Louis.

It will be seen from these profiles that the Missouri river is the steepest of the three, that it falls from Omaha at an elevation of 960 to St. Louis at an elevation of about 380 above sea level.

The Mississippi river falls from Minneapolis at an elevation of 794 to the elevation above mentioned at St. Louis.

11425 The Illinois River and Sanitary District Canal fall from an elevation of Lake Michigan which is about 578 to Grafton where it enters the Mississippi river. The elevation at Grafton is slightly over 400 feet above sea level.

The distance of Omaha and Minneapolis to St. Louis by water is about 680 miles.

The distance from Lake Michigan to St. Louis by water is about 400 miles.

It will be seen that the Missouri river is the steepest one and the velocity of the water in the river is the greatest. The Mississippi river is the less steep and the velocity would be less great. Therefore, it will take the water longer to flow from Minneapolis to St. Louis than from Omaha to St. Louis, although the distance is nearly the same.

The Illinois river is the flattest of the three rivers and the water has a less rapid velocity.

The upper diagram on the chart exhibits certain deductions made on the basis indicated in the title with reference to the longevity of the typhoid bacillus as found by Mr.

11426 Miram F. Mills. In the above mentioned report it is stated "to prove whether typhoid fever germs would survive in the Merrimack river water, when at the low temperature of the month of November, long enough to pass from the

Lowell sewers to the service pipes in Lawrence, a series of experiments was made by the Board by inoculating water from the service pipe with typhoid fever germs and keeping the water in a bottle surrounded by ice at as near freezing as practicable for a month, and each day taking out 1 cc. and determining the number of typhoid fever germs. The number continually decreased but some survived 24 days:

On the first day there were 6120 germs.

On the fifth day there were 3100 germs.

On the tenth day there were 490 germs.

On the fifteenth day there were 100 germs.

On the twentieth day there were seventeen germs.

On the twenty-fifth day there were no germs.

The ordinates of the curves presented on the diagram represent the relative number of typhoid bacilli still living at towns indicated in terms of population of such towns, it being assumed in the absence of other information at hand that the number of germs is directly proportioned to the population. 11427

From an inspection of the diagram it will appear that Chicago is situated, so far as the average flow of water is concerned, about 18½ days from St. Louis. Kansas City, on the Missouri, on the same basis is situated about 6¾ days and Omaha about 11.6 days from St. Louis.

On the Mississippi river, Minneapolis and St. Paul are situated about 15 days from St. Louis on the same basis. The other cities indicated are at shorter distances.

The conclusions of the chart as indicated by the ordinate at St. Louis is that the relative proportion of typhoid bacilli arriving at St. Louis from the populations situated on the Illinois, the Missouri and the Mississippi rivers, between the limits of Chicago, Omaha and Minneapolis, are about as 13 to 96 to 107, respectively. These figures are merely the proportions. They indicate the relative frequency of the still virulent typhoid bacilli at St. Louis, arriving there from various cities on these three rivers, based on the population of the cities, and also based on the examinations made by Hiram F. Mills as to the longevity of the typhoid bacilli.

Adjourned until 2:00 p. m., same day, March 10, 1904.

11428 2:00 p. m., Thursday, March 10, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

RUDOLPH HERING

resumed the stand for further direct examination, by Mr. Todd, and testified as follows:

Q. Were you acquainted with the Illinois system and Missouri rivers prior to the opening of the drainage canal in 1900?

A. I was in a general way.

Q. What is your opinion as to whether the Mississippi river above Grafton was a safe water for drinking and domestic purposes, in its raw state, prior to 1900?

MR. JEFFRIES: I object to that as immaterial.

A. I consider that the Mississippi river, in its raw condition was not a fit supply for drinking water for any modern community.

Q. Was the Illinois river at Grafton?

A. It was not.

11429 Q. Or the Missouri river at its mouth?

A. It was not.

Q. Is the Missouri river, today, in your opinion, a safe drinking water in its raw state ?

A. It is not.

Q. At its mouth?

A. It is not.

Mr. Jeffries: I object to that as immaterial.

Q. Is the Mississippi river above Grafton a safe drinking water in its raw state?

MR. JEFFRIES: Objected to for the same reason.

A. It is not.

Q. Is the Illinois river at Grafton a safe drinking water in its raw state, in your opinion?

A. It is not.

Q. Is the water of the Mississippi river at the chain of rocks which consists of a mixture of the Missouri, the Mississippi and the Illinois rivers, today, in your opinion, a safe drinking water in its raw state or as treated in the settling basins of St. Louis?

A. According to the present views on water supplies held by engineers and sanitarians, it is not.

11430 Q. How should the water of the Mississippi river at the chain of rocks be treated in order to make it a safe drinking water for drinking and domestic purposes by the citizens of St. Louis if at present it is not a safe drinking water, in its raw state?

A. It should be artificially purified.

Q. In what way?

A. By filtration.

Q. Have you given the question of filtration of the Mississippi river at the intake any consideration?

A. I have given it some consideration.

Q. To what extent, Mr. Hering?

A. I have read a report which was made by a commission of hydraulic engineers upon the water supply of St. Louis to the mayor of the city in 1902.

Q. Who made the report to which you refer?

A. A commission of engineers consisting of Mr. Benezette Williams, George Y. Wisner and Allan Hazen.

Q. In that report to which you referred did your firm have anything to do with?

A. My associate, Mr. George W. Fuller, was asked to consider some features and he made a report which is added

11431 to the report of the Commission.

Q. You have read the report of Mr. Fuller that is published in the document to which you refer in regard to the question of filtering the water of St. Louis as advocated by Mr. Hazen in that report?

MR. JEFFRIES: Objected to as immaterial and incompetent.

A. I have.

Q. What are your personal views and opinions in regard to the treatment of the water of the Mississippi river as it passes by the city of St. Louis at the intake tower at the chain of rocks?

A. My personal views are that this water in order to be supplied to the city of St. Louis for domestic consumption should be purified by mechanical or rapid filtration as the best, most rational and least expensive method of purifying this particular water.

Q. What experience have you had in the filtration of water and the construction of filters for municipalities?

11432 A. I have taken considerable interest in the matter from the time I first visited some European filters in 1881. I was acquainted with Mr. Hyatt who invented the first rapid or mechanical filter and introduced the same in this country, and always anticipated some advantage to be gained from such a method of rapid filtration, and have followed the advances of mechanical filtration ever since. I studied the methods of slow filtration on the ordinary European method and in connection chiefly with the water supplies of Philadelphia and New York, in both of which cases I recommended the slow sand filtration for adoption. I was also asked to pass upon the method of filtration to be adopted at Washington, D. C., in connection with Mr. George W. Fuller and Mr. Allen Hazen, we three making the report. I have gone into the subject of filtration as thoroughly as I know how.

Q. Are you acquainted with the cost of building filter plants?

A. I am.

Q. Are you acquainted with the cost of operating filter plants?

A. I am.

Q. What is your opinion as a sanitary engineer whether it would cost any more to filter the water of the Mississippi river at the chain of rocks, which consists of the combined 11433 waters of the Illinois, Mississippi and Missouri rivers with the sewage from Chicago emptying into the drainage canal and from thence into the Illinois river than it would if such sewage was eliminated from the sanitary drainage canal?

A. In my opinion it would make no practical difference in the construction method or cost nor in the method and cost of operation.

Q. As a sanitary engineer passing upon the quality of the water of the Mississippi river as it passes St. Louis and the chain of rocks, what facts would you take into consideration in passing upon the quality of that water in its raw state?

A. The chief object that would first appeal to me to which I would have to get some satisfactory answer and solution is the turbidity of the water because that affects the manner of treatment more than anything else, and then of course I would also consider the pollution of the river by the number and kind of bacteria contained in the water.

I would also be governed by the hardness of the water or any mineral content of different kinds. I would have to know what the water was, both chemically and bacteriologically 11434 and physically before I would feel that I was completely and satisfactorily solving the problem.

Q. Taking the data which you have introduced in evidence, what help would that data be to you in considering such a problem?

A. These data would indicate to me that first and foremost a filtration of the water was necessary, due to the probability that typhoid bacilli would reach St. Louis to a large extent from the Mississippi and Missouri and to a less extent from the Illinois river.

Q. What consideration would you give to the sewage coming from Chicago?

A. I should give no consideration at all because it was a small factor in the problem. It was too small a factor in the problem to materially affect any recommendation.

Q. In the operation of such a filter plant that would be established to meet the demands of the people of St. Louis for a pure and safe water supply, would the operation of such a plant require a higher degree of skill or more expensive men to manage and operate such a plant with the sewage of Chicago emptying into the Illinois river than it would if such sewage was not present in the Illinois river through the drainage canal?

A. It would not.

(Witness temporarily withdrawn.)

11435

ALBERT S. CRANE,

a witness called on behalf of the defendants, after being duly sworn by the Commissioner, was examined in chief by Mr. Todd, and testified as follows:

Q. What is your name?

A. Albert S. Crane.

Q. What is your business?

A. Civil engineer.

Q. What institution are you a graduate from?

A. Cornell University.

Q. After graduating at Cornell where did you go?

A. I spent the summer of 1891 with Mr. Hering in Europe.

Q. What doing?

A. Visiting sewage purification and water filtration works, principally.

Q. After coming back to this country what did you do?

A. I went to work with the city engineer of Newton, Massachusetts, and occupied various positions from inspector to assistant engineer and finally division engineer. In December of 1894 I went to Washington and was engaged 11436 in the United States Engineer's office on sewerage plans for Fort Monroe.

In April, 1895, I accepted a position as assistant engineer in the Department of Sewers in the city of Brooklyn and remained in that department and the department of city works until October, 1898.

From October, 1898, until March, 1900, I was chief assistant engineer of the Michigan & Lake Superior Power Company.

Q. Where is that company located?

A. Sault Ste. Marie, Michigan.

Q. Briefly, what work did you do at the Sault?

A. The first two years I was on water power construction. The last two years I was chief engineer of the Lake Superior Power Company in charge of the waterworks, electric light plant and mill construction and operation.

Q. Since leaving the Sault what have you done?

A. I have been principal assistant engineer of the sanitary district of Chicago.

Q. Did you prepare the chart introduced in evidence by Mr. Hering under the caption "Sanitary District of Chicago, schematic representation of the self-purification of the 11437 waters of the Missouri, Mississippi and Illinois rivers, between the cities indicated, based upon the longevity of the life of the typhoid bacillus, as found by experiments made under the direction of Hiram F. Mills, the results of which are given in a paper entitled "Typhoid fever in relation to water supply?"

A. I did.

Q. Was this chart made under the direction of Mr. Hering?

A. It was.

Q. Will you state in detail the sources from which you got the information and state facts relating to the method of constructing this chart?

A. The data for the profiles, including the Missouri river, Mississippi river and the Illinois river were taken from a paper published by the Department of the Interior, entitled "Water Supply and Irrigation Papers of the United States Geological Survey, Number 44."

These figures I used entirely in the profiles excepting on the upper part of the Illinois river where other figures were taken in order to make the profile more in detail. These latter figures were taken from a report by L. E. Cooley, 11438 entitled "Waterway from the Lakes to the Gulf" and are part of the archives of the Sanitary District.

Q. Will you state what the distance is from St. Louis to Chicago, and where you get the data for the distance?

A. On page 39 of the report referred to the distance from St. Louis to the mouth of the Illinois river at Grafton is given as 38 miles. On page 60 the distance from the mouth of the Illinois river to the upper dam at Joliet is given as 325 miles. The distance from dam Number 1 at Joliet to Lake Michigan is 38.6 miles.

Q. Will you explain the upper part of the chart, of the plat introduced by Mr. Hering, and upon what you constructed it?

A. The figures on the horizontal line represent days time of the flow of water from the various towns to St. Louis. In the case of the Illinois river they were obtained from actual float

experiments made during the summer of 1903, by Mr. Heilborn, under the direction of Mr. Randolph. The actual time of flow as representing the minimum time has been corrected for mean time of flow. The minimum time flow was taken as .8 of
11439 the mean. 15 days was the quickest time that we could get that float down. We called that 18½ days, or in other words, the actual time was divided by .8.

Q. Why was .8 taken?

A. That has generally been considered to be the relation between maximum velocity and mean velocity in an open stream.

Q. By whom?

A. Prony was the first man that gave that. Trautwine gives that. It is generally conceded by engineers. The time for the Missouri and Mississippi rivers were computed. First the mean discharges of these two streams was obtained on the Mississippi river at Grafton and the Missouri river at St. Louis.

Q. What were they?

A. Being 57,000 and 120,000 cubic feet per second, respectively.

Q. Where did you get that data from?

A. The data were obtained by using the reports of the Mississippi River Commission, entitled "Tabulated results of discharge measurements of the Mississippi river and its tributaries and outlets for the years 1838 to 1898," and plotting these to form a discharge curve.

In the case of the Mississippi river, the average
11440 gauge readings at Grafton was taken for the years 1890 to 1894, inclusive, and then for the Missouri River the years 1895 to 1899, inclusive. After these average stages were obtained the average discharge was obtained directly from the curve.

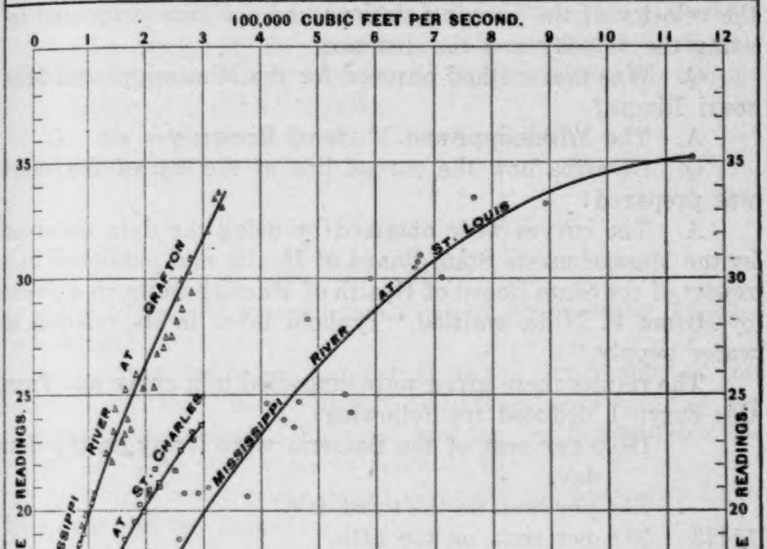
Q. Have you a curve?

A. Yes sir.

Q. Will you produce and make the curve to which you refer a part of your testimony?

A. I will. The chart is as follows:

APPROXIMATE
DISCHARGE CURVES
BASED ON
DISCHARGE MEASUREMENTS
MADE BY THE
MISSISSIPPI RIVER COMMISSION
1838 TO 1898.



11442 Q. How did you figure the time between these points?

A. In the tabulated results of the Mississippi River Commission above referred to are given a large number of discharge measurements, together with the gauge readings, mean and maximum depth, width of the river and velocity in feet per second. The discharges at the various towns along the river were then computed, and by looking in the table the velocity at these towns or a part of them were found. The velocity of the rivers between the different towns was taken as the velocity at the gauging stations and the time computed by using the velocity and the distance.

Q. Was that method pursued for the Mississippi and Missouri Rivers?

A. The Mississippi and Missouri Rivers, yes sir.

Q. Describe how the curved line at the top of the chart was prepared?

A. The curves were obtained by using the data obtained by the Massachusetts State Board of Health and published in a report of the State Board of Health of Massachusetts, in a paper by Hiram F. Mills, entitled "Typhoid fever in its relation to water supply."

The results there given were embodied in a curve and from this curve I deduced the following:

100.0 per cent of the Bacteria were living on the first day.
73.4 per cent. on the third day.
11443 50.8 per cent. on the fifth.
30.8 per cent. on the seventh.
14.1 per cent. on the ninth.
5.2 per cent. on the eleventh.
2.5 per cent. on the thirteenth.
1.6 on the fifteenth.
1.0 on the seventeenth, and
0.4 per cent. on the nineteenth.

Assuming that the number of typhoid bacilli contributed was proportional to the population, the curves were started at the extreme from St. Louis. Working towards St. Louis the results for the first, third, fifth, etc., days were plotted. These curves were plotted for each city in turn.

Q. How was it represented at St. Louis?

A. The results at St. Louis were so arranged that the result for the Illinois River was placed opposite the combined results of the Missouri and Mississippi Rivers so that they might be directly compared.

Q. What does the variation between the Illinois, the Mississippi River and the Missouri River, as indicated upon this chart represent as to the comparative populations at St. Louis, of these three rivers?

A. This would show that the Illinois River has the effect
of a city of 13,000 situated immediately above St. Louis,
11444 the Missouri River of a city of 96,000 and the Mississippi
River of a city of 107,000.

Q. Or a relationship of 13 to 96 and 107?

A. Yes sir.

CROSS EXAMINATION

By Mr. Jeffries.

Q. Where did you get this table of distances on the Illinois River?

A. From the report number 44 of the Department of the Interior, entitled "Water Supply and Irrigation Papers of the United States Geological Survey," and the few figures from the report of L. E. Cooley above referred to.

Q. Mr. Cooley in his report gives 360 miles between Lake Michigan and St. Louis?

A. It comes out 364.7, as I have it here.

Q. From Lake Michigan to St. Louis?

A. Yes sir.

Q. In this chart and these surveys which you have drawn
representing the Illinois, Mississippi and Missouri Rivers
11445 what populations did you take into consideration?

A. The populations of the cities and towns of about 5,000 inhabitants, and over, located on these rivers.

Q. That is immediately on the banks of the rivers?

A. Yes sir, not on the tributaries.

Q. What rivers did you take into consideration on the Missouri River—have you a list of them?

A. Yes sir.

Q. Just name them?

A. Omaha, South Omaha, Council Bluffs—

Q. Have you the population?

A. Yes sir.

Q. Put the whole thing in?

A. Omaha, including South Omaha and Council Bluffs, 154,000

	Plattsmouth	4,964
	Nebraska City	7,380
	St. Joseph	103,000
	Atchison	15,700
	Leavenworth	20,700
	Kansas City	215,000
Q.	That is both of them?	
	A. Yes sir. Independence	6,974
11446	Lexington,	4,190
	Boonville,	4,377
	Jefferson City,	9,664
	St. Charles	7,982
Q.	The Mississippi River?	
A.	Minneapolis and St. Paul, combined,	365,783
	Red Wing	7,525
	Winona	19,714
	La Crosse	28,895
	Dubuque	36,297
	Galena	5,005
	Clinton	22,698
	Davenport, Rock Island and Moline	71,995
	Muscatine	14,073
	Burlington	23,201
	Ft. Madison	9,278
	Keokuk	14,641
	Quincy	36,252
	Hannibal	12,780
	Louisiana	5,131
	Alton	14,210
11447 Q.	Now, the Illinois River?	
A.	Chicago	1,698,000
	Joliet	29,353

Morris	4,273
Ottawa	10,588
La Salle	10,446
Peru	6,863
Spring Valley	6,214
Peoria	56,100
Pekin	8,420
Beardstown	4,827

Q. Where did you get the velocity of the waters in the Mississippi and Missouri Rivers?

A. From the tabulated results of the discharge observations Mississippi River and its tributaries and outlets, published by the Mississippi River Commission.

Q. What year?

A. Years 1838 to 1898.

Q. Published in what year?

A. There are three parts published in 1895, 1897 and 1898 respectively.

Q. Does that include the Illinois River?

A. There are one or two observations in the Illinois River.

11448 There were a few observations at Grafton.

Q. As to the velocity?

A. Yes sir.

Q. You did not use any of the velocities published in the Geological Survey on the Illinois River?

A. No.

Q. Now, do these velocities that you obtain from the Geological Survey represent the velocity of the Missouri and Mississippi Rivers from Omaha and St. Paul to St. Louis?

A. At some points; not at all points.

Q. What points were taken?

A. On the Mississippi River at Winona, Burlington and Hannibal. On the Missouri River at Omaha, Nebraska City, Atchison, Kansas City and St. Charles, those being the only discharge stations.

Q. And those determinations as made by you and which are displayed upon the chart represent conditions which would exist in the event the effects of the sewage discharges into the respective rivers were converted into three respective cities

upon the Mississippi River immediately above the city of
11449 St. Louis?

A. Yes sir.

Q. Now, in what connection did you use the population of the respective rivers with reference to the velocity of the water in those rivers?

A. The populations were plotted on the chart directly above the number giving the number of days distance which they were from St. Louis, the effect of this population decreasing according to the curve plotted from the data on which the chart is based.

Q. Now, assume that the time flow from the mouth of the south fork or south branch of the Chicago River to the city of St. Louis was ten days, how would that effect the result of your determination, and what would be the determination figured on a flow of ten days?

A. It would have the effect of a town of about 160,000.

Q. It would have the effect of a town located upon the Mississippi River, immediately above the city of St. Louis, of about 160,000 population?

A. According to the chart.

Q. And as the velocity increased and decreased from the figures which you have given the results, comparatively speaking, would change at the city of St. Louis?

11450 A. They would.

Q. These floats that were used in making the experiment of the velocity of the water in the Illinois River, could you describe them?

A. I can.

Q. Then just describe them in a plain way?

A. The upper part of the float consisted of two tin segments of a sphere, soldered together, so that the horizontal diameter of the float was six inches and its height 1 1-2 inches. On top of this was constructed a small ring in which a cork and flag were placed. Attached to the lower part of the upper float, by means of brass picture wire, was a hollow cylinder, 8 inches high, and 8 inches outside diameter.

Q. How deep under the surface of the water was the cylinder suspended?

A. The cylinder was generally suspended 2 or 3 feet below the surface. That varied, however.

Q. Did you personally supervise this work?

A. I did not.

Q. What portion of a body of water in a running stream is the most rapid?

A. Generally the part near the center of the stream, and
11451 a little below the surface.

Q. What was the obect in having these cylinders suspended from 2 to 3 feet under the surface of the water?

A. So they would get the effect of the current and not have the wind effect. In other words that they would show the current rather than the wind.

Q. Did the wind effect have any control or influence over the velocity of the cylinders as they passed down stream?

A. It probably had a very slight effect.

Q. What particular place in the Illinois River, with reference to the current on the surface or the bed of the stream did you get the velocity of by means of the cylinder?

A. Generally it was pretty close to maximum velocity.

Q. Is it not a fact that engineers recognize that the greatest velocity in a running stream is about 2 feet underneath the surface, when the stream is about 10 feet deep and that it graduates according to depth upon that basis?

A. I should say between 2 feet and the surface is the maximum.

Q. Why is it that the surface is not taken as the greatest velocity?

11452 A. On account of the wind and the friction of the air.

Q. The whole subject is a good deal a matter of speculation is it not, except that you know that such distinctions exist?

A. Depends upon the stream.

Q. These charts about which you have testified in evidence are the same charts that were testified about by Mr. Hering this forenoon?

A. Yes sir.

REDIRECT EXAMINATION

By Mr. Todd.

Q. If at maximum flood time the distance in time from Kansas City was 3 days instead of 6.8, as shown by this chart, what would it show?

Mr. Jeffries: I object to the question as immaterial.

A. 230,000. That is the effect of the cities on the Missouri River would be that of a city of 230,000 directly above St. Louis.

ALBERT S. CRANE.

ADJOURNED UNTIL 10:00 A. M., FRIDAY, MARCH 11, 1904.

IN THE

Supreme Court of the United States

THE STATE OF MISSOURI
vs.
THE STATE OF ILLINOIS
and
THE SANITARY DISTRICT OF CHICAGO.
} Original, Docket No.

Before
FRANK S. BRIGHT,
Commissioner of the Supreme Court of the United States.

VOLUME 8.

VOLUME 8.

11453 10:00 A. M. Friday, March 11, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

RUDOLPH HERING

resumed the stand for cross examination by Mr. Jeffries and testified as follows:

Q. State exactly when your connection with the Sanitary Commission of the city of Chicago commenced?

A. I started upon my duties on March 28th, 1886.

Q. That was long before any work had begun on the construction of the canal?

A. Yes sir.

Q. The real object of this drainage canal was and is to remove the sewage material from the Chicago River in order to prevent deleterious substances being swept out into Lake Michigan and thereby affecting the water supply of the city
11454 of Chicago, as well as to remove the offensive odors which
arose continuously from the contents of the river, was it not?

A. That was the chief and primary object.

Q. As a matter of fact that was the basis of your being called into the investigation?

A. I believe so.

Q. You reported upon no other proposition, did you?

A. Yes, I did. I reported upon the disposal of the sewage of Chicago by the other methods which were known to accomplish a proper purification or inoffensive disposal of the sewage.

Q. You reported upon nothing except upon methods with respect to the disposal of the sewage of Chicago, and the ultimate protection of the water supply of Chicago?

A. That was all I reported upon.

Q. And in this report you presented two or three means by which this protection could be brought about?

A. Yes.

Q. One of those was the construction of the canal?

A. Yes sir.

11455 Q. Another was the pumping or removal of the sewage from the city upon land adjacent to the city of Chicago, in order that it might then be purified?

A. Immediately adjacent and extending around the southern end of the Lake, yes sir.

Q. And a third was a continuation of the discharge of the sewage into Lake Michigan?

A. Under very much improved conditions, yes sir.

Q. What were some of those improved conditions going with the recommendation as to its discharge into the Lake?

A. They were that the discharge of sewage and the intake for the water supply should be as far apart as practicable. It was proposed, if I remember rightly, to take all the water for Chicago from a point out in the lake opposite what is called Grosse's point. The sewage was to be discharged as far towards the southern end of the lake as practicable. It was also intended to strain and so deprive the sewage of the grosser pollutions when discharged into the lake, so that it would be diluted and therefore in as unobjectionable condition as that method of disposal would make it.

Q. You still recognize that a method of that character would be objectionable?

11456 A. If the sewage were discharged in a raw state at a distance from the water intake, which would necessarily be limited, I would consider that method of disposal not the best possible.

Q. What difference would there be in a discharge of that character directly into the Lake and a discharge into the Chicago River, as it then existed?

A. As it then existed the Chicago River was loaded with an accumulation of organic matter during such times when the flow was very slight. Whenever there was a heavy rainfall or a freshet all this accumulated matter would be carried out into the

Lake and immediately to one of the water intakes of the city. In the method of lake dilution examined there would be a continous discharge and therefore no long accumulation of foul matter which could at once be driven out, and there would also be a very much greater distance between the sewer outlet and the water intake. There would also be the chances during approximately one-half of the year of having the sewage polluted water near the sewage out-fall carried away from the water works intake and therefore the other half of the year would entirely free the proposed intake from possible effects of
11457 such a disposal.

Q. On account of the immense amount of organic matter contained in the Chicago River at that time there was much deleterious substance contained in that case was there not which would be swept into Lake Michigan?

A. Kindly explain what you mean by deleterious.

Q. Substances detrimental to a water supply and injurious to public health?

A. I am not able to tell you how far this matter would be injurious to public health, because that is not a question of engineering.

Q. Is it not a fact that it was so considered injurious to the water supply and detrimental to public health by the engineers who made the report, and that you took such fact into consideration in making your observations and in presenting your report?

A. Engineers take their data on sanitary matters originally from the physicians and sanitarians who investigate such matters and it was their supposition that the discharge of river sediment resulting from the entrance of sewage into the river would be not only offensive but also injurious to health.

11458 Q. You are a sanitary engineer are you not, Mr. Hering?

A. I am a sanitary engineer.

Q. As a sanitary engineer was it not necessary for you to take into consideration the fact that the discharge of sewage of Chicago into the Chicago River and thence into Lake Michigan was a menace, a danger and a detriment to the water supply and to the public health of the city of Chicago at the time this report was made by you?

A. It was.

Q. What was that condition?

A. The condition was that the sewage of Chicago was discharged into Lake Michigan, partly along the shores of the city and partly through the river and when rain fell in large quantities the water from the Chicago River, laden with sewage matters, was forced out into the lake and at times surrounded the then existing intake of the water supply.

Q. Is it not a fact that you took into consideration also the immense amount of filth, sewage and organic matter which had been contained in the Chicago River for weeks and months between the freshets as containing large quantities of
11459 deleterious substances?

A. This accumulated matter was of course flushed out at such times of heavy rainfall and polluted the lake water.

Q. And you took into consideration then the fact that such matter in the Chicago River at that time contained large quantities of objectionable and deleterious material?

A. I did take this into consideration. These were facts that I was speaking about, that this water did go out there and pollute the water supply to such an extent that in my bath room on the north side, not very far from the pumping station, I staid up one night to watch the entrance or the delivery of the polluted water. For instance we followed the river water on the afternoon, until dark, about five o'clock, and then I computed that within an hours' time, approximately, this water would reach the intake crib, then go to the pumping station and be delivered to the residences. It was early in the morning when this foul smelling water ran into my bath tub.

Q. Then in your observations made of conditions existing in Lake Michigan at the time this report was made with
11460 reference to the sanitary conditions of the water in Lake
Michigan at Chicago, you took into consideration the fact that the organic matter contained in the Chicago River and which remained therein for weeks and months, between the freshets, contained substances objectionable to the water supply and deleterious to the public health?

A. I did.

Q. Which, in your opinion, was the more objectionable, the sewage discharged into the Chicago River, and thence into Lake Michigan, or sewage discharged directly from the shores of the lake, under conditions which existed at the time these observations were made?

A. I would answer to that question that in the light of knowledge at the time this investigation was made, I will say, that it was then considered more objectionable to the water supply when the river water reached the cribs than when the sewage discharged at the lake shores entered the same.

Q. Now, why?

A. Because, in the first case there was an offensive odor, clearly recognizable by the senses. The water was not only turbid, but had an offensive odor, whereas the sewage dis-
11461 charged at ordinary times along the Lake Shore did not
affect the water supply in a manner to be distinguished by the senses. Today we know more about the life of the bacilli which are known to cause typhoid fever, and I would hardly know how to answer your question in the light of today's knowledge as to the relative injury to health with special reference to typhoid fever.

Q. Could you express an opinion?

A. No sir.

Q. That is you could not express an opinion upon the present light of sanitary science?

A. I should not like to. It is beyond my sphere of investigations.

Q. Is there a current in Lake Michigan along the west shore, near the city of Chicago?

A. There is, almost at all times.

Q. What is the direction of that current?

A. The current varies with the winds. We found it by investigations during the summer of 1886 that the prevailing current along the shore of Cook County was towards the north, but we recognized from the wind records that it is prob-
11462 able that that result would be reversed during the winter
months, and it was the general opinion of the crib care taker, who was located out in the lake, that the currents were about evenly divided during the year.

Q. Do you know anything about the velocity or rapidity of that current?

A. That current sometimes is observed, if I remember right, to be as much as 2 and 3 feet per second, but generally, of course, less.

Q. How much would that be per hour, figuring at 2 feet per second?

A. That would be 7,200 feet.

Q. That would be more than one mile per hour would it not?

A. Yes sir.

Q. Practically 1 1-3 miles per hour?

A. Yes sir.

Q. Do you know how far the city of Milwaukee is situated on the shores of Lake Michigan from the city of Chicago?

A. I am making a guess if I say 90 miles.

11463 Q. Assuming that the current in the lake, when flowing from the north to the south, makes a velocity of 2 feet per second, how long will it require the water in the lake to flow from Milwaukee to Chicago, the same being a distance of approximately 90 miles?

MR. TODD: I object to the question on the ground it is not proper cross examination of anything that has been brought out on direct, and for the reason that it is incompetent, irrelevant and immaterial.

A. If I understand you right, 70 hours or 3 days.

That is figuring it 1 1-3 miles per hour, but if I may state I do not admit this is a possible condition, because I never knew that this current had such a rate, and that such a rate would be maintained substantially or constantly for three day.

Q. Assuming that typhoid bacilli are discharged into Lake Michigan from the sewers of Milwaukee, and assuming that there is a current flowing past the city of Milwaukee to the south, with the velocity of 2 feet per second, which velocity is maintained for a period of three or four days, is it not a fact that such typhoid bacilli would reach a point in Lake Michigan opposite the city of Chicago?

11464 MR. TODD: I object to the question for the reason it is not proper cross-examination, for the additional reason that the assumptions contained in the question are not proven in evidence, and for the further reason that it is incompetent, irrelevant and immaterial to the issues inovlved in this case.

A. With the assumptions you make I can not answer otherwise than that they would, but it is hydrographically impossible for such a current to flow from Milwaukee to Chicago intake.

Q. Now, why is it impossible?

MR. TODD: I object to the question for the same reasons as heretofore stated to the previous question.

A. Because the water in the lake does not move near the shores in a parallel direction to those shores. There are cycloidal motions and the water passing the Milwaukee sewage outlet would be so dispersed, even though the winds were favorable to a general southern current, that the particular water from the Milwaukee outfalls would not reach the Chicago intake for, to make a rough guess, weeks and possibly months.

11465 Q. Is it not a fact that sanitary engineers must, in their work, take into consideration the longevity of pathogenic bacteria contained in sewage which is discharged into a stream or body of water from which a water supply is taken?

A. Since the longevity of such disease germs has become known it is the duty of the sanitary engineer to consider the question.

Q. In your opinion as a sanitary engineer, taking into consideration your experience in dealing with sanitary questions involving engineering features, and from what you have learned in this connection, how long will pathogenic bacteria live and exist in the waters of a running stream when discharged therein from the sewers of a city?

MR. TODD: I object to the question for the reason it is not proper cross-examination of anything that was brought out in chief, and therefore incompetent, irrelevant and immaterial.

A. When I entered into the study of this case the best information that I was familiar with regarding the longevity of the typhoid bacillus, which is the most important one to consider in cases of this kind, was that contained in the reports of

11466 the Massachusetts State Board of Health and which I used in preparing the chart entitled "Sanitary District of Chicago, schematic representation of the self-purification of the waters of the Missouri, Mississippi and Illinois rivers between the cities indicated," etc.

Since having been engaged on the case I have become acquainted with similar investigations which have recently been made by witnesses in this case, which information is much more exact and practicable and in accordance with actual facts, in my opinion, than the Massachusetts experiments. Had I asked this diagram or this chart to be prepared later I should have used the later and better information contained in the recent testimony in this case.

Q. Generally speaking, Mr. Hering, taking all the observations of bacteriologists and sanitary scientists the world over, what in your opinion is the longevity of pathogenic bacteria coming from the sewers of a city when discharged into a running stream?

MR. TODD: I object to the question for the reasons already stated in my former objections.

A. I consider that every disease bacterium has presumably a different length of life under the same conditions, and 11467 presumably also under different conditions, and as I have not studied concerning any other bacteria than the typhoid bacillus, I could not make such a general answer.

Q. As applicable to typhoid bacillus what would you say?

MR. TODD: I object to the question on the same grounds as heretofore stated.

A. As applicable to the typhoid bacillus my opinion is that particularly with reference to this case the experiments made by Doctors Russell, Jordan and Zeit would guide my opinion on this question.

Q. As a sanitary engineer would you consider a water as being free from typhoid bacilli contained in a river at a given point when you knew that there was a city located upon that river within from four to six days flow, although bacterial observations had been made as to the longevity of the typhoid in that water, the results of which showed that their longevity was limited to two days?

A. As I have already stated in my opinion every surface water supply should be filtered because of the many uncertain elements controlling the sanitary condition of this water, and I would therefore consider such water, under the conditions you state, only with the proviso that it be filtered. The fact 11468 of the life of the typhoid bacillus being two days or twenty days would not cut much figure in my practical recommendation.

Q. Would you consider the water stated in the last question as being free from typhoid bacillus from the city mentioned in that question, which contained 1,600,000 people?

A. As a sanitary engineer I would not be able to answer that question because I would have to take this information from somebody else.

I will further say that if there was an absolute guarantee that a water supply was free from all disease germs I would then state that so far as the water pollution was concerned I should not insist upon filtration, but we are not sure that many disease germs, including typhoid, are not carried by the winds, by air, by insects—in fact, we know that they are so carried, therefore, as in the recent status of an important case, although the evidence indicated an almost impossible pollution by typhoid bacilli, I should still insist that the water be filtered as a safeguard to public health.

Q. If it is a fact that you must depend upon absolute assurance from others as to the presence or non-presence of pathogenic bacteria in a water supply, what then is the necessity of obtaining the opinion or recommendation of a sanitary 11469 engineer upon the sanitary condition of a water?

A. A sanitary engineer is employed for the practical purpose of carrying out sanitary works with the funds of the people. The engineer is a medium between the sanitarians and the money of the people. He must advise a work which is reasonable, economical and at the same time guard the people against all reasonable dangers in a sanitary way. His judgment, therefore, must be independent, and he takes into consideration all the work done by the chemists and bacteriologists and weighs this evidence in the light of the financial condition of the city which employs him, and makes that recommendation which, in his opinion, is best under the circumstances.

Q. As a matter of fact is not the work detailed in your last answer the work of a civil engineer and work which a civil engineer may execute as well as a sanitary engineer, as defined in that answer?

A. The words "civil engineer" is generic. It comprises the work of sanitary, hydraulic and other engineers. If you mean a purely constructing engineer, then I admit that the constructing engineer pays no attention to anything about the scientific purpose of his works. Whether they answer their
11470 work or not is only secondarily his province.

My own work in this country has been to take into consideration all the progress that has been made in matters where the engineer must take such progress into consideration in designing his works, and by that progress in this particular instance I mean the influences upon public health.

Q. Mr. Hering, is there any instance in your whole career as a sanitary engineer, or an instance coming under your observation as to the work of other reputable sanitary engineers or sanitary scientists where the water in a running stream has been recommended as free from the typhoid bacilli of a large and populous city existing on that watershed with a stream velocity of from 10 to 20 days?

A. Without filtration I do not know of any case exactly answering your description.

Q. The table prepared by you, or used by you, rather, giving the results of the experiments of Hiram T. Mills on the longevity of the typhoid germ is the one that you have heretofore used in your experiments and work as a sanitary engineer?

A. Whenever I was called upon to consider the question of longevity of the typhoid bacillus I have had those Massachusetts experiments in mind.

11471 Q. Is it not a fact, Mr. Hering, that you, as a sanitary engineer, when called as a member of a commission or as a consulting engineer have invariably been called upon to give an opinion with reference to the presence or non-presence of deleterious substances contained in the water?

A. No, sir.

Q. And that you have taken such observations into consideration in expressing your opinion or making your recommendations?

A. Whenever that question was pertinent, I, of course, always gave it consideration.

Q. Mr. Hering, what is it that enters into the cost of a filtration plant and the precautions that are to be used in connection with its operation as applied to the character of the water that is to be filtered?

A. The first question usually related to the turbidity of the water, that is as to the amount of suspended matter carried by such water, because the system of filtration to be recommended largely depends upon the turbidity of the water. The next chief question relates to the relative expense 11472 and the topography, the conditions, the availability or non-availability of sand, which sometimes throws the scale one way or another in deciding upon the method of filtration to be adopted.

Q. In the construction of a filtration plant do you as a sanitary engineer take into consideration the sources of pollution, of infection, of substances deleterious to public health in the construction of that filtration plant which substances and sources of pollution exist upon the river above the point where the water is to be filtered?

A. I always take those matters into consideration and have in some instances made what is called a sanitary survey of the entire watershed which yields the water to be used.

Q. In the event a filtration plant was established for the purpose of filtering the water of a certain city, and that at some point above that city a typhoid epidemic should be prevalent, why has it been deemed necessary for the management of the filtration plant to use extra precautions during such epidemic?

A. The running of a filter plant, like the running of any plant, can be somewhat variable, owing to the fact that human beings are required to take care of the management. When there exists a special danger, in that instance, as well as in all other instances where danger threatens a community or a 11473 smaller body of persons extra precautions are taken to avoid anticipated possible trouble. It is quite natural, therefore, and if I should manage a filtration plant myself, I should give the orders myself, that if a known epidemic exists there should be every reasonable precaution taken for special care to be exercised during that period.

Q. Is there an artificial filtration plant in existence which removes 100 per cent. of the bacterial contents of the water?

A. In the records which are published, and which I have seen, there are not infrequent ones where the bacteriological results give a removal of 100 per cent. of the bacteria. I remember seeing those in Europe and I believe also within a few weeks ago in Philadelphia.

Q. What is the cause in the variation in percentage of bacterial removal by these filtration plants?

A. The cause is both to be sought in irregularity of construction and irregularity of operation. It is impracticable if not impossible to make a perfect construction and it is likewise impracticable to demand of the average laborer or artisan or inspector or superintendent an absolute adherence to perfect conditions. 11474

Q. And as the degree of precaution in the management of the filtration plant increases so also the percentage of absolute removal of bacterial contents in the water is approached?

A. Theoretically I will admit the truth of that position, but practically I should say that in the ordinary operation of filter works, particularly throughout Europe where they have been managed for so many years, so far as we know typhoid fever germs have been entirely excluded. The remnant of cases that still appears in those cities is due to other causes than those of water pollution. It has been found in Europe as well as in this country that after the introduction of filter plants the typhoid fever rate has dropped generally to about one-fourth of the rate that previously existed. Some cities more and some cities less.

Q. Those cities which you have just referred to have slow sand filtration plants, have they not?

A. They have.

Q. In the construction of a filtration plant is it not a fact that sanitary engineers take into consideration the extent of the infecting material discharged into a stream above in determining the character of the plant to be recommended?

11475 A. We do take that fact into consideration.

Q. In recommending the construction of a filtration plant for the filtering of a water supply of a city which is taken from a running stream sanitary engineers would recommend the use of larger quantities of sand, if it be that character of a plant, where the water of a river was subjected to the sewage of a city of 100,000 population than if such waters were subjected to the sewage of a city of 1,000 population, would they not?

A. The population would cut no figure in my mind. We would, under practical conditions, possibly recommend one system of filtration for a highly polluted water when we would be satisfied with another system of filtration in a very slightly polluted water.

Q. Polluted or infected water?

A. In this case it is either polluted or infected water.

Q. What would be the difference in the character of the filter plants in the two cases mentioned in your last answer?

A. My personal opinion, not speaking for the profession in general, when the water is highly polluted and infected I should prefer the slow filters to the rapid filters, for the reason that the chances for infection passing the slow filter 11476 would be very much reduced as compared with the chances of passing through a rapid filter. For the same reason that I would rather be on a slow moving train than on a rapidly moving train, if this train met with an accident. It is always possible in any public work to have something go amiss, although we try to make such works upon which not only a large expense but also the health of people depends as nearly as practicable what we call fool proof.

Q. The slow sand filtration plants are more expensive than the others, are they not?

A. As a total expense generally not, sometimes less expensive but sometimes more. The facts are these: The slow sand filter almost invariably costs more to build but less to operate than the rapid or mechanical filter. By adding the interest on the investment to the cost of operating expenses the two methods cost very nearly the same, but in some instances where sand in large quantities is not readily available but must be brought from afar and where the territory is not suitable for large extensive beds, there the mechanical or rapid method is usually found more economical.

Q. Assuming, Mr. Hering, that over the conditions that existed in 1900 at St. Louis, since that time a city con- 11477 taining a population of 160,000 has grown and been built on the Mississippi river immediately above the city of

St. Louis, at the intake tower at the chain of rocks, would not conditions brought about by the discharge of the sewage from this city into the Mississippi river be considered in an item of using extra precaution, greater responsibility, more accurate and perfect means of operation in the construction or recommendation of the construction of a filter plant for that city than if such a city did not exist?

A. I should say there would be a necessity for as careful a management as is practicable in such plants, and the filter plant should be so constructed and operated to allow of as careful an operation as is practicable.

Q. Now, assuming that at all times the filtration plant thus constructed at the city of St. Louis did not remove all of the pathogenic bacteria, that the percentage of removal varied from day to day, week to week and month to month—assuming that the removal of pathogenic bacteria from the water ran in the same proportion, that is that the percentage of the removal of such bacteria ranged at different rates from day to day, week to week and month to month. Under those assumptions is it not true that a greater number of pathogenic germs would pass through the filtration plant with a city of 160,000 population existing upon the Mississippi river immediately above the chain of rocks and the intake tower of the St. Louis waterworks than there would in the event that such city was not so situated upon the Mississippi river, under conditions in both instances which existed at St. Louis prior to 1900? 11478

A. If your assumptions are correct I will be obliged to answer yes, but the conditions are such which would influence my recommendations as a sanitary engineer regarding the water supply of that city. I question very much whether I would put a filter plant immediately below so large a city, receiving the sewage of the city.

Q. Where would you put that filtration plant?

A. I would first look for another source of water supply.

Q. If possible you would put it above the city mentioned in the question, would you not?

MR. TODD: I object to the question on the ground that no such city as assumed in the question exists, and for the reason that the assumption of such a city does not simulate

11479 conditions that obtain at St. Louis at the present time.

A. I could not answer that question without knowing the local conditions.

Q. If conditions were such that you would recommend the filtration plant at the chain of rocks, without the city of 160,000 population being located immediately above, would you not consider that the filtration plant be placed above said city in the event it so existed, conditions being equal, in the event it was possible to extend it above said city?

A. If you are speaking about the chain of rocks, you are speaking about St. Louis?

Q. Yes, sir.

A. And my knowledge of the conditions there would lead me to recommend no change in the intakes of the St. Louis waterworks, under the existing local conditions.

Q. Mr. Hering, assuming that prior to 1900, a recommendation was made for the construction of a filtration plant for the water supply of the city of St. Louis at the chain of rocks, that before that plant was constructed a large and populous city of 160,000 grew up on the Mississippi river immediately above the chain of rocks, you would recommend that the location of the filter plant be changed to a point above this city which has gone up since 1900, if it was possible to do so, would you not? 11480

MR. TODD: I object to the question for the reason that no such condition as is assumed in the question can, does or will exist at the city of St. Louis, and the hypothesis sheds no light on the issues in this case.

A. My answer would be as above that I would be obliged to look into the local conditions before I could answer such a question.

Q. Under the assumptions contained in the question, taking into consideration no other element would you consider that the filtration plant remain as first located by you?

A. I must say the same thing, that I would be obliged to know the local conditions, and I will give you an instance.

Q. Mr. Hering, does a—

MR. TODD: He should be allowed to answer.

11481 Q. Assuming, Mr. Hering, that the dejecta from the typhoid patients which ordinarily exists from one end of the year to the other from a city containing a population of 13,000 people, be deposited in the Mississippi River immediately above the city of St. Louis, that prior to the existence of this discharge a recommendation had been made to construct a filtration plant at the city of St. Louis at the chain of rocks, this dejecta being deposited in said stream 38 miles above the chain of rocks, if it were possible to do so, would you not change your recommendation and recommend the establishment of the filtration plant above the place or point of discharge of the dejecta from the typhoid patients above stated?

A. Under the conditions you state I would not, and if I can now instance the case to which I had reference a moment ago I will say that two large cities, adjoining each other so that you do not know when you pass from one to the other, and both cities situated on one of the largest rivers of Europe, near its mouth, both discharged all their sewage into this stream, the upper one which is Hamburg, having a population of one million, or thereabouts, both cities on this tidal stream
114682 where the sewage of the lower city, Altona, is likely to
reach Hamburg and the sewerage of the upper city, Hamburg, is likely to reach Altona. In both cities the water supply is filtered and with excellent results, and under those conditions being well familiar with both cities for many years I would not, if I had an opportunity to do so, recommend any other method of water supply than the river water after it has been filtered.

Q. Assuming, Mr. Hering, that a certain per cent. of the pathogenic bacteria pass through the filtration plant into the water supply, would not that percentage increase on account of the discharge of the typhoid dejecta from typhoid patients in the city of 13,000 population, situated upon the Mississippi River, immediately above the intake of the St. Louis water works—the percentage that passed through the filter would increase?

A. They might. I do not know. The difference would probably be small compared with the material difference in the exclusion of bacteria even if such a city did not exist.

Q. Taking the water in its raw condition what effect would the typhoid dejecta of the typhoid patients in a city of 13,000 population, situated immediately above the city of St.

11483 Louis on the Mississippi River have upon the sanitary condition of that water supply?

Mr. Todd: I object to the question for the reason that no such city as described exists, as the only cities that exist immediately above the intake of the St. Louis water works are the towns of Alton and St. Charles, and approximate the population assumed.

A. I do not consider myself as an engineer competent to answer that question. If I wished to know it myself I would consult a bacteriologist well versed in such matters.

Q. From your experience as a sanitary engineer and in conferring with others of the profession and based upon the information which you possess, and upon which you testified as a sanitary engineer, taking into consideration the history of sanitary science, its development, the growth of bacterial science and of the science of chemistry and all that pertains to the pollution and infection of water supplies, what effect would you say that the deposit of the typhoid dejecta from the typhoid patients of a city of 13,000 population have upon the sanitary condition of a water supply when deposited in that water supply immediately above the intake, that supply being taken from a running stream?

11484 A. You ask me as to the effect that such a discharge would have?

Q. Yes sir?

A. And then I must repeat what I said before, that as an engineer I am not able to tell you what such effect would be. I would get such information, if I wanted it myself, from others especially qualified to know what such effects would be.

Q. Would it in your opinion as a sanitary engineer, taking into consideration your knowledge of the science of bacteriology and chemistry as applied to sanitary science, as stated in your qualifications of yesterday, have a deleterious or wholesome effect upon that water supply?

A. As a sanitary engineer and taking into consideration what I could learn from others regarding the question of effect, I would state that under the conditions assumed that it would make no difference with me in my recommendations, regarding a plant to be constructed for St. Louis.

Q. But particularly with reference to the sanitary condition of the water in its raw condition, what effect would it have? In other words, would such a discharge have the effect of rendering that water in its raw condition in a less wholseome state or render it more unwholesome?

A. Irrespective of the filter?

11485 Q. Irrespective of the filter—we are speaking of the water in its raw condition?

A. Then I would say that presumably the more infection contained in the water the less wholesome it would be as a self-evident proposition.

Adjourned until 2:00 p. m., same day.

11486 Met pursuant to adjournment at 2 p. m., March 11th, 1904.

Present, the Commissioner and same counsel representing the respective parties.

RUDOLPH HERING

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Mr. Hering, one of the methods suggested by you in your report was to remove the sewage of Chicago from its water supply by conveying it upon land situated south of the city, wasn't it?

A. It was.

Q. Did you make any estimate as to the cost and amount of power necessary for the elevation of sewage upon this land?

A. I did.

Q. State whether or not a power plant constructed upon the canal at Lockport would create sufficient power to make this elevation?

MR. TODD: I object to the question as not proper cross-examination and for the further reason it is incompetent, irrelevant and immaterial to the issues in this case.

A. I took no account of such power, in regard to lifting the sewage, but estimated the usual cost for pumping the same, and in doing this I considered the fact that if there were such

power created by the waters of the canal, that this could
11487 be sold at a price which I believe is indicated in the report, or at least was in our notes from which the same was prepared, and that therefore the same amount of expenditure in one case would be balanced by the receipts in another. Therefore, the expenses would be practically the same whether the water was pumped by coal or by water power.

Q. As a matter of fact, Mr. Hering, could not the power generated by the plant mentioned by you in your report be used to facilitate the elevation of the sewage of Chicago, upon the land referred to by you in your report?

MR. TODD: Object to the question for the reason that it is not proper cross-examination and for the further reason it is incompetent, irrelevant and immaterial to the issues involved in this case.

A. It could be used, but on account of the great distance which it would be necessary to transport the power there would be a material loss in the same and that branch of engineering was not sufficiently developed at the time to enter into such a subject further than we did.

Q. Is it not a fact that the same loss would be entailed in the sale of the power as well as in its use in the particular
11488 matter mentioned?

MR. TODD: Object to the question for the reason it is not proper examination and the additional reason that it is incompetent, irrelevant and immaterial to the issues involved in this case.

MR. JEFFRIES: Is it not a fact that the same loss would be entailed in the sale of the power as well as in its use in the particular manner mentioned, and the extent of this loss would depend upon the distance of the point where the power has to be utilized from the power plant?

MR. TODD: I object to the question for the reasons stated and for the additional reason that there is no water plant or power plant.

A. The loss would depend upon the distance of transmission; the greater the distance the greater the loss.

Q. What is the percentage of loss in distance?

MR. TODD: I object to the question for the same reason.

A. I am not an expert electrical engineer and cannot tell you.

MR. JEFFRIES: Q. Why was not the proposition to continue the discharge of the sewage of Chicago into Lake
11489 Michigan recommended in preference to other propositions and especially preferable to the one which was adopted?

A. The discharge into the Illinois river under the conditions stated in the report was recommended because of the assurance that the sewage of Chicago would be sufficiently diluted to avoid offensiveness along the river at any point, and also to do no other injury, while a discharge into Lake Michigan, ascertained to be much more expensive, was at the same time surrounded with some doubt as to the character of the dispersion of the sewage by the lake currents.

The discharge into the Illinois river in the first place assured a positive removal of the sewage from Lake Michigan, the only possible source of Chicago's water supply, and the dilution which was recommended was so large that no objectionable results could be seen. The greater economy of this project and the incidental value of the works, as a navigable waterway between the lakes and the Mississippi river, made the project, while safer from a sanitary point of view, also less expensive from a financial point of view, and of greater
11490 advantage from a commercial point of view.

Q. Were you not called upon to investigate the commercial side of the cost?

A. No, sir; but this was an incidental question which entered into the consideration.

Q. It was a very remote incidental consideration, was it not?

A. It was not remote while considering the Illinois river project. It was remote, if the business project had appeared to be the purification of sewage on sand around Lake Michigan, but considering the proposition of dilution, which meant practically the establishment of a large river between the Great Lakes and the Mississippi, it would have been unfortunate, had not this large river been so designed and constructed that it would be of the greatest use to the country. For that reason, the Sanitary District Canal was built almost on a level, so as to allow the

water to assume a velocity not inconsistent with the demands
of navigation. If it had not been for that consideration it would
have cost less money to have built a tunnel from Lake
11491 Michigan directly to Joliet, giving the water a very much
larger velocity, and consequently the channel a much
smaller cross-section.

Q. But the dilution would not have been as great?

A. Assuming the dilution just the same. I might add that a proposition was considered of taking the sewage to Joliet without such dilution and below Joliet, purifying the sewage and discharging the effluent into the Illinois river, but this project was found to be so much more expensive than the others under consideration at that time in view of the limited time and funds at our disposal it was not considered in detail.

Q. That even could be done yet, could it not?

A. That could be done at a very large expense, which I approximated in a general way.

Q. But it could be done?

A. It is physically possible. It would represent, if I remember rightly, an investment of nearly eighty millions of dollars.

Q. In making these examinations, or these observations
upon which this report of yours is based, did you reach
11492 the conclusion that the sewage of Chicago could not
be discharged a sufficient distance in Lake Michigan so
as not to effect the water supply, or that the water supply could
not be extended and drawn from the lake at a sufficient distance
to be free from the sewage pollution of the city of Chicago?

A. The question was involved in sufficient doubt and the expense was so much greater than the project recommended, that in view of the limited funds and time, it was not considered necessary to remove such doubtful points.

Q. Then you mean to say, that an expenditure of $50,000,000 that with that amount the water intake cribs could not be extended a sufficient distance in lake Michigan so as to be free from the contaminating effect of Chicago sewage?

A. The question of extending the intakes ten to 20 miles into the lake was considered, but the means available at that time for estimating the cost, in connection with all other con-

siderations that I have mentioned, did not allow us to get sufficient information to cause us to reduce the estimates
11493 of costs which were given, which estimates must exceed
the cost of the proposed object, and the assurance of the direct and indirect advantages of the lake disposal were not as great as the assurance of the disposal into the Illinois river diluted as recommended.

Q. You mean to say, Mr. Herring, that there were no means at that time of determining from the standpoint of a sanitary engineer the exact cost that it would require to extend the intakes of the Chicago water-supply from 20 to 22 miles into Lake Michigan?

A. I would not say that such an estimate could have been made within 20 per cent or more of the probable cost. We have the example in the construction of the 4 mile tunnel in Chicago and of the construction of a 4 mile tunnel at Cleveland, both of which cost very much more than the estimated amount. But it is not altogether the cost, it was the doubt which necessarily prevailed in our minds, after the current observation as to whether the Chicago sewage would be transported by the current, so as to free the water delivered to the city from pollution.

Q. And that conclusion was reached by the commission
11494 regardless of where or how far into Lake Michigan the
intakes might be extended? A. No, it was reached after a general consideration of all the information available to the commission, at that time.

Q. And, in addition to those facts, you also considered the necessity of getting rid of the offensive organic material deposited in the Chicago river of the City of Chicago?

A. Certainly. The deposit of material in the Chicago river at that time was the accumulation of many years. It was not considered that there could be such a deposit to any extent after the Drainage Canal would be in operation. Therefore, as soon as these deposits had been removed by dredging them, as they were then dredging them, or in some other way, the condition of the river would be much better and would practically be free from this accumulated deposit which would be constantly taken up and carried down with the water into the Canal.

Q. Then, during these freshets which you speak of, occur-

ring in the Chicago river, in which you spoke of this
11495 forenoon, all of the deposits were not washed out thereby into Lake Michigan, were they?

A. I think not.

Q. Mr. Hering, then the result of this whole transaction is that by the opening of the Canal, the city of Chicago has avoided the deposits of organic matter coming from the sewers of Chicago, and manufacturing wastes in the city of Chicago, in the Chicago river, and while such matters are not now deposited in the Chicago river, they are carried by the waters of Lake Michigan out of the river into the Canal and thence into the Desplaines and the Illinois river?

A. There is no doubt of that.

RE-DIRECT EXAMINATION BY Mr. Todd.

Q. In the operation of a filter, what relationship do the bacteria bear to matters in suspension?

A. In very turbid waters, such as in the southern part of our country, and Missouri, it has been found that the chief desire of the engineer, in order to produce a satisfactory water, is to remove the turbidity, that is, the suspended matter in the water.

It has been found that if a very turbid water is thoroughly
11496 clarified, that incidentally thereto, the bacteria are also removed; that therefore, if we give consideration in the construction of works to the economical and complete removal of the suspended matter which caused the turbidity, we accomplish all that is desired, even to the removal of the bacteria, and, including the diseased bacteria, judging from the effects of such filters upon the occurrence of such disease.

Q. Is there any validity to the assumption that a city of 13,000 inhabitants exists upon the Mississippi river immediately above St. Louis, based upon the chart which you have introduced in evidence.

MR. JEFFRIES: I object to the question for the reason counsel has no right to impeach or discredit the testimony of his own witness, or to impeach or discredit the testimony introduced by himself.

MR. TODD: In reply to counsel I will state that there is no intention on the part of counsel for the defendants to impeach the testimony of any witness for the defense, but on the contrary to shed light upon the charts which it is evident from the questions asked by counsel of this witness, that he himelf has 11497 not demonstrated that he has a clear idea of what these charts purport to convey, and that it is for the enlightenment of counsel and the court, and not for the purposes of the impeachment of any witness.

MR. JEFFRIES: I object to counsel stating what his object is or may be, and I ask that under the rules of evidence he be bound by the questions that he has asked and the answers that he has solicited from this and other witnesses in this respect, and still insist that the question is irrelevant and incompetent because it is in effect an impeachment of his own witness and discrediting his own testimony.

MR. TODD: If counsel's conclusions are correct I know of no interest in this litigation that would more cheerfully welcome the casting discredit upon the defendant's witness than counsel himself. And I submit that the very fact that he urges this objection is a refutation of his reasons for the objection.

A. The information which the chart was intended to convey in my opinion was the relative amount of infection that would be contained in the three rivers upon reaching St. Louis, irrespective of any population residing immediately above St. Louis.

11498 MR. TODD: And this relationship is expressed by the numbers 13, 96, 107, for the three rivers respectively?

A. Yes sir.

RE-CROSS EXAMINATION by Mr. Jeffries.

Q. Now, in this chart which you have just referred to in your re-direct examination is included the population of the city of Chicago? A. It is.

RUDOLPH HERING.

ADJOURNED until Monday, March 12th, 1904, 10:00 a. m.

10:00 A. M., Saturday, March 12th, 1904.

11499 Continuation pursuant to adjournment.

Present the Commissioner and same counsel representing the respective parties.

PROF. GEORGE DOCK,

a witness called in behalf of the defendants, after being duly sworn by the commissioner, was examined in chief by Mr. Todd and testified as follows:

Q. What is your name?

A. George Dock.

Q. What is your business?

A. I am a physician and teacher of medicine, and have the Chair of Theory and Practice of Medicine in the University of Michigan.

Q. How long have you been connected with the University of Michigan?

A. This is my 13th year.

Q. Where were you educated before taking up the study of medicine?

A. In Harrisburg, Pennsylvania.

Q. Did you graduate from that institution there?

A. I graduated in medicine at the University of Pennsylvania. 11500

Q. What year?

A. In 1884.

Q. After graduating, what did you do?

A. The next year I spent in a hospital in Philadelphia, St. Mary's Hospital in the worst typhoid fever district of Philadelphia, in Kensington, Philadelphia, where I saw a good deal of typhoid fever and I spent a year at that.

Q. What were your duties there?

A. I was an interne, and had charge of various classes of patients, and part of the time I was in the dispensary where I had to examine a great many patients and go out and see a great many patients in houses.

Q. What next did you do?

A. After that I went to Germany, to prosecute my studies in medicine, internal medicine, especially; I went to Leipsic at that time, which was very full of typhoid fever. My experience in Philadelphia, where I expected to settle, had increased my interest in the disease and I paid a great deal of attention to typhoid there. That was before they had improved the water supply and sewage of Leipsic, and there was a great deal there. I spent part of the year there, then I went to Berlin and 11501 saw a great deal of typhoid fever there. I studied the bacteriology of it in both those places and spent altogether two years over there, in the study of pathology and internal medicine.

Q. At what institution?

A. At the Universities of Leipsic, Berlin, Vienna, and in the Pathological Institute in Frankfort.

Q. After getting through there what did you do?

A. I went back to Philadelphia, where I was assistant to Dr. Osler, and Dr. Musser, in the University Hospital. I also had charge of the part of the Medical Dispensary in the University of Pennsylvania, and practiced there too. I saw a great many cases of typhoid fever, and there I began the study of malaria. Dr. Osler was then the first man in America, studying malaria. He had a great many cases brought in to him from the outside. I spent a great deal of time working on them and became very much interested in the practical diagnosis of malarial disease.

Q. Who is Dr. Osler?

A. He is now Professor of Medicine at the Johns Hopkins Hospital.

Q. Then what did you do?

11502 A. After that I had an offer to go down to Galveston, Texas, to teach medicine and pathology. I went there chiefly on account of my interest in malaria. I went down there and stayed three years. I was professor of pathology in the Galveston Medical school and physician to the Hospital connected with the medical school and the last two years I was there, practiced. In Galveston I found they were diagnosing practically no typhoid fever at all and yet I saw lots of typhoid fever patients there. I was able to see that cases that were diagnosed as malaria and typho-malaria were typhoid fever, and my experience showed me that none of these cases had malaria. I did, however, see fatal cases of malaria. They were all cases that either came from the Tropics, Nicaraugua, or Panama, or else cases from the interior of Texas, where they occasionally have very severe forms of malaria. I became very much interested in the practical diagnosis of so called malarial diseases, continued malaria, and various local names that are given to this disease, and did some work on it, wrote an article, read a good many papers on the subject before medical 11503 societies.

On one occasion I made an offer to visit any patient having typho-malaria, or continued malaria, and examine the blood free, in order to settle whether it was malarial fever or could be diagnosed as typhoid. I never had occasion to have my offer accepted.

Q. Well, in Texas did you study the characteristics of malarial fever as they obtained in the southwestern part of the country?

A. Yes, very extensively.

Q. How extensively?

A. Well, I saw many cases and examined them all very thoroughly, wrote several papers on the subject that have been widely quoted and became looked upon as somewhat of an expert in malarial diseases.

Q. After leaving Galveston what did you do?

A. I went to Ann Arbor, and there I had the same experience I had in the south. I found that the doctors were diagnosing many cases of typho-malarial fever. My interest, of course, was still alive. I examined many of those cases post mortem as well as in life, and I was able to show the same thing, cases that were diagnosed as typho-malarial and con-
11504 tinued malarial were all cases of typhoid fever. In Michigan I did not see any fatal cases of malaria at all. Since then I have examined a great many cases every year. I have cases sent in under the diagnosis of typho-malaria or some similar name and I have frequent occasion to clear up the diagnosis.

Q. Have you acquainted yourself with the characteristics of malarial fever as they occur in the Mississippi valley?

A. Yes sir.

Q. What attention have you given to the study of malaria and typhoid as it occurs in the Mississippi valley?

A. Well, now, the Mississippi valley is of course a great point in both of these diseases, and in studying the features of typhoid fever and malaria I studied the conditions and talked with many doctors throughout there, and when I lived in Galveston I always came through St. Louis two or three times a year and usually stayed over a day and had opportunities for looking around the town from a malarial standpoint. This with the eye of a malarial searcher. I was looking for malaria everywhere.

Q. Are you acquainted and have you information in regard to malarial diseases as they occur in cities along the Mississippi river? 11505

A. From conversations with doctors, not from my own observation.

Q. Have you given any attention to the questions of malaria in St. Louis and have you formed any opinion about the character of malarial fever in the City of St. Louis?

MR. JEFFRIES: I object to the question for the reason the witness said he had no experience of his own, but relied upon what others told him and therefore anything he might say would be based upon hearsay testimony.

A. Yes, as I say, in going through St. Louis I was always interested in the question of malaria. I examined the outskirts of the city, and formed the opinion that I have, which was not based upon examinations of my own, of patients but I had some correspondence with doctors in St. Louis, because I was writing on malaria, and the doctors there wrote me as to their methods of examining, and various questions connected with malaria, and I gathered some information that enabled me to form the idea, on evidence that we couldn't see with our own eyes.

Q. Are you acquainted with any literature bearing upon the subject of malaria in St. Louis?

11506 A. Yes, I have tried to read all I can find. There isn't much, the doctors there have not written much on it, but I have read some of them.

MR. JEFFRIES I object to the witness stating he has read the literature unless he states what it is.

MR. TODD: Q. Will you state what you have read on the subject?

A. Well, I have read a number of articles in the local journals. It would be hardly necessary for me to mention the articles, but I might mention an article by Dr. Bremer, a well known physician of St. Louis.

MR. JEFFRIES: I object to the witness stating anything the doctor has said in the magazine article for the reason it is incompetent, and I object to the production of the magazine for the reason it is no evidence that it is the opinion of Dr. Bremer, and that it is incompetent evidence.

MR. TODD: Q. Have you got that article with you?

A. Yes sir, I have.

Q. Will you produce it?

11507 A. Yes. I have here a medical journal known as the Medical Review, a weekly journal of medicine and surgery published in St. Louis and the number I have is the number for August, '95. In this article Dr. Bremer states as follows:

"In our part of the country and probably throughout the larger part of the United States, physicians are apt even today to look upon many ailments as due to malaria, which in reality have nothing to do with this disease either directly or indirectly." There is a foot note, which is as follows:

"This means St. Louis and environments in particular, and the Mississippi valley in general, but it probably applies to the whole United States."

In another place he states as follows:

"Peoriodic chills, followed by high temperatures, which mark the initital stages of so many cases, are generally interpreted as due to malaria, hence the erroneous and mischievious diagnosis, malaria, remittent fever, or typho-malaria, under which names so many cases of typhoid figure in the reports of our city Boards of Health."

11508 Also the following: "Now, a practical question, to what extent does malaria exist in our part of the country (The Mississippi valley) and particularly in St. Louis, basing my opinion on the examination of about five hundred individual cases of all sorts of individuals, many of whom were examined over and over again within the last seven or eight years, I have come to the conclusion that in our city at least, malaria is an extremely rare disease, so rare indeed is this disease, at least in its pronounced forms, that when about four years ago I went to the City Hospital for a number of months in the hope of finding a good, plasmodium infected subject, my efforts were unsuccessful for a long time. The cases pointed out to me by attending physicians as malaria and treated as such, proved to be infections which had nothing in common with that disease."

MR. JEFFRIES: I move to strike out the matter which the witness has just read into the evidence, as being an article purporting to be written by Dr. Bremer, of the City of St. Louis, for the reason that there is no evidence showing that this Dr. Bremer is not within the legal jurisdiction of the Com-
11509 missioner, and therefore there is no reason why he should
not be called upon the subject matter, so that the complainant might have an opportunity to cross-examine.

MR. TODD: In reply to the objection will state, that the same rule applying to the admissibility of this class of testimony, if made to apply to the same class of testimony offered by the complainant, in nearly every witness, with few exceptions, as having testified on complainant's side of the case, is invoked, I have no objections.

A. I might say that this bears out the experience I have had myself in various places, having the general climatic conditions of St. Louis in mind, and especially with the experience I had in 1898, in some of the army camps. I was asked by the Surgeon General—

Q. State what experience you had in the army camps to which you referred, in detail?

A. I was asked by Surgeon General Sternberg, of the United States Army, at that time, to visit certain army camps in order to examine the blood of patients diagnosed largely as malaria. In accordance with that, I examined the Sternberg general hospital at Chickamauga, the hospital at Knox-
11510 ville, and at Camp Meade, Pennsylvania. At that time
most of the cases of typhoid in the army camps were

diagnosed malaria. In the Sternberg hospital, for example, there were 400 patients when I got there, and practically all of them had a diagnosis of malaria, in one form or another, typho-malaria, bilious remittent, or some such name. I examined most of these patients individually. I examined their blood and examined their clinical features with the result that I found only one case out of the whole 400 had malarial fever.

I also made some autopsies on patients dying with so-called malarial fever, and found that they had typhoid fever, without malarial.

Then I went to Camp Meade, Pennsylvania, where the conditions were practically the same. When I got there 80 per cent of all the fever cases had a diagnosis on their bedsides of malarial fever with various modifications of the malarial part. Within a few days those diagnoses were changed just around, 80 per cent typhoid, and 20 per cent malaria. I examined all the suspected malaria patients, many of those who had been suspected as having malaria, and there, too, I found only one patient out of several hundred that really had mala-
11511 rial fever. The disease was in practically all the cases typhoid.

At Knoxville, I was not able to find any malarial cases.

I reported this matter to the surgeon general, but my report has not yet been made public.

Q. What other experience have you had, outside of the army camp, and what you have already given, in regard to the question of malaria and typhoid?

A. Well, such experience as a doctor has treating patients in general hospital work, where people are likely to be sent in with local diagnoses, and even in Michigan, I still see physicians who are giving wrong diagnoses for typhoid fever.

Q. Have you made a special study of typhoid fever?

A. Yes sir.

Q. How extensive have been your studies upon the subject of typhoid fever?

A. Well, I have been studying it persistently for about 20 years. I have made several hundred autopsies on patients who died from typhoid fever, not all of them my own patients,

however—and on a great many patients diagnosed as
11512 either having typhoid fever or having some other disease. In such cases, the diagnoses were often wrong. For example, that of typhoid fever would be mistaken for some other disease or some other disease would be mistaken for typhoid fever. From such experiences I think I have seen a good deal of typhoid fever.

Q. Have you made a special study of the so-called germ diseases?

A. Yes sir.

Q. Do those diseases caused by germs come within the scope of your studies?

A. Yes, very intimately.

Q. Have you made any study upon typhoid fever and malarial fever from the standpoint of a bacteriologist, or clinician?

A. Yes sir.

Q. In connection with such study as you have detailed, have you taken up the question of the proper diagnosis of fevers of the kind known as typhoid and malarial?

A. Yes, very particularly.

11513 Q. Have you had any experience in the diagnosis of these fevers either in the laboratory or at the bedside?

A. Yes, very extensive.

Q. What is typhoid fever in its clinical diagnosis?

A. Typhoid fever is an infectious disease caused by the germ known as the typhoid bacillus, characterized by certain swellings in the lymphatic glands, especially in the alimentary canal, and the mesentery glands, and the spleen, and sometimes in the other organs, like the kidneys, the lungs, and the nervous system, and also in the blood, characterized clinically by fever, by certain eruptions, by enlargement of the spleen, and a tendency to diarrhoea, a tendency to the swelling of the abdomen, to a certain change in the nervous system associated with delirium, and varying very much, so that, in its automical and clinical features, in many cases there may be very little fever, and in some cases all common symptoms are absent, and the ordinary clinical picture of typhoid may not be seen. Among

the most important tests of the disease is the so-called Widal reaction, which consists in a change produced on the ty-
11514 phoid bacilli, by subjecting them to the action of the blood of a patient with typhoid fever, and another very important test is the finding of the typhoid bacilli in the blood.

Q. What is intermittent fever and its clinical diagonsis?

A. Intermittent fever is a name formerly used largely as a synonym for malarial intermittent fever and the name is still used by many people for a common form of malarial fever, but it is a very unsatisfactory name because there are a great many diseases that have intermittent fever. This is a fever that at certain intervals disappears leaving the temperature about normal.

Q. What is remittent fever and its clinical diagnosis?

A. Remittent fever is another unsatisfactory term. Some malarial fevers are remittent, but a great many other fevers are remittent. Diseases like typhoid fever, tuberculosis, various kinds of blood poisoning, frequently have remittent fever. This is a fever in which the temperature does not reach normal, but that has remissions, that are more marked than those that occur normally. That is to say more than about two
11515 degrees Fahrenheit a day.

Q. What is typho-malarial fever and its clinical diagnosis?

A. Typho-malarial fever is a name that is no longer used by any careful clinician or pathologist or bacteriologist, because it has been so loosely applied. There is no definite disease now known as typho-malarial fever. The name, as we find it in practice, usually is applied to typhoid fever.

MR. JEFFRIES: Q. Mild cases?

A. Not always mild, some of them severe. But the word is also used very largely as a cover for diagnostic difficulties. Various diseases that are not more accurately diagnosed have the name of typho-malarial given to them.

MR. TODD: Q. What is congestive fever and its clinical diagnosis?

A. There is no definite disease known as congestive fever. Any fever that can be recognized by the thermometer is some-

times spoken of as congestive fever. It does not mean any definite disease at all. It is merely a symptom, but the
11516 name is given to various diseases.

Q. What is simple continued fever and its clinical diagnosis?

A. Simple continued fever is a name given to various diseases, and the name as given has not been more accurately diagnosed. It is applied in cases of mild fever. All sorts of fevers that doctors cannot trace down to any more definite cause.

Q. Are remittent, intermittent, typho-malarial, congestive and simple continued fevers distinct types of disease and so recognized by bacteriologists and clinicians?

A. No sir. Usually all such names are included by careful boards of health under the heading of typhoid fever.

Q. What significance do you attach to these terms as applied to fevers when they appear in vital statistics of health reports?

A. As I have just said, they usually refer to typhoid fever. My own experience with them among doctors and in the hospitals and in the post mortem room is that they are applied to typhoid fever in the majority of cases.

11517 Q. Do the sypmtoms of typhoid fever closely simulate the symptoms characterized under these headings?

A. Sometimes rather closely, yes. Especially if one is not particularly educated on the finer diagnostic points. An examination of the blood of the malarial organs, on one hand, or the typhoid reaction on the other, usually clears them up very quickly, but, to a casual glance, the diseases may be very much alike.

Q. Assume that the number of deaths reported as occurring from typhoid fever in the city of St. Louis as evidenced by the annual report of the Board of Health of the city of St. Louis Health department is as follows:

1890	140
1891	165
1892	441
1893	215
1894	171
1895	107
1896	106

	1897	125
	1898	95
	1899	131
11518	1900	168
	1901	198
	1902	222
	1903	288

And assuming for the sake of the question that the number of deaths for the respective years correctly represent the typhoid condition in the city of St. Louis, what is your opinion based upon the statistics as assumed in the foregoing question as to whether there has been an increase in typhoid fever in the city of St. Louis during the last ten years?

MR. JEFFRIES: I object to the question for the reasons that the conditions existing prior to '95, are different from the conditions subsequent thereto and subsequent to the opening of the Drainage Canal and therefore the typhoid statistics for the city of St. Louis, for a date prior to '95, on account of the change in the waterworks of that city are not comparable with the typhoid data of a subsequent date or period.

A. The figures show an increase.

(Question repeated.)

A. I should say there has been an increase, but not a great increase.

11519 MR. TODD: Q. How is it manifested from the statistics and give the reasons for your answer?

A. Well, the increase, say, for the last five years, or even six years from 1895 to 1903, is a steady and gradual increase. There is no one point, there, where one can see a sudden increase out of proportion to the general line. I am particularly struck by this increase since 1898 because in 1898 the doctors all over the country had their attention very strongly called to the wrong diagnoses that were formerly made in the so-called typhoid diseases, and the attention of the public has been very strongly called to it.

Q. In what way?

A. As shown in the army camps, especially. That there soldiers were dying of typhoid, that were supposed to have malaria. The people found out it was possible to make a more

accurate diagnosis, and doctors in my experience in various parts of the country have been more careful in their diagnoses since '98. They have been using more accurate means of diagnosis, such as the microscope, and the bacteriological test, so that, while I see an increase I wouldn't call it a great
11520 or a sudden increase.

Q. Assuming the statistics in the foregoing question as above indicated and assuming further that the number of deaths reported in the same reports under the headings remittent, intermittent, typho-malarial, congestive and simple continued fevers, is as follows:

1890	226
1891	296
1892	326
1893	284
1894	179
1895	155
1896	177
1897	172
1898	134
1899	148
1900	112
1901	80
1902	102
1903	91

Do the number of deaths reported occurring from typhoid fever alone in the city of St. Louis properly represent in
11521 your opinion the total number of deaths actually occurring in that city in the period in question?

A. No.

Q. What reasons have you for stating that they do not?

A. The most important reason is that the death rate from malarial diseases is altogether too high, too high for every year. Take an exceptional year for typhoid, when there was an accidental condition, the malaria there is 50 per cent higher than it was two years before. In 1890 there were 226 cases of the malarial disease. I include all these various diseases in malaria. In 1892 there were 326. Now, from studying malaria very carefully at that time, I say there was no reason why malaria should increase in a city like St. Louis to that extent at that time. The death rate in every year is altogether too high in a city like St. Louis. It is higher than I believe possible.

Q. What is malarial fever?

A. Malarial fever is a disease caused by certain animal parasites that live in the blood, and, that are characterized clinically by different kinds of symptoms. In the first place, 11522 cases with intermittent fever, a fever that varies from normal, or about normal, to several degrees above, every day or every other day, or every third day, sometimes by remittent fevers, where the temperature does not reach normal, but varies more than about two degrees Fahrenheit, every day, and sometimes by rather irregular fevers, and sometimes causes a condition known as malarial cachexia, where the patient is weak, anaemic, and has various symptoms that might not strike one as being due to malarial disease originally.

Q. Are there different, distinct types of malarial fever?

A. Yes sir.

Q. What are they?

A. In the first place there is the tertian type in which the patient has a paroxysm every other day, and the quartan type, with a paroxysm every third day or at intervals of 72 hours, and then there may be combinations of these types so that the patient may have the fever every day and may even have more than one paroxysm in a day, or other combinations of the various paroxysms. Then, there are remittent fevers that 11523 are caused by a different kind of parasite in which the fever may go as high as it is in the intermittent fever and even higher, but the temperature does not fall to normal during the course of the disease. These are the more dangerous kinds of malarial fever. They are often spoken of as tropical fevers because they are especially common in the tropics. And these are the chief types. All other types are combinations, or varieties of these.

Q. Are those types found in this country?

A. Yes.

Q. To any extent?

A. No, not above the latitude of Arkansas. They may occur sporadically as far north as Baltimore, or Philadelphia or Chicago. In such cases they occur very sparingly, so sparingly that even a very experienced malarial student may not see a case of this kind.

Q. What is the type of malaria that is common in the central states of the Mississippi Valley?

A. The intermittent form.

Q. Have you had any experience with that type of malarial fever?

11524 A. Yes sir.

Q. Is that type of malarial fever considered a fatal type of fever?

A. Practically never. Nobody ever dies of it unless he has had some previously exhausting disease.

Q. To what do you attribute the failure of these statistics assumed in the foregoing hypothetical questions, to properly disclose the number of typhoid fever deaths occurring in the city of St. Louis?

A. To the use of the term "malarial fever, typho-malarial fever," etc., applied to certain cases of typhoid fever.

Q. Why is it that the doctors employ the terms remittent, intermittent, typho-malarial, congestive and simple continued fevers to fevers that are recognized as being either typhoid or malarial, or some other disease?

A. There are different reasons. In the first place, very often the doctor has an incomplete idea of the diagnosis of typhoid fever. That is, his idea of typhoid fever is not correct. Then, he does not use the methods of diagnosis necessary. Very often, possibly, it is done for what might be termed business reasons or social reasons, a doctor does not like to give out the impression that his town has a lot of typhoid fever
11525 in it. Or, he may even have an intimation from the
health authorities not to give it out. In the army camps, surgeons were frequently ordered by superior officers not to make out a diagnosis of typhoid fever. All these reasons apply in various towns to different degrees, health reports, for example, the diagnosis of typhoid fever is always very unpopular. They

fall back on some other word, especially tpho-malarial. Cities that are going to have World's Fairs in them always object to having such a name used. In places where people might be frightened by the diagnosis of typhoid, there is an instinctive feeling on the part of doctors that they ought to use some other word.

Q. Do you know of any city in the country where the death rate from malarial fever alone is as high as in the city of St. Louis, as evidenced by the number of deaths as assumed in the hypothetical questions under the heading intermittent, remittent, typho-malarial, congestive and simple continued fevers occurring in the reports of the Board of Health of the city of St. Louis?

A. Well, the only city that I could find that gives out such a rate is New Orleans, where, in the first place, the
11526 probability of getting malaria is much better than in St. Louis, and where also the typhoid diagnosis is very often wrong.

Q. Have you any particular knowledge upon the condition at New Orleans in regard to typhoid?

A. Well, I have taken pains, and especially when living in the South, to find out about the conditions there. I made no examinations myself, there.

Q. What proportionate deaths in the column under the heading remittent, intermittent, typho-malarial, congestive and simple continued fevers, assumed in the foregoing hypothetical questions as occurring in the city of St. Louis as evidenced by the Board of Health, in your opinion should be classed as typhoid?

MR. JEFFRIES: Object to the question for the reason that any answer the witness may give would be speculative, not knowing more of the conditions at St. Louis than the witness has testified to, and therefore any opinion he might express would be uncertain and unreliable.

A. From the statistics that have been furnished, and from my experience in the diagnoses of typhoid fever, and typho-malarial fever, I should say it would be impossible to say exactly how many cases, but anywhere between 50 and 90

11527 per cent of the so-called malaria ought to be called typhoid. At least 50 and probably as many as 90.

MR. TODD: Q. What proportion as malarial fever?

A. That would be speculation, too, but probably not more than 2 or 3 per cent. For a city like St. Louis a death rate of 2 or 3 per cent from malarial fever would be very high.

Q. What do the mortality statistics of malaria show in cities where careful attention has been paid to malarial fevers as regards the number of deaths occurring from malarial fever?

A. Well, there are no cities in this country that have actual statistics on that point. The best places to get statistics are in hospitals, where they pay special attention to malaria, and an experience of a hospital like the Johns Hopkins Hospital, where they have climatic conditions, rather more favorable for malaria than those of St. Louis, might be taken. In ten years, they were able to get only three deaths from malarial fever. That is practically nothing at all in comparison to what St. Louis has in one year.

Q. Is it generally recognized by bacteriologists, clinicians and pathologists that classifying typhoid fever in one
11528 column, and intermittent, remittent, typho-malarial, congestive and simple continued fever in another column, in board of health reports of cities, is an improper classification from a scientific standpoint as affording a true indication of the mortality from typhoid fever and malaria?

A. It is generally recognized, and most careful boards of health refuse to accept such classification, because all such diseases should be put in the typhoid table.

Q. Have you in mind any board of health?

A. The board of health of Michigan, for instance, orders that all typho-malaria be classified under typhoid, and the new classification recommended by the United States census makes that same recommendation.

Q. Assuming that the reports of the board of health of the city of St. Louis, by the month, from 1895 to 1903 inclusive, under the heading, typhoid fever, which for the purpose of convenience, is designated A, in the table as follows, and as intermittent, remittent, typho-malarial, congestive and simple continued fevers for the sake of convenience is designated as B, in the table of columns, which table was prepared and sworn to by Prof. Jordan, is based upon said reports, and is as follows:

11529 ST. LOUIS.

	1895		1896		1897		1898		1899	
	A.	B.	A.	B.	A.	B.	A.	B.	A.	B.
Jan.	12	10	4	13	7	7	4	6	10	4

May	4	7	8	7	11	8	15	8
June	8	12	6	9	7	4	18	8
July	15	9	13	15	14	12	27	10
Aug.	20	20	31	5	26	7	37	10
Sept.	13	20	24	9	21	16	42	17
Oct.	30	9	32	11	32	17	29	17
Nov.	15	3	27	5	31	9	24	3
Dec.	19	7	20	3	25	6	31	5

A—Typhoid fever.

B—Remittent, intermittent, typho-malarial, congestive and simple continued fever.

11531 Will you please state what construction you place upon this table, as showing the relative mortality from typhoid fever and malarial fever in the city of St. Louis during the periods covered by the foregoing table?

A. The chief conclusion I draw is, to conform to what I said before, as to statistics regarding malarial diseases, that they are not altogether faulty. It comes out more clearly when one studies the reports of malarial diseases by months, where the death rate is altogether impossible for malaria, in the latitude of St. Louis. For example, the typhoid deaths reported for the months including January, February, March and April, nobody dies of malarial fever in that latitude in those months. Severe malarial disease cannot occur then. It might occasionally happen that a man would die of Bright's disease who had malaria years before, and his death might be reported as from malaria, but that would not be such a case as we are speaking of now. Even in such a malarial country as the Philippines, malaria does not kill all the year round. In several months, the months corresponding to our winter season, they do not have any deaths from malarial fever.
11532 A study of this table would be enough to show that the whole malarial statistics of that town are seriously faulty.

Q. Assume that the added totals of tables from typhoid fever and the tables from remittent, intermittent, typho-malarial, congestive and simple continued fevers as they appear in the reports of the Board of Health of the city of St. Louis, is as follows:

1890	361
1891	381
1892	767
1893	499
1894	350
1895	262
1896	283
1897	297
1898	229
1899	279

1900	280
1901	278
1902	324
1903	379

11533 What do these totals as above indicated represent in your opinion, as the mortality condition of the typhoid fever in the city of St. Louis, covering the period as above indicated, after allowing the said remittent, intermittent, typho-malarial, congestive and simple continued fever column such proportion as being typhoid fever as in your opinion you should allow, what is your opinion as based upon the statistics as assumed in the foregoing hypothetical question as to the typhoid deaths under the remittent, intermittent, typho-malarial, congestive and simple continued fevers, tables, in the city of St. Louis, as to whether the said statistics show an increase or decrease in the typhoid fever mortality in the city of St. Louis, since 1899, eliminating the year 1892, which was the year of a special epidemic?

A. They do not indicate a marked increase, though they indicate a slight and gradual increase from the year '98. An increase that I would explain partly from the fact that the diagnosis of typhoid fever has become broader, all over the country. More cases are being included. There is a tendency everywhere to increase the proportion of typhoid cases in that way. There has been a slight and gradual
11534 increase.

Q. Is the increase as marked under this interpretation of the statistics as it is taking the typhoid fever column as heretofore assumed as the measure of typhoid conditions in St. Louis?

A. It is not as great, no.

Q. Is there anything in the statistics as they appear, to show any explosion of typhoid fever, as due to any particular cause manifested in these statistics?

A. Not at all. The increase for example is slightly more marked for the year 1901, but even there it is not at all striking. It is not such a thing as we find, for example, in the case of Butler, Pennsylvania, or in the case of Cornell College, in the town of Ithaca.

Q. Assume that two circular letters, one issued in the fall of 1900 and another issued in the fall of 1901, were issued by the Health Commissioner of St. Louis, calling the attention of physicians to the fact that the law requires them to report all cases of typhoid and all deaths from typhoid and at the time that the letters were sent out, the question of opening the Drainage Canal was being agitated in the public press of the city of St. 11535 Louis, and there was considerable discussion and an investigation was going on at that time of the analysis of the samples of water collected, etc., and was attracting considerable attention. From your examination of the statistics of St. Louis as heretofore assumed in the hypothetical question heretofore asked you for the years 1900, 1901, and 1902, as compared with previous years, does the effect of such a letter, assuming that the same had been sent out to the doctors by the Health Department of St. Louis, manifest itself in those statistics?

A. I think the sending out of such a letter would explain the rise that has occurred in the last five years. Of course we have to stick to the last two years, on account of the letter, but the increase is not so great as one might expect. Such an order or such a letter, calling attention of physicians to the fact that the law required them to report all cases of typhoid, has been carried out in many other cities, and the increase has always been marked, I mean, has been distinct. Here there is an increase, too, but it does not strike me as being very much greater than it was in the three years before.

Q. These are deaths, not cases.

11536 A. I should say deaths.

Q. How does it manifest itself in the typho-malarial column?

A. That goes down, as one might expect. Doctors having their attention called by the notification would report more cases as typhoid, and less as typho-malarial. than they had before.

Q. From your examination of the typhoid and typho-malarial group of deaths as assumed in the foregoing hypothetical questions, what is your opinion as to whether these two tables taken separately, correctly show the typhoid conditions in the city of St. Louis for the period mentioned?

A. My opinion is that the two tables taken separately do not correctly show the typhoid condition.

Q. Upon what do you base your opinion that they do not correctly show the typhoid conditions of the city of St. Louis, taking them separately?

A. For the reasons I think I have mentioned before, that the diagnoses of malarial diseases were almost entirely erroneous and should have appeared largely under the head
11537 of typhoid.

Q. From your knowledge of these classes of fevers mentioned in the two columns of vital statistics as heretofore assumed, how should they be treated by clinicians and statisticians and pathologists in order to arrive at the true typhoid fever mortality in the city of St. Louis?

A. The safest way would be to look upon all these anomolous fevers as typhoid. It would not be accurate to say—one could not use them accurately because there is not enough evidence to make an accurate conclusion.

Q. Assuming that the following table testified to in evidence by Prof. Jordan, as compiled from the typhoid fever mortality, and typho-malarial, etc., mortality of the health reports of the city of St. Louis and based upon the mortality of the city of St. Louis for the years 1890 and 1900 according to the United States census reports and the intervening years estimated by Farr's formula, which table is as follows:

11538

TYPHOID FEVER DEATH RATES.
ST. LOUIS.

Year.	Population.	Death rate per 100,000 of typhoid fever alone.	Typhoid fever plus 50 per ct. of deaths recorded under heading intermittent fever, etc.	Typhoid fever plus all the deaths recorded under the heading intermittent fever, etc.
1890	451,709	30.0	56.67	81.2
1891	462,763	35.6	58.98	82.3
1892	474,077	93.0	127.40	161.7
1893	485,668	44.2	73.52	102.7
1894	497,565	34.3	52.24	70.3
1895	509,740	29.9	30.35	51.3
1896	522,225	20.2	37.37	54.1
1897	533,762	23.4	39.53	55.6
1898	548,590	17.3	29.53	41.7
1899	361,510	23.3	36.49	49.6
1900	575,238	29.2	39.07	48.6
1901	589,315	33.5	40.39	47.1
1902	603,736	36.7	45.21	53.6
1903	618,510	46.5	54.0	61.3

11539 Will you please state what is your opinion based upon the tables heretofore read, as to whether typhoid fever has increased or decreased in the city of St. Louis since 1900 over the conditions that obtained in St. Louis prior to 1900?

MR. JEFFRIES: I object to the question for the reason that it does not restrict the answer to periods subsequent and prior to January 7, 1900, and they are not comparable with each other.

A. The table does not show that there has been a marked increase; on the contrary, a slight increase. Such an increase as I would ascribe rather to increased care in diagnosis, rather than to any outside conditions.

MR. TODD: Q. What effect would local conditions have upon an increase such as you have defined it to be?

A. The figures are compatible with such slight increase, as we find here, and typhoid fever, in most places, like most other diseases, runs cyclicly, without any fresh conditions from

the outside, or any marked condition in the matter of water supply or drainage. I should think in the last two years there would have been conditions in St. Louis which would
11540 have increased the typhoid incidents. The fact that
many people were going there, people not accustomed to the climate, perhaps living carelessly. In nearly all such times we see such epidemics breaking out.

Q. What effect do wells in a city have upon the typhoid conditions?

A. One of the most serious sources of typhoid fever where they have surface drainage and wells both, the conditions are especially dangerous. In cities that have a good water supply, but still have wells, they always have a distinct amount of typhoid fever. The wells in small cities and in rural districts are very serious causes of typhoid fever.

Q. Assuming that on April 1, 1895, the total number of wells in the city of St. Louis was 4,846, and assuming that pursuant to an order of the Board of Health of St. Louis, directing an examination of these wells, that the city chemist, after examining 59 wells, condemned them as being unsanitary, and, assume further that in August, '95, upon the report of the city chemist condemning seven more of these wells, the Board of Health of the city of St. Louis, passed a resolution that
11541 the city should make no further examination of the wells
in question, and since August, 1895, none of these wells has been condemned, what effect would this number of wells in the city of St. Louis have in your opinion upon the typhoid conditions existing in the said city, assuming that the water of these wells was used by the inhabitants for drinking and domestic purposes.

A. It would be a very serious source of typhoid fever.

Q. From a consideration of the statistics that have been assumed in the foregoing hypothetical question, and the condition of typhoid fever in the city of St. Louis, for the period referred to, what in your opinion is the cause of such slight increase in typhoid fever in St. Louis, as you have stated? Give in full your reasons for your opinion?

A y opinion is that the increase indicates rather a change in the conditions of the city of St. Louis itself rather than in the main water supply, supposing that the main water supply comes from a river.

A change in the condition of the river water is always indicated in such cases by a more marked increase. As to such an increase as we have here, it is altogether compatible with changing local conditions, such as wells, and the ordinary
11542 course of typhoid epidemics.

ADJOURNED until 2 p. m., same day, March 12, 1904.

11543 2:00 o'clock p. m., March 12, 1904. Continuation pursuant to adjournment.

Present, the Commissioner, and the same counsel representing the respective parties.

PROF. GEORGE DOCK

resumed the stand for cross-examination by Mr. Jeffries, and testified as follows:

Q. Are you now engaged in the active practice of medicine?

A. Yes sir.

Q. What school of medicine do you belong to?

A. The regular school.

Q. Do you know what school Dr. Bremer belongs to?

A. No. I imagine he belongs to the regular school, too.

Q. Don't you know it to be a fact that he is a specialist, and not engaged in fever practice of any kind?

A. Well, along about that time he was very actively engaged in the examination of the blood, made quite a reputation for himself, as a blood expert.

Q. His practice, though, was not extended to typhoid
11544 and other fevers at that time, and has not been since that time?

A. Well, I don't know what his practice has been since then. While his practice might not include those diseases, I see no reason why he should not be credited with having worked on the subject.

Q. Did you ever practice medicine in St. Louis?

A. No sir, I never did.

Q. What was the extent of your examination in typhoid fever mortality in St. Louis, that you made?

A. Well, the only investigations of the mortality have been those of the figures submitted to me.

Q. What was the character of your examination, with reference to the particular disease known as malarial fever, at St. Louis?

A. This included a study of the reports that have been published by the doctors, and the literature. I had to read up on the literature of malarial diseases, and tried to read what the doctors there had published about malarial conditions.

Q. Did you examine malarial fever patients while there?

11545 A. No sir.

Q. Made no examination except what you found from the reports?

A. I examined some written descriptions at one time, sent me by a doctor who was investigating malaria, there, a doctor who is now dead, Dr. Blickhahn. Blickhahn began writing me on account of having seen some of my papers on malaria. I gave him a good deal of assistance in working up the subject. He used to send me his preparations, to see whether he had the right thing or not, and he wrote me at one time, after he had been working at the thing about two years, that he had never been able to see a certain form of malarial organism, that is, the so-called crescent. I was rather surprised at that, because I would have rather supposed, I would have thought that he would find crescents in St. Louis. Crescents are found in the more severe form of malarial fever. The severe types have these bodies associated with them. Blickhanhn wrote me that he had not been able to find them and asked me to send him one of my specimens. I sent him some specimens that I had brought from Texas. I supposed he had simply overlooked them, 11546 but he wrote back and said he had really not seem them, up to that time. That was additional evidence that severe forms did not occur frequently there, although of course they might occur now and then. I have paid little more attention to the conditions in St. Louis, than I have a good many other towns.

Q. When was that?

A. That was during 1903 and 1904.

Q. You never visited St. Louis, for the purpose of making any special determination?

A. No sir.

Q. You only speak of such observations as you had while passing through, or in discussing the matter with other physicians?

A. And reading the articles.

Q. What diseases, Doctor, are fatally allied, of a fatal character with typhoid fever?

A. I do not think I understand your question.

Q. Well, are there any diseases?

A. I don't think I understand your question, in reference to the word, "allied."

11547 Q. What fevers known as fevers which would produce death, may in a sense be associated with typhoid fevers?

A. Well, in this country there are practically none, especially in the northern latitudes.

Q. You mean, then, in this latitude, that every death that is attributed to fever, is from typhoid fever?

A. No, not that. I mean to say that any disease that sets up any very great infection, in a large number of cases, is typhoid. There are in some other countries, such fevers, typhus fever, for example, even that, at the present time, that we cannot distinguish quite positively from typhoid.

Q. How does typhus fever differ from typhoid fever?

A. Well, the chief point in their diagnosis is that it does not give a Widal reaction. You do not get the typhoid germs out of the blood. They are very difficult to distinguish without those tests.

Q. Is that disease common in this country?

A. Typhus?

Q. Yes?

A. Very rarely. They are only brought in at long intervals.

Q. From what country?

11548 A. Particularly from Russia, nowadays. Sometimes from Ireland, and sometimes possibly from Mexico.

Q. Is there anything in the natural conditions of this country that would prevent its spread or distribution in this country over those of countries where it is known to be prevalent?

A. Yes sir, very distinctly. Typhus fever is a disease of extremely bad sanitation and poor feeding. It can hardly exist without those conditions.

Q. And in that respect it differs from typhoid?

A. Yes. Of course that is not a clinical difference, though.

Q. What cities have you examined the mortality record of, with reference to making a distinction between the various fevers, and typhoid fever?

A. Well, I have examined such places as New Orleans, Baltimore, Washington, New York, and Philadelphia.

Q. How do those cities compare with St. Louis?

A. I cannot give you a definite answer, because my information of the mortality reports was not very great. I would not look on it as being very useful evidence. I found, 11549 however, in Baltimore, just about the same climatic conditions, if anything a little bit worse than in St. Louis. I found that their reports of deaths from malaria were lower, proportionately to the population than they were in St. Louis. In Washington they were about the same, but the statistics in Washington have been shown by some doctors, some of the leading doctors there, to be extremely faulty, and in that respect they have shown that practically all the cases represented as dying from malaria, were cases of typhoid.

Q. From your examination of the mortality records of St. Louis, you have arrived at the conclusion that physicians of that city are not competent to make the determination as to the character of the disease?

A. I would not say that all the physicians, but I have already put myself on record as saying that a large number of the physicians are not making correct diagnosis in these diseases, and I have no hesitation in repeating it here.

Q. And you have expressed that opinion altogether from the record?

A. Partly from the record and partly from the facts bear- 11550 ing upon the occurrence of this disease, and partly from my experience in certain definite places where I have investigated the actual cases, and partly by becoming familiar with a good many doctors, from all over the country. In the army camps, for example, I saw doctors from every state, and saw how they made their diagnosis, and I was able to see that a large majority of them were making faulty ones, and I was able to demonstrate that they were.

Q. And in that way you observed that these physicians had been instructed by the government to report the disease as something else than typhoid fever?

A. Not by the government, no.

Q. Where did these instructions come from?

A. They were not wide-spread, or general instructions. And they were not medical officers, but military officers.

Q. Will you name some of them?

A. Well, I do not believe I could recall their names, now.

Q. At what place?

A. At Chickamauga.

Q. What time?

A. In September, '98.

11551 Q. Who was in charge?

A. At the time I was there, Dr. Giffin was in charge of the hospital. He, however, was not a military officer. General Brooks had been in charge and left soon after I got there.

Q. You don't know whether Gen. Brooks gave that order or not?

A. I don't believe Gen. Brooks did.

Q. Do you believe that his successor did?

A. No, I think it was some inferior officer.

Q. Well, if you cannot name the officer who gave the instruction, or the order, how did you know that the order was made?

A. I had a statement from persons that I thought were reliable, and in such repeated form, and so pointedly expressed, I had no doubt about it, at all.

Q. Tell some of those persons that gave you that information?

A. Well, I have not any record of their names. I could not give you the names, now.

Q. Have you the means of ascertaining their names?

A. I could ascertain some of them, if I had access to the record. One of them is a surgeon now, for the United States army. I can give you his name, Dr. Charles F. Craig.

11552 Q. Did he tell you where he got his information, or orders?

A. I do not think he got orders; he got information, I think he mentioned the names at the time, but of course I wasn't interested in remembering those things. My duties were simply to diagnose the cases.

Q. Then it is from what you obtained from those army officers who were not in superior power, that you speak of, that you believed that such orders had gone out, did you?

A. I did, yes sir. I did not understand, however, those were formal orders that were given over every large command, but I believe that such orders were given, and influenced certain doctors in making certain reports.

Q. After obtaining this information, did you call upon those doctors and see whether or not there was any truth in the statement?

A. No, but I examined their patients.

Q. But you said nothing to them, at all?

A. Well, I was too busy to discuss the matter with them.

Q. What were your duties?

A. I was examining the patients.

11553 Q. Who for?

A. For the Government.

Q. Did you say anything to the government about these instructions that had gone out?

A. No.

Q. That orders had been given to withhold typhoid statistics?

A. No, I simply reported my results.

Q. You made no report upon that proposition at all, as to what you had heard?

A. That was not a part of my duty.

Q. What you heard reported among the army officials, that was not a part of your duties?

A. That was not a part of my duty at all.

Q. On the contrary, it was your duty to keep still, was it?

A. No sir, I had nothing to do with the case at all. I was there to examine certain patients and I did that.

Q. What patients were you there to examine?

A. Any patient that might be said to have malarial fever.

Q. At that time?

A. At that time, yes sir.

Q. How many patients did you examine, there, in round numbers?

A. Four hundred. And there were really more than four hundred, but actually about four hundred patients in the
11554 beds at one time.

Q. All of whom had typhoid fever?

A. Not all of whom, but most of whom.

Q. Now, is there any other instance in your experience where such orders have been given, by army authority?

A. I do not recall any similar statements in the other camps.

Q. Do you know of any such authority having been given?

A. No.

Q. That is the only instance you have in mind at Chickamauga?

A. Yes sir. But I would not say that is an isolated instance, because there were a large number of separate, small camps.

Q. But I mean the instance of Chickamauga, and the conditions that existed there with reference to this particular character, or order, is the only camp, army camp, that was subjected to an order of that character?

A. That is the only one where I have a distinct recollection of such a thing having been talked about.

Q. Upon the tables which were read to you, this morning, and which tables were introduced in evidence by Prof. Jordan, I will ask you if a comparison of the strict report of ty-
11555 phoid fever cases, based upon the number of deaths, per 100,000 population, for the year '96, 22.22; '97, 23.4; '98, 17.3; '99, 23.3; 1900, 29.2; 1901, 33.5; 1902, 36.7; 1903, 46.5, making an average for the four years immediately prior to the opening of the canal, of 22.8 per 100,000 and the four years immediately following the opening of the canal, 36.5 per 100,000,

I will ask you if that does not show, based upon the tables reported, an increase of about 74 per cent?

A. You ask me whether the tables show?

Q. Yes?

A. Well, I could only tell by calculating it, and I am not here as a calculating expert.

Q. From the face of the tables, themselves, can you make any estimate of the approximate increase?

A. I could if I calculated it, but I say it shows an increase on the face of the figures.

Q. Doesn't it show a very large increase?

A. It shows a considerable increase, yes sir, I would not call it a very large one.

Q. Taking one-half of column B, or one-half of the intermittent, remittent, typho-malarial, congestive and simple 11556 continued fevers, for those years mentioned in the last preceding question, I will ask you if it does not show a very decided increase?

A. No, I don't think it shows as much of an increase as the first column, for typhoid, alone.

Q. No, but it shows a decided increase?

A. It shows an increase, yes sir.

Q. Going back to the straight typhoid, as reported, I will ask you if 74 per cent increase would not be considered by you as a great increase?

A. It would be a great increase for the town, for the people who were sick, but it would not indicate necessarily a radical difference in the question of infection.

Q. That based upon the population, of cases per 100,000, would not an increase of 74 per cent be considered by you as a physician, a great increase?

A. No.

Q. It would be an increase, then of no material difference, and of very little consideration?

A. I say it would be a very important difference to the people who were sick, and for the town, but it would not 11557 mean that there was a very radical change in the mode of infection. Where a change takes place in the method of infection in a town that always has typhoid, the change is much greater than the fraction of 100, it is several hundred per cent, or at least more than 100 per cent, that is what I mean.

Q. You mean, in cases of epidemics?

A. In the case of an epidemic. For example, the difference of 70 odd per cent might easily occur in a place like Chicago, or a place like Philadelphia.

Q. And when you as a physician realize that the typhoid fever in your town is increasing at a rate of 74 per cent, would you consider that of any importance, and would you make any effort to observe the cause, or ascertain the cause?

A. Yes sir, I would.

Q. And bring about conditions that would eliminate the increase?

A. I have just said I think it would be very important for the town, but I would not look for an outside cause.

Q. Would you look for a milk epidemic, or something of the kind?

11558 A. I would look for a well, or a milk infection, or some other local cause of epidemic.

Q. And you would make that observation for the entire four years, or eight years,—four years preceding and four years subsequent, would you?

A. I don't think the time would have any bearing on the question.

Q. If it came from a milk epidemic it would be localized, wouldn't it?

A. Milk epidemics usually do not get so broad, and do not last so long. I would not think of it as a milk epidemic.

Q. If a milk epidemic, it would likely last a long while and it would be localized?

A. It depends on what you mean, by localized.

Q. Localized in the vicinity, would be an infected well?

A. If there were a number of wells, each well would serve as a focus.

Q. And you would expect more typhoid in a district where there were more wells?

A. Yes sir.

Q. What would you say if you found out that there was 11559 less increase in typhoid in a district where there was a greater number of wells, than there was in a district where there were no wells?

A. I would look for some change in the treatment of the epidemic, then, the people might have been more careful in the use of the wells, might have the necessity to boil their water.

Q. And they might have had a different physician?

A. Yes sir, a different physician.

Q. You take those things into consideration?

A. Very much.

Q. Of more consideration than you would the water supply, regardless of what character that water supply was?

A. Of course I would suppose that the water is being examined all this time.

Q. Examined for what?

A. For its bacterial purity or the reverse.

Q. Doctor, confining yourself to the four years preceding and the four years subsequent, I will ask you if there hasn't been tables introduced by you, or by Prof. Jordan, referred to by you, in your examination which show an increase in the typhoid fever, in the city of St. Louis?

11560 A. There has been an increase.

Q. Even though you transfer all the remittent, intermittent, congestive, etc., fevers, into the typhoid column?

A. There has been an increase, yes sir.

Q. Based upon the number of cases per 100,000 of poulation?

A. Yes sir.

Q. What are the conditions in New Orleans, so far as climatic influences over various fevers are concerned, that do not pertain to the city of St. Louis?

A. New Orleans is in a much more malarial climate.

Q. Now how far does that malarial climate extend to the north, from New Orleans?

A. Well, it gets weaker as it goes north. The same climate does not extend any appreciable distance. It becomes weaker as you go up.

Q. It extends into Arkansas. I believe you said this morning?

A. Yes sir.

Q. Up as far as what?

A. Red River.

Q. Doesn't it extend through the bottoms of the Mississippi river, throughout the entire area of the State of Arkansas?

11561 A. Yes sir, you could even go further and say it extended all through the whole Mississippi valley, but it gets weaker as it goes further north.

Q. It is more effective in the summer time, than in the cooler seasons?

A. Yes sir.

Q. Is it not a fact that it is very prevalent throughout the entire state of Arkansas?

A. My information on that is not very complete. There is a good deal of difference of opinion among the local doctors, I find, from talking to them, and writing to some of them.

Q. Is it not a fact that it was more prevalent throughout the entire state of Arkansas three years ago and prior thereto than it has been since?

A. I do not know.

Q. You made no investigation of that character?

A. Not of that actual point, no.

Q. Is it not a fact that it was more prevalent prior to 1900, throughout the entire Mississippi Valley, than it has been since?

A. I do not know, myself. I would be very skeptical
11562 about any statements that were made on that point.

Q. You made no examination of that kind?

A. No sir.

RE-DIRECT-EXAMINATION BY

Mr. Todd.

Q. Doctor, in figuring out the percentage of figures, assume that the average for '95-6-7-8, of the percentages for the four years before 1900, was 21.05, and for the four years subsequent 36.5, and that the difference between these averages was 15.45, in figuring out the percentages by dividing 15.45 by 21.05 gives a percentage of practically 73 per cent, does that 73 per cent in your opinion, figured upon the basis that I have indicated in arriving at it, express a large increase in typhoid fever?

A. No, but I should say that I consider your method of getting at the result, very faulty. For example, the increase did not occur in a single year, but spread over a series of years, and it is not a figure that varies, up and down in those years,
but goes up steadily. If the 73 per cent had occurred be-
11563 tween '99 and 1900, I should say that either there must
have been a new focus of infection, or else that the old
focus must have been extremely badly handled but as it is spread over four years, and the ascent is gradual, and really began a year before the point of deviation, I still adhere to my former statement that it is not a great increase.

Q. You understand that the figures you are now testifying to are figures based upon the estimation that the typhoid fever death rate as reported in the house statistics, and estimated, do not include the other heading of typhoid fever?

A. Yes sir.

Q. In figuring out the per cent of increase does the average give as correct an idea as to the relationship existing between each year?

A. No.

Q. Will you figure the per cent of increase from 1898 to 1899, in percentages?

A. 34.7.

Q. Will you figure the per cent of increase from 1899 to 1900, in percentages?

A. 25.3.

11564 Q. Will you figure the per cent of increase from 1900 to 1901, in percentages?

A. 14.7.

Q. Will you figure the per cent of increase from 1901 to 1902, in percentages?

A. 9.5.

Q. Will you figure the per cent of increase from 1902 to 1903, in percentages?

A. 26.7.

Q. From these percentages of increase, taking it by the year, which year shows the greater increase over the previous year?

A. The first one.

J. Taking these percentages of increase by the year, what is your opinion as to whether they are large increases, or not?

A. No, they are not large increases.

Q. What is your opinion as to the validity of figuring the increase of typhoid fever in a community, in basing the percentage of increase upon the average per cent of increase for a given period?

11565 MR. JEFFRIES: I object to the question, because the witness is not an epidemiologist, or a sanitarian.

A. Well, I think I can answer that as a clinician. The percent for periods of time is an artificial one. There might be local conditions in any one year that would offset the average too much. In all such statistics there is a very serious error, depending upon the comparatively limited number of cases that we have to deal with, so that the difference in any one year would offset the average too much. So that I always work those things out on scales, because the scale, taken year by year, gives a better idea of the course of the diseases than a bunch of years, even reduced to a scale.

Q. These statistics which have been assumed as coming from the column of typhoid deaths, and not the typho-malarial, etc. deaths, in St. Louis, do you regard as correctly giving the typhoid deaths in the city of St. Louis?

A. The reports of typhoid deaths, alone?

Q. Yes sir.

A. No sir.

11566 RE-CROSS-EXAMINATION BY

Mr. Jeffries.

Q. Taking the number of typhoid deaths per 100,000 population for 1897, at 23.4, as the highest number reported during any one of the four years immediately prior to 1900, compared with the average number of deaths for 100,000, for the four succeeding years, 1900, 1901-2 and 3, please state the percentage of increase or decrease?

MR. TODD: I object to the question as affording no proper method of comparison, to compare one year with the average per cent of four years not separate, and wherein three years have intervened.

MR. JEFFRIES: I will admit that by taking the highest number occurring in any one of four comparative years prior to 1900, that no proper conclusion could be drawn, but that an error in that conclusion or result reached would be in favor of defendants and not the complainant, and therefore, as a precautionary measure will afford a more liberal application of the probable results of the two periods.

A. I get an increase of 55.99 per cent.

Q. What is the percentage of increase or decrease in the number of deaths reported per 100,000 population for the
11567 highest year during the period of '96 to '99 inclusive, and from 1900 to 1903, inclusive?

A. 98 per cent increase.

Q. Now, what years did you employ in that calculation?

A. The years 1897 and 1903.

Q. I will ask you if the result shown on this table for the four years from '96 to '99, does not show that there was an alternate increase and decrease year by year in this to wit, '96, 20.2; '97, 23.4; '98, 17.3; '99, 23.3, and that since 1899, to wit, the years 1900 to 1903 inclusive, there has been a continual increase?

A That is right.

RE-DIRECT-EXAMINATION BY

Mr. Todd.

Q. If the percentage of increase in '99 over '98 was 34.7, in 1900 over '99 was 25.3; in 1901 over 1902 was 14.7; and in 1902 over 1901 was 9.5; in 1903 over 1902 was 23.7, would the fact that the Exposition in the city of St. Louis was going on in these years, in any measure account for the difference in increase of 1903, over 1902?

MR. JEFFRIES: I object to the question for the reason 11568 that it calls for an answer impeaching the testimony of this witness in his direct examination in which he stated that it was a fact, and it is conceded by counsel to be a fact in this instance, that enterprises such as World's Fairs have the effect to cause physicians to fail to report typhoid fever as true typhoid, and causes them to report it in some other column.

MR. TODD: In view of counsel's explanation, I will not press the question.

GEORGE DOCK.

ADJOURNED until 10:00 o'clock A. M., March 14th, 1904.
March 12th, 1904.

STIPULATION.

It is hereby stipulated between the parties to this action, that the evidence heretofore taken in said action, before John A. Bishop, a Notary within and for the City of St. Louis, and State of Missouri, on the 24th day of October, A. D., 1903, being the evidence of LewIllys F. Barker, and consisting of 327 typewritten pages; and also the evidence taken on the 9th day 11569 of November, A. D., 1903, before Fred A. Burton, a Notary Public in and for the County of Cook and State of Illinois, being the evidence of C. D. Cassingham, Frank L. Stevens, and Walter George Sackett, consisting of twenty-eight typewritten pages, which was taken before Notaries instead of before the Commissioner, for the accommodation of the witnesses named, all of which said testimony is this, the 12th day of March, A. D., 1904, presented to the Commissioner herein, shall be received in evidence upon the trial of this action, the same as though such evidence had been taken before said Commissioner, Frank S. Bright, appointed by said Supreme Court, it being understood that each party reserves all objections to said evidence, which were made and noted at the time said evidence was taken, and that this stipulation is not to be regarded as a waiver of any such objections, and further, that in the printed record of said case, such evidence shall be incorporated.

SAM B. JEFFRIES,
Ass't Att'y Gen'l of Mo. for Complainant.
JAMES TODD,
Solr. for Sanitary District of Chicago.

Which said evidence is as follows:

Southern Hotel, St. Louis, Missouri.
11570 10:00 A. M., Saturday, October 24, 1903.

Parties met pursuant to agreement.

Present:

Attorney-General Crow,
Mr. Jeffries,
Attorney-General Hamlin,
Mr. Todd.

11571 LEWILLYS F. BARKER,

called as a witness in behalf of the defendants, being first duly sworn by John A. Bishop, a Notary Public within and for the city of St. Louis and State of Missouri, testified as follows:

DIRECT-EXAMINATION,

By Mr. Todd.

Q. What is your name?

A. Lewellys F. Barker.

Q. Where do you reside?

A. Chicago, Illinois.

Q. What is your business?

A. I am a profesosr in the University of Chicago.

Q. How long have you been connected with the University of Chicago?

A. A little more than three years.

Q. In what capacity are you connected there as a professor?

A. I am professor in the medical faculty, temporarily in charge of the department of anatomy, pending the establishment of a research department of internal medicine.

Q. How long have you been in charge of that department?

A. Ever since I came to Chicago.

11572 Q. What did you do prior to coming to Chicago?

A. I was nine years associated with the medical faculty of Johns Hopkins University at Baltimore, Maryland.

Q. In what capacity?

A. My first year I was an assistant to Professor William Osler of the department of internal medicine; then for two years I was fellow in pathology and bacteriology with Professor Welch, and then I was appointed to an associateship in anatomy with Professor Mall; then to assistant professorship in anatomy, and during my last period in Baltimore I was made associate professor of pathology with Dr. Welch of Johns Hopkins.

Q. Prior to your connection with Johns Hopkins University, what did you do?

A. I was a year as interne or house physician and surgeon in the Toronto general hospital, immediately after my graduation in medicine.

GENERAL CROW Toronto, Canada?

A. Toronto, Canada, yes sir.

Q. MR. TODD: From what school of medicine did you graduate?

A. The University of Toronto.

Q. Did you take an academic course prior to that?

A. No, I had a summer college course, but not the A. B. course. 11573

Q. After you graduated from the medical school at Toronto where did you go?

A. I went for one year in this hospital in Toronto, as the acting house physician and surgeon, then I went immediately to Johns Hopkins and was there for nine years and then came to Chicago; but I was away from Baltimore at various periods studying in Germany and on various commissions.

Q. What schools in Germany did you attend?

A. I spent most of my time at the University of Leipsic.

Q. Any other school?

A. I visited other schools, but did no special work in other places.

Q. What commissions were you on while connected with the Johns Hopkins University?

A. The first commission was one established by the State Board of Health of Maryland. Dr. Flexner and I were sent to the Loona County Valley to study an epidemic of a peculiar disease, the diagnosis of which seemed uncertain, but which turned out to be epidemic cerebral spinal meningitis. Then in 1899—

Q. Just before going to that, describe what you did in the investigation of that epidemic—briefly?

A. We proceeded to the district and found a large number of people of various ages ill of the disease, examined 11574 them clinically, made microscopic and bacteriological examinations of the blood and feces and urine and were successful in getting autopsies of some of the cattle dead of the disease and of making bacteriological examinations of the tissues after death,—examinations which resulted in an absolute determination of the nature of the infection.

Q. From where did the infection come?

A. In the epidemic of cerebral spinal meningitis?

Q. Yes?

A. No one knows. It is due to a micro-organism, but just how the micro-organism gets into the membranes of the brain and spinal cord, no one is just quite sure. There are theories about it but it is not settled.

Q. Not established?

A. Not absolutely established.

Q. Then what other commissions have you been on?

A. In 1899 the Johns Hopkins University sent Dr. Flexner and myself as special commissioners to study the tropical diseases in the Philippine Islands, and incidentally to study the epidemics of plague and beri beri in Hong Kong, India 11575 and Japan.

Q. How long were you on this commission?

A. We were six months on that commission.

Q. Relate what you did and what the results of that investigation were?

A. In Japan we were fortunate enough to visit Gute's laboratory and meet there Shiga who worked out the bacillus of acute dysentery in Japan. That proved to be a very important visit for us, for later in Manila we were able to isolate some of the cases of dysentery in those islands, with apparently the same bacillus as Shiga had isolated in Japan. In Manila too, we had an opportunity of studying an epidemic of 200 cases of beri beri, at Cavite, seven miles from Manila.

Q. What is beri beri?

A. Beri beri is a disease which occurs in two forms, the dry form and the wet form, so-called, the dry form being characterized by degeneration of the nerves or paralysis and loss of sense. The wet form being characterized by dropsical confusions in different parts of the body, a very curious disease the nature and etiology of which are not clearly established as yet.

In Manila there was abundant opportunity for the study of the three diseases very prevalent in the Island, namely, typhoid fever, malaria and the acute tropical dysentery, and
11576 we were able also to not only study a large number of
cases of leprosy, but to make biological examinations and autopsies of a number of lepers dead in various stages of the disease.

Q. Give the details of the investigations, doctor made in the Philippines, and the conclusions arrived at, if any were arrived at by you?

GENERAL CROW: With reference to what?

FR. TODD: To the diseases which he investigated there.

GENERAL CROW: There is no use in encumbering the record with all these other diseases; he can state the facts of his investigation. Do you want to put it all in?

MR. TODD: I want to put it in. Make it brief.

A. Well, in brief, through the courtesy of the Surgeon-General of the Army and of the Navy we had access to all the army and naval hospitals, and also to the native hospitals and Spanish hospitals, and the studies were clinical, including microscopic and bacteriological studies, and when deaths occurred we made autopsical and bacteriological examinations. The most important result of the trip is the special work of my colleague, Dr. Flexner, who was getting out the serum for the treatment of infections with this dysentery bacillus which we all hope may be helpful in abating that infection.

Q. What was the result of the investigations in regard to the typhoid fever made there?

11577 A. The result was the confirmation of the studies of typhoid elsewhere. Nothing especially new came out of our study of typhoid in Manila.

Q. What other investigation did you make in Manila aside from this that you have stated?

A. I think those were the principal investigations.

Q. Where else did you make investigations?

A. When we were at Hong Kong we were permitted to make autopsies on cases of plague and also bacteriological studies of cases of plague, but we had a far better opportunity in India where we saw eight hundred cases of plague in one day at Poona.

Q. What are the characteristics of the disease known as plague?

A. In the majority of cases a swelling occurs either in the groin or in the arm pit or neck, due to an infection of the lymphatic glands with the bacillus of the plague—the plague bacillus.

Q. Is that a contagious disease?

A. Yes, a very contagious disease.

Q. And how is the bacillus transmitted?

A. The absolute details are not established, though the probability is that insects transfer it from infected animals, especially rats to human beings.

11578 Q. What kinds of insects?

A. Possibly fleas, but it is not established.

Q. To what extent was the investigation carried on in India?

A. In India we spent six weeks—five weeks visiting various cities. It was a combination of pleasure trip with an investigating trip and our observations in India were chiefly clinical and a viewing of autopsies. The main benefit of the trip in India was to see the really great epidemic, which was the first great epidemic we had ever seen,—800 cases every day, with a patient coming in at the front door every eight minutes, and a dead one being carried out the back door every ten minutes.

It was an impressive sight rather than anything else. One could realize what a great epidemic would be.

Q. Have you been appointed on any other commissions except those by the Johns Hopkins University?

A. Yes, the first year I came to Chicago I was appointed by the Secretary of the Treasury in Washington, along with Professor Flexner of the University of Pennsylvania, and Professor Novy of the University of Michigan, to proceed to San Francisco and investigate the disease prevalent there among the Chinese, and to ascertain whether or not it was bubonic plague.

Q. Did you make a report upon your investigation?

11579 A. Yes, an extensive report was made to the Surgeon General of the Marine Hospital service in the department of the treasury, establishing the existence of the plague in San Francisco. We saw several cases of the disease during our visit, and made pathological and bacteriological examinations, and animal experiments and proved absolutely that the disease was bubonic plague.

Q. Have you investigated any other epidemics that those that you have described?

A. Well, in Baltimore of course, during the whole nine years, I had the opportunity of studying the epidemics of typhoid that existed in the city. Typhoid is quite prevalent at various times of the year, especially in the spring and autumn, as was also malaria in Baltimore, so that I had the opportunity there of becoming very familiar with both diseases.

Q. To what extent did you investigate the typhoid disease and malarial conditions in the city of Baltimore?

A. To the extent of one giving all his time to scientific work in a pathological line, and the investigation of cases coming into autopsies and coming into the wards of a hospital, which was given over largely to the search.

Q. Will you describe the conditions that obtained in Baltimore and the conclusions that you arrived at as to the cause of the typhoid?

11580 A. There seemed to be no doubt from observation of the conditions that the water supply of Baltimore is a polluted supply, and that at any rate a majority of the cases of infection was water-borne. Doubtless some of the cases were cases of so-called secondary infection of typhoid from contact or from environment or food stuffs.

Q. Have you made any studies of the question of typhoid fever?

A. Yes sir.

Q. What is the cause of typhoid fever—cause or causes of typhoid fever?

A. The reception into the body of a susceptible individual of a sufficient number of virulent typhoid bacilli.

Q. What are the means by which these bacilli are transmitted into the body of a human being as determined by scientific investigations as of today?

A. In a majority of cases through the mouth—by far the majority I should think—more than ninety-five per cent of the cases through the mouth.

Q. Through what means?

A. Through the drinking of polluted water, or of infected food or through the contact of fingers or other objects contaminated with typhoid bacilli.

11581 Q. What are the means by which the food becomes infected?

A. The food might be infected either from water which was already infected, or by contact of other materials, like fingers that had come into contact with typhoid excreta, typhoid urine or typhoid feces or typhoid infected dust.

Q. Do you know whether flies are in any way responsible for the spread of typhoid fever?

A. Yes, there is a great deal of evidence that flies can carry typhoid bacilli from one place to another; flies alighting upon typhoid excreta can contaminate their legs with typhoid bacilli and alighting upon food can leave typhoid bacilli upon the food.

Q. Do you know of any instances where epidemics have originated from that source?

A. Yes, it seems extremely probable that some of the more localized groups of cases in the city of Chicago have been due to infection by flies. The studies of Dr. Alice Hamilton point in that direction.

Q. Are you acquainted with the results of the investigation of Dr. Hamilton?

A. Yes.

Q. When were these investigations made?

A. Within the last two years, in the city of Chicago.

11582 Q. What are the facts connected with that investigation?

A. Our investigation was an experimental investigation, proving in the first place that flies can carry the organisms from one place to another and cause infection of nutrient media in that way. Then she demonstrated the possibility of flies having come in contact with typhoid excreta in the city of Chicago in the region infected—

MR. JEFFRIES: Is the witness testifying from a publication now?

MR. TODD: Yes.

MR. JEFFRIES: It would be well to have him state the publication and the source of his information, and show the probability of food infection in this way.

Q. Where did you get the information from?

A. From conversations with Professor Hektoen of the department of pathology under whose direction the work was done.

GENERAL CROW: Is that all the source of your information?

A. That is my source of information. I consider it the best possible one.

GENERAL CROW: Well, we move to strike all that with reference to experiments made by Dr. Hamilton, out of the record, for the reason that it is simply hearsay testimony.

MR. TODD: Q. Has her investigation been published,
11583 do you know—the result of her investigation?

A. Yes sir.

Q. Do you know where?

A. I cannot give you the reference. It would be very easy to get it though.

Q. Dr., will you state what is remittent fever, intermittent fever, typho-malarial fever, congestive fever and simple continued fever?

A. Those are all clinical rather than pathological terms, and date back to the time when classifications had to be made on symptomology rather than upon pathology and etiology.

The remittent fever was the term given to a fever which had exacerbations and declines without reaching the normal, as a rule, while intermittent fever—

GENERAL CROW: Without the temperature reaching normal?

A. Without the temperature reaching normal.

And intermittent was the term given where the temperature went up high and came down to the normal, then up high again and down to normal.

Typho-malarial fever was a term given to cases which were believed to be by many, a fever distinct from typhoid, and distinct from malaria, a fever which ran the course of typhoid, but which had many symptoms resembling those of malaria
11584 while congestive fever was a very vague term used in different ways by different clinicians and was usually associated with the idea of congestion of the head, rush of blood to the head, along with the fever, while simple continued fever was a term applied by, as a rule, the less well-educated physicians, to mild forms of fever running over a considerable period, generally over more than ten days or two weeks. It was a term used by people who believed that such fevers were not typhoid and not malaria, but simple continued fever. They didn't know exactly what it meant. Now all of those terms are given up by good clinicians at the present time; there is no such thing as a remittent fever as a clinical entity any more. It is either typhoid or malaria, or acute tuberculosis, or some other infection, and usually it is possible during life to determine that a case of so-called remittent fever, or intermittent fever in the same way, may be one of several diseases perhaps. Most often what is designated intermittent fever is malarial fever, but cases of typhoid fever are often mistakenly designated as malaria, intermittent, etc. The congestive fever might be one of

various things; sometimes it is typhoid and sometimes it is malaria. Sometimes it is something else.

Simple continued fever may be typhoid. I think perhaps most often it is—

11585 G9NERAL CROW: Mild cases?

A. A mild case of typhoid fever. It may be something else. None of those terms would be used now by a skilled clinician.

Q. Have you made a special study of fevers?

A. In as far as that a man working in internal medicine a large part of his time, and in pathology must make a study of fevers.

Q. Have you examined the statistics of typhoid fever in St. Louis as given by the health reports of St. Louis?

A. I have.

GENERAL CROW: For what time?

MR. TODD: For the period of—from 1890 to the present time.

A. I have. I have an excerpt from the reports here giving the figures of the Board of Health.

Q. Are those figures taken from the official publications of the Board of Health of the city of St. Louis?

A. They are.

Q. Have you the statistics of typhoid malarial fevers?

A. I have the statistics under the head "remittent, intermittent, typho-malarial, congestive and simple continued fevers. They are grouped together under one head in the official report.

11586 Q. Will you read these statistics for the different years that you have them, as taken from the official reports of the Board of Health of St. Louis?

GENERAL CROW: For what disease; for typhoid fever?

MR. TODD: For the different fevers—these two groups.

A. (Reading):

Year.	Typhoid fever.	Remittent, Intermittent, Typho-malarial, Congestive and simple continued fevers.	Total.
1890	140	226	366
1891	165	216	381
1892	441	326	767
1893	215	284	499
1894	171	179	350
1895	107	155	262
1896	106	177	283
1897—the figures vary slightly in different reports; in one report:	125	173	—Total 297 or 298 according to the report.
1898	95	134	229
1899	131	148	279
1900	168	112	280
1901	198	80	278
1902	222	102	324

11587 Then I have the death rates—the typhoid fever death rate in St. Louis as estimated from the official reports.

GENERAL CROW: Estimated?

A. As figured out from the official reports—or calculated, if you like. It is simply a mathematical case.

GENERAL CROW: Those were cases and not deaths you gave?

A. These are actual deaths. This is the death rate.

GENERAL CROW: For what?

A. For the city of St. Louis.

GENERAL CROW: Yes, but for what diseases; do you mean total mortality?

A. For typhoid fever alone, and total mortality as compared in parallel columns:

11588

ST. LOUIS.

		Death rate per 100,000.	
Year.	Population.	Typhoid alone.	Total death rate.
1890	451,709	30.9	81.2
1891	462,753	35.6	82.3
1892	474,077	93.	161.7
1893	485,568	44.2	102.7
1894	497,565	34.3	70.3
1895	509,740	29.9	51.3
1896	522,225	20.2	54.1
1897	533,762	23.4	65.6
1898	548,590	17.3	41.7
1899	561,510	23.3	49.6
1900	575,238	29.2	48.6
1901	589,315	33.5	47.1
1902	603,736	36.7	53.6
1903	618,510		

The figures of course are not available for the death rate, and I have for comparison the report of deaths from Baltimore during four or five years under these two similar groups of diseases.

In the year 1899, typhoid fever alone, 153; remittent, intermittent, etc., 48,—total, 201.

1900, typhoid fever alone, 182; remittent, intermittent, etc., 51; total, 233.

The population in that year was 508,957.

In 1901, typhoid 141; remittent group, 35; total, 176.

In 1902, typhoid 220, remittent group, 31; total, 251.

11589 MR. TODD: Where were those statistics from Baltimore secured from?

A. From the health reports of the city of Baltimore.

Q. Do these reputed causes of death which you have read into the record appear in the vitality statistics of the Board of Health reports of the city of St. Louis?

A. Yes.

Q. With the exception of Baltimore?

A. Yes.

Q. What is your opinion as to the justification of including these under one head as is done in the St. Louis health reports?

A. Well, I think that under the circumstances the medical practitioners, trained as they are, there is nothing for the Health Board to do but to include them as they do, under that heading, at the same time—

GENERAL CROW: Under which head?

A. I mean the remittent, intermittent, typho-malarial, congestive and simple continued fevers. Those reports are sent in by the physicians to the Board of Health as deaths from those causes, and the Board of Health cannot very well do anything but tabulate them in that way. Of course from what I have said, it is clear that in my opinion those cases are nearly all cases of something else, cases of some disease that could 11590 be diagnosed by skilled physicians—

GENERAL CROW: Mostly typhoid?

A. Mostly typhoid, and some of them perhaps acute tuberculosis, but chiefly typhoid. In fact I think the addition of the two columns, the typhoid column and the remittent, intermittent, typho-malarial, congestive and simple continued fevers, would give a truer typhoid death rate in the city of St. Louis than any other of the statistics that we could get.

Q. MR. TODD: Is it probable that any of the deaths reported from these causes during a series of years might with modern methods of diagnosis appear under some other heading?

A. Yes, I think that the majority of those under the heading of remittent, intermittent, typho-malarial, etc., if examined carefully, by skilled clinicians would be definitely diagnosed as specific diseases which we know about.

Q. Are there any other reasons on the clinical side for confusion of diagnoses in dealing with these diseases?

A. Yes, there are reasons especially where men are not trained in the most modern methods of diagnoses where it would be extremely difficult for a practitioner who has not been trained in the recognition of the malarial parasite, to decide between many cases of malaria and many cases of typhoid fever.

It would be extremely difficult for a man who is not 11591 familiar with the modern agglutinative and bacteriolytic tests to distinguish between many cases of typhoid fever and cases that are not typhoid, but resemble it.

Q. What is the final and distinguishing differential test for typhoid fever and for malaria?

A. The most important clinical test we have for typhoid fever if I may say, a single test, the most important single test though no one test is sufficient in my opinion to rely upon always in the diagnosis of typhoid, the most important single test is the Widal reaction or agglutinative test. More important still is the symptom complex along with the presence of the Widal reaction.

GENERAL CROW: You mean the condition of the patient?

A. The whole condition of the patient, the temperature, apistaxis, the mental condition, the abdominal distention, the tenderness and gurgling in the abdomen, the character of the stools, the enlargement of the spleen, the rose spots on the abdomen, the character and time of disappearance of the headache, the onset of the delirium when it occurs, and so forth.

Q. For malaria what is the final distinguished differential test for that fever?

A. For malaria, the one test above all others, is the
11592 demonstration in the blood or tissues of the patient of
the malaria parasite, by microscopic observation.

Q. What is the cause of malarial fever?

A. There are three great varieties in malarial fever, each due to a specific protozoan parasite, easily recognizable under the microscope; three varities easily distinguishable from one another. The nature of the symptoms being easily predicable by one familiar with the life history of the parasite by simply an examination of the blood—microscopical examination of the blood.

Q. Are these tests always applied by physicians?

A. Unfortunately not, for only a comparatively small percentage of physicians are trained in the method of making the examination.

Q. Are the symptoms of these diseases baffling so that even an experienced physician might sometimes be deceived in his diagnosis unless modern tests were applied?

GENERAL CROW: We will admit all that.

A. Yes sir, that is true.

MR. TODD: In view of all these facts as you have related them, does it appear from the figures given in the report of the St. Louis Health department, that there has been an in-
11593 crease of typhoid fever in the years 1900 to 1902 inclusive as compared with the ten preceding years, in the city of St. Louis?

A. It is absolutely certain if these statistics are reliable, that there has been no increase.

Q. What do the statistics show?

A. The statistics show that the total number of deaths reported from typhoid and the remittent group together, run along at a tolerably constant figure. The figures, however, show in the typhoid fever column alone an increase in the number of typhoid cases; quite a marked increase during the last three years, from 1900 to 1902. They also show quite a marked diminution in the remittent and intermittent group during the last three years. There has evidently been simply a transfer from the remittent column to the typhoid fever column. In other words, typhoid fever has been diagnosed more often during the last three years, than it has in the last preceding years. There has been no greater number of cases, but the diagnosis appears to have been better. That the diagnosis is not yet good by many of the physicians in St. Louis is obvious from the large number of cases still reported in the remittent group.

GENERAL CROW: Are you talking about cases or deaths?

A. Deaths. When I say cases here I mean deaths every
11594 time. And I have no doubt that the discrepancy of cases existing would be infinitely greater than the death report shows.

Q. MR. TODD: Will you read into the record the statistics upon which you base that information, calling particular attention to the conditions before 1900 and since 1900?

A. Well, whereas, with the exception of obvious epidemic years the typhoid from 1890 to 1899--the death rate varies between 95 and say 215.

GENERAL CROW: That is per 200,000?

A. No, this is the total number of deaths in the years.

MR. TODD: You say the epidemic years. What years do you have reference to?

A. The year 1892 was obviously an epidemic year of typhoid fever as there were 441 deaths reported from typhoid fever in St. Louis that year.

Q. Excluding that year?

A. Excluding that year the death rate runs along and varies between 95 and 215, and there are two years with 106 and 107 deaths from typhoid.

Now in 1900, the deaths from typhoid are 168;

1901	198
1902	222

And whereas in the remittent group the lowest number
11595 of deaths before the year 1900, in that group, is 134,
the highest number of deaths being in the epidemic typhoid year, 326, just where we would expect it to be, but in 1900 these numbers drop away down to 112 for 1900; and to 80 for 1901, almost one-half what it was in any year preceding 1900, and in 1902, to 102. The total numbers, however, for the whole ten years run along in a fairly constant way.

GENERAL CROW: In the two groups?

A. The total numbers for the two groups added together run along in a fairly constant way, indicating clearly to one who is familiar with the way these deaths are diagnosed, that there has been a transfer during the last three years from the remittent group to the typhoid group, a transfer which is most commendable because it shows that a more accurate diagnosis has been made of typhoid fever during the last two or three years. I mean by that, the physicians have reported to the health department more cases of typhoid and fewer cases of remittent, but that there are still far too many cases being reported by the physicians of St. Louis as remittent, intermittent, typho-malarial fever, congested, etc., is clearly shown by comparison with the Baltimore typhoid death rate. The conditions of the two cities are
not dissimilar, and typhoid and malaria exist in all prob-
11596 ability in about the same proportions in the two cities,
but whereas in Baltimore the typhoid fever is very much more abundant, as compared with the remittent group, the explanation in my opinion, is that typhoid fever is better diagnosed

in Baltimore than it is in St. Louis, and that is not surprising because very important studies have been made durng the last ten years in Baltimore on typhoid, and on malaria, perhaps the most important studies in the country, and the city is being repeatedly filled with young practitioners who have been trained under the men who have made these special investigations in typhoid and malaria, and nearly all young men who go out into practice in Baltimore from the Johns Hopkins University, have a skill in making the diagnoses between the two diseases so that I feel sure that there is still a large number of cases in this city being put in the wrong list; that physicians are not yet diagnosing typhoid fever as they ought to do.

Q. From your investigations and consideration of the vital statistics of the city of St. Louis, has there been an increase in your opinion, in the typhoid death rate since 1900 over the death rate that existed in St. Louis for the period of five years prior thereto?

A. No, there has not been an increase.

11597 Q. Assume, professor, that in 1900, or the latter part of 1899, the Board of Health of the city of St. Louis sent out a specific circular to all the practitioners in the city of St. Louis, calling particular attention to the typhoid conditions existing here, and asking for a special report upon cases of typhoid fever, would that in your opinion have any influence—

A. Yes, I think it would—

MR. JEFFRIES: Wait a minute. I object to the question for the reason that it is not one based upon the judgment of an expert, or calling for an expert opinion, but one which the court can understand and take into consideration without being interpreted by a layman or any other person.

MR. TODD: Answer the question, professor?

A. I think it would for this reason, that it is not an uncommon practice among physicians to designate cases that they regard as typhoid fever themselves, as remittent or continued, or typho-malaria, or malarial fever, for the express reason of not exciting too much the fears of their patients. I know that that has been done by physicians. Patients are afraid of typhoid fever, and they naturally beg of their physician to tell

them what the disease is, and sometimes when one actually feels
that the case is one of typhoid, he will say to the patient
11598 that it is remittent fever, or typho-malaria or something
of that sort, because he uses a clinical term which is
true. Typhoid fever has a remittent chart sometimes.

Q. Is there such a fever recognized by modern physicians equipped with modern researches, as typho-malarial fever?

A. The best clinicians avoid the term altogether for this reason: that it is now possible to tell in every case practically, whether we are dealing with real typhoid fever or real malarial fever, or as occasionally it has happened, a mixture of the two infections. There are a few cases in which the typhoid fever bacillus is invading the body at the same time that the protozoan malarial parasite is invading the body. If any case deserves to be called typho-malarial fever it is such a case which is a mixed infection, but the term as used formerly and as used generally, referring to the clinical course of the disease, a course that ran several weeks, like typhoid, but that had had marked exascerbations and diminutions of temperature, and associated sometimes with chills, is improper.

Q. How does the death rate from typhoid fever in the city of St. Louis as you interpret the vital statistics, compare with the statistics of Baltimore and other cities?

A. The death rate in St. Louis is not excessive as com-
11599 pared with Baltimore and corresponding cities.

Q. With what other cities have you compared them?

A. I have compared them with figures from Philadelphia, Boston and New York; and especially as compared with Philadelphia, the figures in St. Louis are very moderate.

Q. Are you acquainted with the epidemics caused by the water-borne diseases, such as typhoid?

A. In a general way, I am, yes.

Q. How far has the contagion of typhoid fever been shown to travel in a flowing stream?

A. Well, if one takes the extreme statement of one investigator, the maximum distance is about seventy or seventy-five miles. That view and assertion has not met with general acceptance, however.

Q. Are you acquainted with the general conditions which obtain from Chicago, the drainage canal, the Illinois river, the Mississippi and Missouri rivers, down to St. Louis, at the St. Louis intake?

A. Yes, in a general way.

Q. Have you given the subject of bacteriology any study?

A. Yes, I have studied it and taught it in Baltimore, but no special study since I came to Chicago.

11600 Q. What position does the science of bacteriology occupy in regard to the ascertainment of the purity of waters?

A. A most important position, for it has to deal with the presence or absence of disease producing germs in water.

Q. What position does chemistry occupy in what is known as sanitary science?

A. A very important position also, for it permits one to draw conclusions as to the extent of contamination with organic matters, including sewage.

Q. Are you acquainted with the life of the typhoid bacillus?

A. Yes, I may say that I am. I have worked a good deal with it myself, and I am more or less familiar with what has been written about it.

Q. What is your opinion as an epidemiologist and pathologist as to whether a typhoid bacillus lying in the sediment of a stream for a period in excess of sixty days, would be able, if taken into the human system after that period, to cause typhoid fever, if said bacillus should be removed and placed in the drinking water used by a person?

A. In my opinion it would be harmless.

Q. Assume that the distance between Chicago and the intake tower of the St. Louis waterworks, at the chain of rocks, is 357 miles; the intake tower of the St. Louis waterworks being located about ten or eleven miles above the Eads bridge, 11601 and that the St. Louis intake tower is 1,500 feet from the Missouri shore in the Mississippi river; what is your opinion as an epidemiologist and pathologist as to whether the sewage entering the drainage canal at Chicago, assuming that the same was typhoid infected, after traversing that distance of 357 miles, as to whether the pathogenic bacteria in the sewage of Chicago would be able to survive the journey from Chicago to the intake tower at the chain of rocks, as indicated heretofore, and be a menace and a danger to the inhabitants of the city of St. Louis?

A. In my opinion they could not be.

Q. What is your opinion as to whether typhoid bacilli could survive the journey from Chicago to St. Louis, a distance of 357 miles, passing down the Illinois river, passing by Peoria, and Pekin, which receives a large discharge of sewage from the cattle sheds of the cities of Peoria and Pekin, Peoria being a city with a population of about 75,000 inhabitants, and getting into the water supply of St. Louis, and causing typhoid fever?

MR. JEFFRIES: We object to the question for the reason that the witness is left to assume in his answer any amount of discharges into the Illinois river at Peoria from the cat- 11602 tle sheds of that city, the question not containing the number of cattle fed or the amount of matter discharged into the river at that point.

MR. TODD: I will change that. What is your opinion as to whether typhoid bacilli could survive the journey from Chicago to St. Louis, a distance of 357 miles, passing down the Illinois river, passing by Peoria and Pekin, which receives a large discharge of sewage from the cattle-sheds of the cities of Peoria and Pekin, wherein 18,000 head of cattle are fed annually, and the excreta from these cattle, aggregating 1,080,000 tons of feces and urine, thrown into the Illinois river at these two points, besides the sewage from the city of Peoria, which is a town of about 75,000 inhabitants, and getting into the water supply of St. Louis and causing typhoid fever?

MR. JEFFRIES: That is objected to for the reason that there is no evidence showing that there are 18,000 head of cattle fed at Peoria and Pekin in any one year since the opening of the canal, and for the further reason that the evidence does show that there are less than 12,000 cattle fed, and that the number is decreasing from year to year.

MR. TODD: In reply to that I desire to state that the 11603 testimony of Wolfner, a distiller at Peoria, was to the effect that there were 12,000 head of cattle fed in the city of Peoria, and the mayor of Pekin testified that there were 8,000 head of cattle being fed at Pekin this year.

Q. (Question read).

A. There is no evidence in the literature which would make it seem probable indeed. All the evidence that I know would oppose the probability or even possibility of that occurring, and moreover, the proof that it did occur could not be brought unless every typhoid bacillus now entering the stream between say Lockport and St. Louis, could be excluded from the river. In my opinion typhoid fever bacilli would not survive the journey.

MR. TODD: Q. As an epidemiologist and pathologist, do you consider the sewage of Chicago entering the drainage canal and the Illinois river, which in turn empties into the Mississippi river, a menace and a danger to the inhabitants of the State of Missouri, and the citizens of the city of St. Louis taking their water supply from the intake tower at the chain of rocks, in the Mississippi river?

A. In my opinion, no.

Q. Assume that an epidemic of Asiatic cholera should break out in the city of Chicago, and the sewage of Chicago should enter the drainage canal and the Illinois river, what is your opinion as to whether or not the germ of Asiatic cholera would survive the journey from Chicago to the intake tower at the chain of rocks, a distance of 357 miles, and be a menace and a danger to the inhabitants of the citizens of St. Louis? 11604

A. In my opinion it would not.

Q. What causes in your opinion would lead to the death of the typhoid bacillus in river water?

A. In my opinion there would be two main factors, the oxidation that occurs along with sedimentation, and the unfavorable food relations—three factors—and the third, perhaps the most important factor of all, the influence of saprophytic bacteria in the stream.

Q. Would the introduction of this mass of organic material from the stock yards and distilleries of Peoria favor or hinder the disappearance of the typhoid bacillus in your opinion?

A. In my poinion it would favor the disappearance.

Q. If the disease of tetanus should appear in Chicago, what is your opinion as an epidemiologist and pathologist, as to whether the inhabitants of St. Louis are in danger of infection from tetanus by reason of the operation of the Chicago drainage canal?

A. In my opinion there would be no danger of infection
11605 by tetanus. It doesn't occur in such a way at all.

Q. From anthrax?

A. In my opinion there would be no danger.

Q. From the bacillus enteriditis sporogenes?

A. There would be no danger in my opinion.

Q. What is this bacillus enteriditis sporogenes?

A. I take it that by that you mean the bacillus which is identical with the bacillus aerogenes capsulatus of Welch and Nuttall, a facultative anaerobe which is capable of causing infection in human beings, cases of which I have studied, but which is not, as far as we know, a water-borne disease, and moreover, is a rather rare disease. The bacillus is a spore-producing bacillus, but I cannot conceive of cases of the disease occurring in Chicago being a menace in any way to the citizens of St. Louis.

Q. Do the figures on typhoid fever and related diseases in the St. Louis health reports admit of tracing any relation between the prevalence of these diseases and the opening of the Chicago drainage canal?

A. The only possible relation that I can see is the difference in diagnosis during the years mentioned, as concerns these two groups, of typhoid fever and the remittent group. As far as
the total number of deaths in those two series is con-
11606 cerned I can see no connection between the opening of
the drainage canal and the figures.

Q. What in your opinion from the standpoint of epidemiology would be the probable length of life of the typhoid bacillus introduced by way of the drainage canal into a sluggish river such as the Illinois river, flowing through a more or less densely populated country, and receiving successive increments of organic matter together with the associated saprophytic bacteria?

A. I should think from five to seven days.

Q. Does the death rate from typhoid fever in St. Louis indicate the use of an excessively polluted water supply in your opinion?

A. If you mean excessively as compared with the water supply of many American cities, I should say "No." If you mean excessively as compared with ideal conditions, I should say "Yes."

Q. How does the death rate from typhoid fever in St. Louis compare with that in other American cities using a well protected surface water as a source of supply?

A. The death rate in St. Louis is lower than in a number of such cities, if you mean by the term "well protected" what is ordinarily meant by that term in this country.

11607 Q. Assume, professor, that in the year 1900, the number of typhoid deaths reported from typhoid fever in all the cities lying tributary to the Mississippi river from St. Paul to the mouth of the Illinois river, was 311 deaths, on the Missouri river from Lincoln, Nebraska and Omaha, Council Bluffs, St. Joseph, St. Charles, Kansas City and Jefferson City, lying tributary to the Missouri river, was 108 deaths, and on the Illinois river and its tributaries exclusive of Chicago was 129 deaths, making an aggregate of typhoid deaths on these three rivers, exclusive of Chicago, of 548 deaths, and that the number of deaths in the city of Chicago for the year 1900 was 339 deaths, and assume that in point of distance Omaha is fourteen days, representing the average mean flow of the river from Omaha to St. Louis, from St. Paul the average mean flow of the river is seventeen days, and from Chicago to St. Louis intake on the Illinois river, is eighteen and a half days, representing the average mean flow, and assuming that the typhoid condition in the city of St. Louis for that year is due to a contaminated drinking water in large part, what would you say as an epidemiologist as to whether the cause of typhoid fever in the city of St. Louis could be attributed to the sewage of Chicago, in view of the vital statistics, assuming in this hypothetical question 11608 the typhoid fever existing upon the water-sheds of the three rivers, exclusive of the typhoid conditions in Chicago?

A. In my opinion it could not.

MR. TODD: I want to introduce into the record a tabulated statement of those statistics based upon the death report of typhoid fever in the cities on the Illinois river and its tributaries exclusive of Chicago, the Mississippi river and its tributaries, above Grafton; the Missouri river from Omaha to St. Louis, and the typhoid statistics annually from 1890 to 1902, of the city of Chicago and the city of St. Louis, most of these statistics having been proven by complainant, and verified by defendants, and the table will be verified by the sworn testimony of John J. McLaughlin, a witness sent by defendants to investigate the typhoid conditions in all the towns not testified to by witnesses for the complainant.

The purpose of introducing this into the record at this time is to get the typhoid statistics along the three watersheds and Chicago and St. Louis, in a concise form for reference, as well as to predicate a question to this witness.

The tables are as follows:

11609

Death Report from Typhoid Fever in Cities Lying Tributary to the Missouri River.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902
Lincoln, Neb........	33	21	23	15	14	12	13	4	13	10

11613 MR. TODD: Doctor, have you examined the tables of typhoid statistics which have been read in evidence, showing the number of typhoid deaths on the water-sheds of the Mississippi river from St. Paul to Grafton, and on the Missouri river from Omaha to St. Louis; and on the Illinois river and its tributaries exclusive of Chicago, and the typhoid death rate in the city of Chicago and the city of St. Louis?

A. I have.

Q. From an examination of those typhoid statistics as above indicated, what is your opinion as an epidemiologist as to the question of probable infection in the city of St. Louis from the typhoid conditions existing on the water-sheds of those three rivers, exclusive of Chicago and the infection from Chicago, assuming that the distance of the mean flow from Omaha is fourteen days; from St. Paul seventeen days, from Chicago eighteen and one-half days, as to the probability of infection from the different towns, upon the question of distance as to flow, rather than distance as to miles?

MR. JEFFRIES: I want to ask counsel if he means by probable infection the probable infection of the waters of the

Missouri and the upper Mississippi, or the probable infection of the waters of the Mississippi by the sewage of Chicago?

MR. TODD: I mean the infection in the water supply of
11614 St. Louis from the three rivers in question exclusive of
Chicago and the infection from Chicago.

A. In my opinion the probability of infection or pollution of the water supply of St. Louis, assuming the above, would be largest from those places within the mean flow of five to seven days. I don't know how to express that—from those places where the average flow or the mean flow is within five to seven days of St. Louis. I think the probability of infection or pollution from the great distances requiring more than twelve days for example, would be remote.

CROSS-EXAMINATION, by Mr. Jeffries.

Q. I understood you to say, doctor, you are now connected with the Chicago University?

A. Yes sir.

Q. And have been connected with that institution how long?

A. Three years.

Q. What position do you now occupy?

A. Professor and head of the department of anatomy.

Q. Professor and head of the department of anatomy?

A. Yes sir.

Q. How long have you occupied that position?

11615 A. Since I came to the University.

Q. And before you came to that university you occupied what position?

A. I was associate professor of pathology in Johns Hopkins University.

Q. With Dr. who?

A. William H. Welch.

Q. And how long were you there?

A. In Baltimore?

Q. Yes?

A. I was in that position only one year.

Q. Now before that you were with Dr. Osler?

A. Yes, I was with Dr. Mall for a while, then with Dr. Welch for two years before that, and then with Dr. Osler one year.

Q. Now explain, doctor, what position you occupied and what relation you bore to these three gentlemen that you mentioned, in Baltimore?

A. With Dr. Osler I was an assistant in the Johns Hopkins hospital, mostly during clinical examinations in the out patient department, chiefly, and while with Dr. Welch in the first two years, my work was all bacteriology and pathology, and again while I was with Dr. Mall I was teaching anatomy, but my research work was largely in pathology and medical subjects and then in the last year in Baltimore my work was all in
11616 pathology and bacteriology again.

Q. Now your study and work in reference to pathology pertained practically to the study of the nature and character of diseases, did it not?

A. Nature, character, mode of spread and origin of diseases, yes sir.

Q. In your work in these institutions both as to the Chicago University and at Baltimore, your time was occupied in the laboratory was it not, and hospitals?

A. Laboratory and hospital almost entirely.

Q. You were not required in your work, while connected with these institutions, to visit various sections of the country to determine the source of any particular infection were you, or the source of the disease with which the patient was afflicted while in the hospital?

A. When working with Dr. Osler it was our custom, especially when a typhoid case or malaria case came in to search out if possible the origin of it, and we often went to the house from which the patient came and examined the conditions and tried to find out the origin.

Q. Now doctor, how many of those cases did you go to the house and search for the origin of the disease?

A. During my year with Dr. Osler?

11617 Q. Yes sir?

A. I haven't any idea.

Q. Well, can you approximate it?

A. Well I should say not less than ten and not more than forty times.

Q. And when you did search for the source of the disease you simply ascertained whether or not it was on account of being associated with some other patient or coming in contact with some other case, or whether or not it was caused by food supply or water supply, without reference to the source of the food or the source of the water, was it not?

A. We tried to ascertain all the conditions bearing on the case. It wasn't always possible to get at all of the conditions.

Q. Now did any of those cases come to your observation while connected with the institution at Baltimore from an epidemic of the particular disease then being studied?

A. Yes, typhoid fever is epidemic in Baltimore nearly every year.

Q. What is the great source of the typhoid epidemic in Baltimore that occurs annually?

A. The water supply is believed to be responsible for it.

11618 Q. Where does Baltimore get its water supply doctor?

A. There are different parts of the city which get different water supplies. The part that I was interested in particularly came from Lake Roland.

Q. How far is Lake Roland from Baltimore?

A. In exact miles I don't know. It takes about half or three-quarters of an hour to go out by the trolley.

Q. Would you say fifteen or twenty miles?

A. Oh no, not nearly so far. I should think five or seven miles perhaps.

Q. Do you know how large a body of water that lake is?

A. No.

Q. You have seen it?

A. Yes sir.

Q. Well in making an examination or study of that water as applied to the particular disease that you had under consideration and which was attributed to that water, did you take into consideration the volume of the water contained in the lake that furnished the supply to the particular locality that was infected with the disease?

A. The volume of water was discussed.

Q. Well now in that discussion—

A. But I took no part in it myself.

11619 Q. How is that?

A. I took no part in the discussion myself.

Q. Well in passing upon the question as to the cause or source of the infection and in exercising your judgment, was it not necessary for you to take that fact into consideration?

A. At that time I was merely an aider and helper in the laboratory.

Q. Then you made no examination with the view of determining for your own satisfaction?

A. The volume, no.

Q. As to whether or not the source of the infection that you were then examining, could be attributed to that lake?

A. I made no personal examination, no, of the waters. .

Q. So you cannot say then of your own personal examination, as an epidemiologist, that the water from that lake was the source of the infection, or of the epidemic?

A. It would not be necessary for me to make a personal examination to have that opinion.

Q. You formed that opinion from the effect of the water upon the people using it?

A. And the testimony of reliable witnesses as to the pollution of the water—as to the possible pollution of the 11620 water.

Q. Well, are you able to state from the information which you received, that that was in your judgment, as an epidemologist, the source of the epidemic, and that the water in that lake was infected?

A. It was my opinion that the cases of typhoid fever occurring among those who drank of the water from that district, from that water supply were due to the pollution of the water supply by typhoid bacilli.

Q. In other words that the epidemic occurring among the people who drank the water or who used the water from the lake it is your opinion then that the water in the lake was infected with typhoid fever germs?

A. Yes sir.

Q. Now you are of the opinion you say that that was the source of the epidemic?

A. Well I am of the opinion that that could have been responsible for it.

Q. But doctor, I understood you to say that you had examined conditions surrounding Baltimore, and had studied and that the study that you had given the situation was sufficient to enable you to form an opinion as an epidemiologist, as to the cause of the epidemic, and you attributed that cause to the pollution or infection of the water in the lake, is that
11621 true?

A. I don't know that I should have called myself an epidemiologist then; I was a very young man and beginning my studies in medicine and studying in a very modest way under directions at that time.

Q. Then doctor, you have never examined as an epidemiologist the origin or source of the typhoid epidemics that occur annually in the city of Baltimore?

A. If you mean personal examination of the shores of the lake and the rivers, that is true.

Q. I mean doctor, an examination such as would enable you to form an opinion which you yourself would be willing to rely upon as a reputable epidemiologist, as to whether or not the infection of the lake was the cause of the typhoid epidemics that appear annually in the city of Baltimore?

A. If I wished to pass as an epidemiologist on such a question I should certainly make a more careful examination than I did at that time.

Q. Well you do pass as an epidemologist, do you not?

A. Yes, I do now.

Q. Well, when was that that you made the little examination you did make of the typhoid epidemics at Baltimore?

A. Well, my examinations of the typhoid epidemics were
11622 chiefly of course clinical and pathological; they were being made all through my stay in Baltimore all through the nine years, and with that side of the pathology I am most familiar.

Q. That is with the clinical side?

A. Bacteriological and pathological side.

Q. Pathological and bacteriological side, without reference to the exterior physical facts that might surround the situation?

A. My study of that has been from the literature chiefly.

Q. In fact has been entirely from the literature, except the few instances which you mentioned in your direct examination with reference to conditions at Manila and other places?

A. Yes, as to the epidemics that I studied elsewhere.

Q. I believe you stated that you would not consider the information that you had with reference to the physical condition of the lake, its dimensions and volume of water, sufficient to enable you to form an opinion as to whether or not the water in the lake was the real source of the epidemic?

A. I would not require any such knowledge to form an opinion as to the source of an epidemic if I found that people were dying from typhoid fever who drank that water in large quantities.

11623 Q. And that, doctor, would be true without reference to whether or not the lake contained a sufficient volume of water to supply the city or that part of the city which was supplied with the water from that lake, with water, for one, two, three, four or five days or longer as the case may be?

A. I don't quite understand the question.

Q. In other words, I mean with that opinion that condition would hold good without reference to the fact that the lake might be sufficient to contain only a sufficient water supply for that particular district, for one or two days, or five or ten or twenty days. In other words, the volume of water would be of no material consequence?

A. I should put it this way; that the distribution of the cases of typhoid from a given water supply connected with a good water supply, would be sufficient to say that that water supply was responsible for the cases of typhoid. As to just what portion of the water supply was responsible, there would need to be special investigation made. One would have to find out where the typhoid bacilli came in, and how it was most likely that the typhoid bacilli got there, and just what the source was. That would require special study.

Q. Now did you have any information as to the source of the infection of the water in the lake?

11624 A. We had at that time, but I cannot recall the details of it. I remember it was all discussed at the time.

Q. How long have you been acquainted with that particular water supply,—that paticular lake?

A. Well I am not well acquainted with it, as I told you, personally. Of course I have heard of it.

Q. Well, you are personally acquainted with the district supplied by the lake?

A. Yes.

Q. And have been for how long a time?

A. Since twelve years ago.

Q. Now then during the entire twelve years, have they been able to determine the source of the infection of the water in the lake each year, and trace it on down from year to year and from time to time?

A. You mean the exact source?

Q. Yes?

A. I cannot tell you the details of that either; I don't know I have no doubt I could find out.

Q. Did you make any bacteriological analyses of the water of that lake?

11625 A. I never did, no. I should hope little from such an examination so far as typhoid bacillus is concerned. It would be extremely difficult to demonstrate.

Q. Would you not expect very little, of any bacterial analyses so far as the actual discovery of pathogenic bacteria is concerned?

A. I should be much more influenced by the biological test, as represented by the number of cases that occurred in the distribution of the water supply, than by an analysis, though much light can be thrown upon the qualities of a drinking water by the number of bacilli present.

Q. You think the number of the bacilli present is of any particular importance in and of itself?

A. Not considered alone, no. It must be considered along with all the other conditions.

Q. What are those conditions?

A. Well, the way the water is taken, the way the test is made, the chemical condition of the water, at the same time, the possibilities of explanation of the number from contaminations other than sewage contamination; the character of the bacilli or the character of the bacteria present. All would be factors that would have to be considered in a given case.

Q. What do you mean by the character of the bacilli?

A. Well, if I found or if anyone found a large number of 11626 bacilli of the colon group for example, that would be evidence,—other things being equal—of probable sewage contamination.

Q. Now doctor, getting back to conditions at Baltimore, this particular district supplied by lake Roland, is the only district in Baltimore that is affected annually, is it?

A. No indeed; I think; I don't recall the details of the different parts of the city today, I couldn't tell you about it. My opinion is that all water supplies of Baltimore are infected, but that some parts are more infected than others, but I cannot tell you which one was the most infected.

Q. Now doctor do you know the source of the water supply in that lake, Lake Roland?

A. No.

Q. Take the rivers around it, or anything of that kind, that empty into the lake?

A. I cannot tell you.

Q. Have you ever rowed over the lake?

A. No, I have been on its edge.

Q. How large a body of water did it appear to you to be?

A. My visual memory is not good enough to—

Q. Well, approximate it, as you best remember it?

A. I am afraid it would not be worth while, giving you a statement.

11627 Q. A body of comparatively still water?

A. Yes, not a large lake.

Q. Now from what other sources does Baltimore get its water supply?

A. Well, as I recall it, there is Gunpowder River—isn't there a Gunpowder river there? I don't know.

Q. How large a river is it?

A. I don't know at all; my opinion there is not valuable to you.

Q. Have you been on this river?

A. No.

Q. You don't know then whether there is any visible source of pollution on the banks of the river or not?

A. Not from my personal observation.

Q. You don't know whether there was on the lake or not?

A. No, I have heard rumors of all sorts of things, and statements—no, nothing from personal observation.

Q. Now is there any other source of water supply for the City of Baltimore excepting this lake and river?

A. I don't know.

Q. Those are the only two sources that you have any knowledge upon?

11628 A. Yes.

Q. And with those you are not familiar with the physical facts?

A. No, it is a side of epidemiology that I was not specially—

Q. And all that you have studied is the nature and character of the typhoid cases which came under your observation?

A. And parts of the city that they came from.

Q. And the parts of the city of Baltimore that they came from?

A. Yes.

Q. Without reference to the character and conditions of the water supply?

A. Well, at that time we discussed that, but the details of it of course have escaped me now.

Q. Now what other experience have you had in the study of epidemics?

A. Epidemics of typhoid, or epidemics in general?

Q. Of typhoid?

A. I had while house officer in the Toronto general hospital a considerable experience with typhoid cases. There was a large epidemic that year, larger than usual.

Q. But you had nothing to do with the actual source of or cause of the epidemic?

11629 A. No.

Q. Your experience was confined solely to hospital work?

A. Yes, and the pathology after death.

Q. Now you know doctor, I suppose, that the source of this epidemic was attributed there to the water supply there, was it?

A. In Toronto?

Q. In Toronto?

A. Yes it was; it was supposed I believe it was definitely proven but I am not sure, that there was a leak in the intake pipe. The pipe went out to an island, it passed through Toronto Bay, and they found out afterwards that there was a hole in the pipe, going across the bay, and that the real sewage mixed water was taken directly into the water supply of the city.

Q. How large is that bay, how wide?

A. Toronto Bay?

Q. Yes?

A. I should think it was about—again my knowledge of distances is very vague. I should think three-quarters of a mile across from the city to the island.

Q. Now was there any current along down the bay?

A. The water is tolerably stagnant there I imagine.

11630 Q. But there is a small creek or river or something of that kind going in from the land running out from the bay, into the lake?

A. The Don, but it is rather a small stream and a rather slow stream.

Q. And that would carry some current, would it not?

A. How much I don't know.

Q. It would be very small?

A. I should think rather small.

Q. Now where is that bay located with reference to the city of Toronto?

A. The city is directly on the lake front, I should think it extended a mile along the lake front.

Q. Is all the sewage of Toronto discharged into the Bay?

A. Whether it is now or not I don't know, as I recall it it was then.

Q. Now with reference to this water main that passed across the bay where was the sewage discharged, above or below?

A. How do you mean, above or below—I think on both sides.

Q. On both sides?

A. I think so; I think it ran right across the bay, and sewage was being poured out at various places along the lake front, for a mile as I recall it.

Q. Now do you remember what particular place in this
11631 water main it was broken?

A. No, I do not.

Q. How far it was from shore?

A. No, I haven't any information about that.

Q. It may have been a considerable distance?

A. From the shore?

Q. Yes.

A. Yes, I think it might have been anywhere in the bay, for all that I know; I don't know about it.

Q. And you say the bay is about three-quarters of a mile wide?

A. I should think so; it may be twice as broad; it may be less broad, but not more than twice.

Q. Do you know how deep the water is in the bay?

A. No, but it is deep enough for quite large steamers to come in.

Q. Do you know doctor, whether or not—or don't you know it to be a fact that they are now considering methods for disposing of or treating their sewage at Toronto?

A. I don't know.

Q. You don't know?

A. I hope they are; I don't know.

Q. Why do you hope they are?

11632 A. Because I think it is a pity for them to drink a polluted water supply when it might be possible by educating the people. and getting proper methods, to avoid the death rate from typhoid.

Q. Well, how far from the city does Toronto get its water supply?

A. That I don't know.

Q. How far did it at that time?

A. I don't know that.

Q. Do you know the typhoid death rate?

A. In the city of Toronto?

Q. Yes.

A. No.

Q. Do you know how far out they would have to go—

A. In Toronto?

Q. Yes, to get good water?

A. I do not, I am afraid.

Q. As an epidemiologist, what would be your judgment?

A. For them to get good water?

Q. To get good water that you would consider reasonably safe?

11633 A. How far out in the lake you mean?

Q. How far out in the lake in front of the city?

A. Oh, well, I cannot say off-hand, to get it absolutely pure and free from typhoid bacilli, they ought to go some distance of course.

Q. Well, about what distance would you say?

A. But even then a passing ship might pollute it temporarily. I don't think that they could be absolutely sure of excluding typhoid anywhere in the lake when ships are passing all the time.

Q. Well, aside from the ships?

A. But you cannot go aside from the ships because they are always there.

Q. Well, we will now assume that the ships and shipping interests are eliminated from the lake at Toronto, how far in your judgment would it be necessary for that city to extend its water mains into the lake in order to get a good water supply and free from sewage pollution?

A. Well, I should think that they would have to be absolutely sure of it, or to be tolerably sure, by assuming this impossible condition, that you suggest, that they ought to go out about one hundred miles.

Q. About a hundred miles?

11634 A. Yes, but that would be past the middle of the lake wouldn't it? I don't know how broad the lake is.

Q. Now what would be your object doctor in extending the water mains out into the lake?

A. One hundred miles?

Q. Any distance?

A. Well, it would be to diminish the amount of pollution of the water.

Q. Pollution from where?

A. From the sewage of the city.

Q. Of the city front?

A. Especially of that.

Q. Do you know how large Toronto is?

A. I think about 200,000 inhabitants.

Q. About 200,000?

A. I should think so.

Q. Now Toronto is situated on the breast of the lake, is it not?

A. Yes, right on the edge of the lake. Toronto bay comes
in a little but it is not a deep indentation. The island is prac-
tically the shore line. Do not understand me to say that I would
recommend putting a pipe out 100 miles. There is a much easier
way of getting a water supply than that, but if you tried
11635 to get it in that way, assuming an impossible condition,
that would be the purest water that you could get, I
should say, into the middle of the lake, farthest from the shore
would be the place to draw your water in case you had to get it
from the lake.

Q. The question though, doctor, was with reference to obtaining a reasonably safe water supply, a good water supply?

A. The best method of doing it?

Q. Yes, that is, how far it would be necessary to extend the mains into the lake to get a good water supply?

A. It would be much better to put in a sand filtration, and then take it from anywhere, provided you could educate the people there to conduct such a filtration plant in the proper way.

Q. Your idea however, is that the water would be polluted from the sewage of the city for quite a considerable distance?

A. I think it would undoubtedly be polluted for quite a distance out if typhoid fever were occurring in the city.

Q. And that was your object in saying that you would extend the main 100 miles out?

A. I say I would extend it to get the purest water, to the middle of the lake, which of course is not practicable.

Q. In other words then you mean that the pollution and
11636 polluting matter would pass from the city to the center of the lake?

A. Certainly the chemical polluting matter would.

Q. And how about the bacteriological?

A. I don't know how broad the lake is. I should think very few bacteria would pass directly out to the middle of the lake.

Q. If the chemical properties of sewage will pass doctor, why will not the bacterial properties also pass and is it not a fact that the chemical properties are largely made up of the bacterial qualities?

A. I think not.

Q. You think not?

A. Yes. The main difference of course, is that the chemical substances that I refer to are in solution, while the bacteria are in suspension, a totally different proposition.

Q. But the chemical analysis always takes into consideration totals in suspension and solution, do they not?

A. Yes sir.

Q. Do they pass through in filtration?

A. It all depends on the kind of filter one uses of course.

Q. Then the chemical analyses are of very little assistance, aren't they?

11637 A. Well, they are helpful. There are certain special substances that are very interesting.

Q. Well, if all these smaller bacteria pass through the filter, will not the small disease producing germs pass through the filter sheets as well?

A. You mean into the fluid?

Q. Into the fluid yes, and not be found either in suspension or solution?

A. I don't quite get your trend. If they pass through they must be there in suspension or solution.

Q. (Previous question repeated).

A. It depended on the kind of filter used.

Q. Well, won't these small bacteria whether they be pathogenic or non-pathogenic, appear somewhere in the chemical analysis, won't they have an effect upon the chemical result, or upon the result of the chemical analysis of the water?

A. Yes, but not a disturbing effect.

Q. What do you mean by a disturbing effect?

A. I mean by it this: that in the chemical analysis of water certain chemical substances are bad often, but particularly for instance the amount of chlorine, the amount of ammonia and so on. The bacteria would play a very little part in the 11638 amount of chlorine, for example.

Q. Yes, but don't bacteria play a very important part in the amount of ammonia, either free or albuminoid ammonia?

A. Yes.

Q. They play a very important part, don't they?

A. Yes, I think so, in certain factors, chemical analysis, they would; in certain other factors they would not.

Q. Then if they do play an important part, doctor, in the chemical analyses, why do you say that the chemical properties or constituents would pass from the sewers of Toronto out into the lake for a considerable distance, for instance, 100 miles, while the bacterial properties will not?

A. Because the bacteria would largely be destroyed before they went out there, and their chemical equivalents might pass out.

Q. You say largely destroyed?

A. Yes, possibly altogether destroyed before passing that distance, it would be difficult to prove.

GENERAL CROW: Difficult to prove their destruction?

A. Yes, there are bacteria out there, but it would be very difficult to determine the exact origin of the bacteria that are there; they might have come from passing ships.

MR. JEFFRIES: Then doctor, assuming that they do disappear and that they are the cause of the water-borne 11639 diseases, such as typhoid fever, and other like diseases, why would it be necessary to pay any attention to the chemical constituents and therefore why necessary to extend the mains so far out?

A. It would not be necessary to extend them further than there are pathogenic bacteria, but it might be difficult to determine just how far.

Q. And for that reason you recommend the extension as far as the chemical constituents can be traced?

A. I think I said that I would not recommend such an extension at all, because I don't think it is the easy way to get good water, but if you wanted to get a pure water,—as pure a water as possible in this way, by extending the mains, of course the further you go from the source of pollution, the safer you are.

Q. Now is it possible to determine whether or not the pathogenic germs or bacteria have disappeared?

A. Yes.

Q. In that distance?

A. It would be possible by giving a great many thousand people who hadn't had typhoid fever, that water to drink, and making them drink it, and if a lot of them developed the fever, and other sources of typhoid were excluded, that would
11640 prove that it was.

Q. And that is the only way that it can be determined?

A. You could be pretty sure probably, but that would be the safest test.

Q. But if I understand you correctly doctor, you take the position that it would be necessary in your judgment, to extend the mains so far as you could trace the chemical impurities because of the likelihood of the bacteria being present?

A. No, I do not intend to leave that impression at all, because chemical impurities will go wherever the water goes, being in solution; they can go ultimately a thousand miles.

Q. Do you know that the bacteria won't go a thousand miles?

A. All the evidence is against it.

Q. What is the evidence with reference to the longevity of pathogenic germs, doctor?

A. Well, I should refer you to the quickest way to get at the evidence,—to Baumgarten's Jahreskricht.

Q. Have you ever had any experience with the longevity of the typhoid germs in water?

A. I have worked with the typhoid bacillus. I made no special experiments dealing with longevity, no, but I have

worked the typhoid bacillus, and had it die out on me in
11641 media.

Q. Because of some inattention or something of that kind?

A. No, probably through exhaustion of the food supply.

Q. Or by extreme heat?

A. No, they were not submitted to too much heat.

Q. State doctor, your experience with reference to the life history of the typhoid bacillus in the laboratory?

A. Well, do you wish me to tell you how I have seen it behave on culture media, what it does? That is part of the life history of course.

Q. No, I want you to state brefly the experience that you have had studying the character of the typhoid bacilli with reference to the longevity of the typhoid bacillus in water, in the laboratory?

A. Oh, I told you that I had not worked especially on the longevity of the typhoid bacillus in the laboratory.

Q. Then so far as you know it maye live three weeks, and it may live ten weeks?

A. From my own personal researches?

Q. From your own personal researches?

A. One has to limit his own personal researches in the field.

Q. So that when you speak of the longevity of the typhoid
germs, and when you apply their longevity to the water
11642 of the Illinois river, you borrow the experience of other
men and do not speak from actual personal experience of
your own?

A. Entirely, yes, I am very glad to acknowledge that, as everything else that I have not worked on myself.

Q. Now doctor, you have stated, have you all that you know about conditions that existed at Toronto while you were there?

A. By no means.

Q. How is that?

A. By no means. I am afraid it would take a long time to state all that I know about that.

Q. With reference to the physicial facts surrounding Toronto and the water supply?

A. Yes, the general facts.

Q. The remainder that you may know, or if you know anything else, it was confined to the hospital?

A. To the that particular case, yes.

Q. Now then, doctor, state what other epidemics of typhoid you have studied?

A. In a clinical and pathological way, or in seeking the source of the water supply?

Q. In any way?

11643 A. Well, practically the only other typhoid epidemic that I have worked in is the one in Manila.

Q. In Manila?

A. Yes, in the Philippine Islands, but my attention there was directed entirely to the clinical and pathological side.

Q. You mean—

A. I didn't seek the source outside.

Q. That was in the laboratory?

A. That was in the laboratory and the hospital.

Q. And your attention and work there were directed entirely to the treatment of the disease?

A. No indeed; largely to the diagnosis, the symptomology, the clinical history and course, and the post mortem appearance.

Q. Now then, doctor, explain just exactly as near as you can what you mean by the various terms that you have used in your work at Manila, and the object that you had in making whatever determinations were made?

A. In Manila?

Q. Yes?

A. My object in the study of typhoid there was not to add anything new to our knowledge of the disease, unless it turned up in the routine. My object in studying typhoid at that 11644 time there was to set a high order of routine up at the beginning of the American medical work in the Philippines. Our work with malaria and dysentery and beri beri was the more original work that we undertook there.

Q. GENERAL CROW: You have not defined those terms yet.

A. Well the diagnosis means differentiating the disease from other disease, that might be confounded with it. By symptomology I mean the symptoms presented by the individual suffering by the disease, by the clinical course of the disease. I mean studying the changes from day to day in the symptoms, and comparing them with known descriptions of the disease, and other appearances of the disease taught by post-mortem. I mean growth and microscopic appearance of the organisms in the individuals dead of the disease.

MR. JEFFRIES: Now you didn't study the source of this epidemic at Manila?

A. No, it really was not interesting to us; it wasn't a profitable thing to study at the time.

Q. You didn't go there for that purpose?

A. No.

Q. Then doctor, I understand you that you have not studied the source of the epidemics in any case except in a casual way, as you have stated?

11645 A. Not typhoid.

Q. In typhoid?

A. That is quite true in plague and epidemics of cerebral spinal meningitis, and in beri beri. We tried very hard to ascertain the origin and mode of spread.

Q. And you have not?

A. But I am familiar with a large part of the work that has been done along those lines, and have to be, as a clinician has to be, familiar with the mode of the spread, to be a scientific clincian.

Q. But you obtained that simply by reading the publications of men who have studied it?

A. As every other scientific man does, yes.

Q. Including the literature on the longevity of typhoid germs?

A. Yes, I have read the literature of them.

Q. Was it necessary to read that as well as other things?

A. Yes, but not absolutely necessary to remember it or to read it,—unless you happen to be interested in it at the time.

Q. And you have not studied the longevity of the typhoid germ yourself?

A. I have studied it to a certain extent, but I have not
11646 made a specialty of it.

Q. You have studied it only as you have read about it?

A. No; I have studied it as I grew it in the laboratory in nutrient media.

Q. I understood you to say that you had made no studies as to its longevity?

A. I have not carried on a series of special researches, dealing with the longevity alone, but in my general work with the typhoid bacillus I have gotten certain first hand ideas about the way the typhoid bacillus will live, the length of time and in different media, and so on.

Q. In any water?

A. Yes, I have done it in distilled water.

Q. Have you ever tried it in the river water?

A. Sewage polluted water, no.

Q. How long did it live in distilled water?

A. I don't know; I couldn't tell you.

Q. You can't tell because you don't remember; is that it?

A. Yes, I don't remember.

Q. Well do you know how long it will live in distilled water?

A. No.

Q. Do you know how long it will live in river water?

11647 A. It will vary in river water according to the conditions under which it is—

Q. Do you know that from your own experience?

A. No, from reading.

Q. What particular portion of the literature did you take into consideration when you expressed an opinion that typhoid germs would live only from five to seven days?

A. In river water?

Q. Yes?

A. I took into consideration particularly the work that has been done upon the purification of streams in Germany.

Q. In Germany?

A. Yes sir.

Q. What was that investigation in Germany that was made?

A. Well it is some time since I have looked over the literature, but I could recall perhaps some of the publications that have been made on the subject. One of the earliest and one of the most interesting publications was that of Frank, who studied the water of the river Spree in connection with the water supply of Berlin.

GENERAL CROW: Give the date of that if you can.

A. I think it was before 1890. The same water supply
77648 was studied later by other investigators, and in a large
part the work of Frank was confirmed. Then the study of the waters from Paris to Rouen was another investigation that was made; the study of the Izar river in connection with the city of Munich was one of the important studies; also that was made of the studies of the water at Cologne,—are very important studies in connection with the purification of streams. I mean the water from the river Rhine between Cologne and Dusseldorf.

Q. Now doctor, don't you know that you are now giving the results that were obtained from an examination of the river Seine, and other rivers in Europe in reference to the determination of what they then characterized as the zone of bacterial purification, without reference to the appearance or disappearance of disease producing germs?

A. The studies dealt particularly with the number of bacteria.

Q. And not with reference to the life of the typhoid germ?

A. Without particular reference to the life of the typhoid germ, yes and with reference to the life of bacteria in general above and below.

Q. But have you ever made any study of any literature
that dealt exclusively with the life of the typhoid fever
11649 germ in river water?

A. No, no special study of that.

Q. Then doctor, not having made an examination or a study either of the literature, or from practical experience, of the life of the typhoid fever germ in river water, how can you express an opinion and confine your opinion as to the life of the typhoid fever germs to from five to seven days in river water?

A. For two very good reasons. One, that I have read of the life of bacteria, many of which are more resistant than the typhoid bacilli, to environmental destructive influences, and the other that I have taught with eminent men and bacteriologists in whom I have confidence, who have worked directly upon this problem, and they have given me the results of their experience, in conversations.

Q. So you mean to express an opinion that is neither based upon a study of the literature, and all writings of men who have made it a study, nor based upon practical experience, but based solely upon what people have told you with reference to it?

A. I do, and I am very glad to do it, because I don't think I could give you a more reliable source.

Q. Now then, doctor, state who told you how long typhoid 11650 fever germs would live in river water?

A. Among others, Dr. Jordan of the University of Chicago.

Q. Did Dr. Jordan tell you that he had been able to preserve the life of the typhoid fever germ in Lake Michigan water for ninety days.

A. I don't recall that he did.

Q. When did you talk to Dr. Jordan about it?

A. Off and on during the last three years.

Q. Since the opening of the Chicago drainage canal?

A. Yes.

Q. Who else did you talk to doctor?

A. Dr. Hektoen.

Q. From where?

A. Also professor of pathology in the University of Chicago.

Q. When did you talk to him?

A. I have talked with him at various times; also during the last three years.

Q. Do you know whether this Dr. Hektoen had any practical experince?

A. I don't know; he has worked a great deal with all kinds of bacteria.

Q. But you don't know as to whether he has had any practical experience of his own with reference to the life of 11651 the typhoid in the river water?

A. No.

Q. Anybody else that you talked to?

A. No, I don't recall any one, especially.

Q. Then you have derived your information from these two men?

A. No, I can give you another source of information; my own opinion derived from the literature dealing with the effects of river water upon bacteria in general, and the inference that I drew from that with regard to the typhoid bacillus.

Q. Doctor, your experience in analyzing river water—

A. I have no experience in analyzing river water.

Q. You have no experience?

A. No.

Q. The literature that you have read upon the subject and all the literature that there is upon the subject so far as you know, has reference simply to the appearance and disappearance of the numbers or counts of bacteria per cubic centimeter, or in a known quantity of water, did it, without reference—

A. I didn't say it—

Q. I am saying it. Without reference to the character
11652 and kind of the bacteria that are present?

A. No, I know that there are articles dealing with the life of special bacteria.

Q. As found in the running stream?

A. As found in running streams.

Q. State some of those doctor?

A. I could not.

Q. You know of no article that you could recall to memory now?

A. I do not; I could easily get them for you.

Q. Now isn't it a fact that there is no publication dealing with that fact, undertaking to give the exact longevity of disease producing bacteria in running water, because they cannot produce in the laboratory like conditions that exist in the water?

A. Oh, that is perfectly true; I thought you said river water.

Q. Well, river water, then?

A. Well life in water in water from natural sources has been studied.

Q. And studied in the laboratory?

A. And studied in the laboratory.

Q. Now doctor, I want you to give us one?

11653 A. I cannot give you a single article.

Q. Can you name us one?

A. No, but I could look it up for you.

Q. We can look it up ourselves.

A. I have an index memory, and the older I get the more it has to be an index memory.

Q. Do you class yourself as a pathologist?

A. In the sense in which the term has been used in this examination today, I do.

Q. Do you mean to class yourself as an epidemiologist when you say that the typhoid fever germs will live in the Missouri, the Mississippi, and the Illinois river only from five to seven days?

A. I do not say that. I didn't say that they had lived in those rivers only from five to seven days.

Q. How long did you say that they would live?

A. I didn't say how long they would live.

Q. How long will they live?

A. I do not know, nor is there any way at present of finding out.

Q. Then if they are once deposited in the water, is there any way of determining when they will disappear?

11654 A. In a river water that is being contaminated along the banks with other typhoid bacilli—

Q. After they are deposited in a given stream of water, is there any way of determining when those particular disease-producing germs will disappear from that water?

A. It would all depend upon the conditions of the individual stream. As a rule it would not be possible. You might make certain probable statements.

Q. Doctor, in view of what you have said that it would depend upon the condition of the stream—

A. And its banks of course.

Q. Yes. I will ask you how you can say that it would depend upon the condition of the water in the stream when you have never made an examination as to the longevity of the typhoid fever germ in water or in river water, or in running water, when you are unable to give but the names of two men who have ever given you any information upon that subject, when you have not studied the source of the epidemics about which you have testified, and the pollution of the water, or the infection of the water?

A. Well my answer would be that one gets, after years of work with bacteria and disease, and after years of perusal of the literature, a capacity for passing judgment upon
11655 literature and experiments, and opinions, that does permit him to come to a conclusion just as satisfactory as anyone can get under the circumstances.

Q. From a study of the literature?

A. General literature of bacteriology and pathology.

Q. What experience have you had in studying the general literature of bacteriology, doctor?

A. Well—

Q. I want to ask you this question: If your study of the literature of bacteriology, has not been confined to the characteristics of the disease itself?

A. By no means.

Q. And not with reference to the life of the germ after it leaves the infected body and passes away?

A. By no means; indeed, in teaching, one has always to give his students the life history of each germ.

Q. Do you teach your students that typhoid fever germs will die in five to seven days?

A. I have not taught students bacteriology for some time now, but if I were teaching them now I would not teach them that they would die in five to seven days; I have not said so.

Q. Will they die in five to ten days?

A. I said that I thought that in all probability in sew-
11656 age they would largely die out before ten days.

GENERAL CROW: In pure sewage?

A. Or in a water strongly mixed with sewage, such as in the Chicago Drainage Canal.

MR. JEFFRIES: Well they didn't die out in the Chicago river prior to the opening of the canal, did they?

A. In five to seven days?

Q. They didn't die out in the river prior to the opening of the canal?

A. Why, great numbers of them died, of course.

Q. Well, did they die out?

A. All of them?

Q. Yes?

A. They were constantly being put in there every day.

Q. And the current was very slow and sluggish, wasn't it?

A. Yes, if the typhoid bacilli were to be deposited there—

Q. But the chances for them to get out to the Four Mile crib in Lake Michigan was very slim as to their chances of getting down the Illinois river now, weren't they?

A. How is that question again?

Q. Their opportunity for getting out to the Four Mile Crib at Chicago, was far less prior to the opening of the canal than their opportunity to get into the river Desplaines and the 11657 Illinois river now, wasn't it?

A. I don't know the exact conditions at that time; that was before I came to Chicago.

Q. Assuming, doctor, that the conditions in the Chicago river were such that the sewage of that city was discharged into the river, which had practically no current, remained in the river until it became a putrid mass, offensive to the smell and sight, and that it finally and gradually passed out into the lake and infected the water in the lake to a distance of four miles out; what would say as to the opportunity for the destruction of the typhoid germs in the Cihcago river, and in the lake as compared with their destruction in the canal today,—the drainage canal today, and the Illinois river?

MR. TODD: I object to the question on the ground that it assumes a condition that did not and never did exist in regard to the Chicago river, and that is that all the sewage of Chicago emptied into the Chicago river, and it was the Chicago river sewage that contaminates the water four miles from shore, for the reason that other sewers of the city empty into the lake directly and not through the Chicago river.

MR. JEFFRIES: Go ahead and answer the question doctor.

A. May I have the question again?

Q. (Question repeated).

11658 MR. TODD: And in addition, the question assumes a fact to exist which did not exist except during times of freshets when the current in the Chicago river tended towards the lake, and when as a matter of fact in times when there were no freshets the Bridgeport pumping works operating as they did, kept the current from going into the lake.

A. My answer would be that if it remained a long time in the river without going out into the lake, without any movement whatever, it would soon die out, and I should think would die out just about as quickly as in the drainage canal, provided there was no access of new typhoid bacilli daily or at intervals, to it.

GENERAL CROW: You didn't answer that question. Read the question.

Q. (Question read).

A. My answer to that would be that you have two things in your assumption which are incompatible as I understand it. You say that the bacteria remain in the river without current, until they are a putrid mass, then you further assume that they go out and infect the lake with typhoid infection. I do not think they would.

GENERAL CROW: We will say the sewage remained, 11659 instead of the bacteria.

A. The assumptions seem to me to be incompatible.

MR. JEFFRIES: Well, doctor, wouldn't they pass further down the running stream before they would perish than they would pass into the lake before they would perish?

MR. TODD: You mean since the opening of the canal?

MR. JEFFRIES: I mean any stream.

Q. Would they not pass farther down the drainage canal, the Desplaines and the Illinois rivers, before they perished, than they would pass into lake Michigan before they would perish?

A. You mean distances?

Q. Distances, yes?

A. Or time?

Q. I am talking about distance now?

A. Evidence is in favor of the view that the greater the dilution with pure water, the longer the life of the typhoid bacillus, and the greater the mixture of sewage, the greater the percentage of sewage, the greater the number of saprophytic bacteria present the quicker the typhoid bacillus dies out. Other thing being equal.

Q. Then doctor going back to the other question—

A. Other things being equal.

11660 Q. Then doctor, with the addition of 250,000 cubic feet of water per minute into the canal, passing through the canal, the river Desplaines and the Illinois river, would have a tendency to prolong the life of the typhoid germ would it not?

A. I think so.

Q. And as the water is added, the life is continually prolonged,—the life limit?

A. While the dilution, as I understand it—

Q. Well, we are talking about the life, doctor; we are not on dilution now.

A. I was about to say that this refers to the life of the bacillus as I understand it, the dilution is not great enough to interfere with the killing off of typhoid bacilli by the saprophytic bacteria.

GENERAL CROW: That is not answering the question. Just answer the question as he asked it, please.

A. Read that question please.

(Question read)

A. Over its life in pure sewage, yes.

Q. And over its life at this time in the canal?

A. Yes, I think that it wouldn't die out quite so quickly but that it probably would not make a very great difference.

11661 Q. Then the greater the pollution the less time they live, is that it? The greater the pollution the less the life limit?

A. With saprophytic bacteria.

Q. We are speaking now of disease producing bacteria, typhoid germs, for instance.

A. In the presence of sewage, yes, other things being equal.

Q. The greater the sewage pollution the less the life limit of the typhoid germs?

A. Other things being equal in my opinion, that is true.

Q. Then the greater the sewage pollution in the Chicago river, prior to the opening of the canal, the less chance for the disease producing bacteria to live?

A. For a long time, yes.

Q. How long, doctor will typhoid germs live in typhoid feces?

A. I do not know.

Q. Don't you know that they will live for several months?

A. I do not know; I have never made the experiment. I know of reports in literature of the typhoid bacilli having lived much longer time in the body of human individuals, but there has always been a question as to the interpretation of the observations of the reporters.

11662 Q. As a biologist and bacteriologist, and pathologist of the disease of typhoid fever do you mean to say that you have never undertaken the study of the life or the longevity of the typhoid germ in the typhoid feces?

A. That is quite true.

Q. Now to what extent in literature does your knowledge go?

A. About that particular point?

Q. Yes?

A. I have no recollection of the statements in the literature. If I wanted to find out, I should just refer to my library and see what had been done on it. I never have been interested in working it out myself.

Q. Now doctor, if the greater the sewage pollution the quicker the destruction of the typhoid germs, why is it necessary to divert the sewage of Chicago from the Chicago river and the lake front in order to protect the water supply of the city of Chicago?

A. For the reason that every source of pollution should be removed as quickly as possible—every source of pollution of a water supply should be removed as quickly as possible.

GENERAL CROW: That is the only reason for it, isn't it?

A. And the nuisance of course.

11663 Q. That is all, is it?

A. The only reason for—please read that question again.

Q. (Question read).

A. Yes, as far as I can say, that is the only reason.

MR. JEFFRIES: Then doctor, would it not have been better yet to have turned the sewage right into the lake than to have run the lake water into the canal? In other words, wouldn't the dilution have been greater?

A. But the water that runs into the canal does not go into the drinking water, whereas, if it were turned into the lake it would run down towards the drinking water; isn't that a great difference?

Q. Is that all the difference that you want to make?

A. It seems to me the important difference.

Q. How is that?

A. That seems to me the important difference.

Q. Then doctor, would it not have been better for the people living below, for Chicago to have discharged their sewage into the lake or have turned the Chicago river into the Illinois river without the lake water, than to have mixed the lake water with it?

A. I think that if there were—if down within fifty miles they were drawing their water supply from that river, it 11664 certainly would have been reprehensible to have turned the sewage into the river—drawing their water supply unfiltered from the river.

Q. Doctor would it not have been better for the destruction of the typhoid fever germs to have turned the sewage of Chicago into the river Desplaines and thence into the Illinois river without mixing it with the water from Lake Mchigan, than to have mixed it with the water of Lake Michigan as they have; would it not have been better for the quality of the water in the Illinois river below the point of discharge?

MR. TODD: I object to the question on the ground that it is not proper cross-examination of this witness, and on the further ground that it does not touch upon any of the issues in this case as alleged in the bill of complaint filed herein.

A. My answer would be that I am sorry to say that I do not know enough about the engineering difficulties to know whether or not your alternative plan would have been a feasible one.

Q. Well, I will ask you this question, doctor: would not the disease producing germs, typhoid germs for instance, disappear much more rapidly if the sewage of Chicago was turned into
the drainage canal unmixed with the water from Lake
11665 Michigan, than it will now as it is being mixed with the
water from Lake Michigan?

A. I should think that that was probably true.

Q. Well, isn't that true from what you have read about bacteria, and their behavior in sewage,—and from reading the literature?

A. Yes, in my opinion, it is true.

Q. Then from a sanitary standpoint, applied to the condition of the water in the Illinois river below the point of discharge of the Chicago sewage into that river, it would have been better to have eliminated the Lake Michigan water from the canal would it not?

A. Of course there are other—

MR. TODD: I object to the question unless the question of being better applies to Missouri and not to the towns in Illinois, for the reason that the issues in this case as defined by the bill, do not raise the question of the effect of the Chicago sewage upon the towns in Illinois, whether diluted or otherwise, because prior to the opening of the drainage canal the sewage of Chicago was pumped into the Illinois and Michigan canal in its crude state, but the issues apply to the effect of the sewage of Chicago upon the citizens of Missouri, and not upon the citizens of Illinois.

11666 A. With regard to the one sanitary feature of destruction of the typhoid bacillus, I should say Yes; with regard
to other sanitary features of the river, I should not say Yes.

Q. MR. JEFFRIES: Doctor, I want to ask you this question, if it is not a fact that the discharge of 250,000 cubic feet of Lake water per minute through the canal, passing on down the Illinois river, has had a tendency to prolong the life of the disease producing germs that are deposited in the Illinois river; not only in the sewage of Chicago, but in the sewage of all other towns and cities situated upon the banks of the Illinois river, over and above what it would be, and what it was prior to the opening of the canal, when the 250,000 cubic feet per minute was not discharged into the canal?

A. I don't see how it would be possible to answer that question in the absence of examinations made before the water was put through.

Q. Doctor, in the laboratory you know what effect an added amount of water will have upon the bacterial contents of a certain amount of other water, don't you, in order to obtain information as to the longevity and appearance and disappearance of the saprophytic bacteria? Now applying that test to the waters of the Illinois river, I will ask you if the addition of 250,000 cubic feet of water per minute coming from 11667 Lake Michigan, through the canal into the Illinois, has not only had a tendency to prolong the life of the disease producing germs found and contained in the Chicago sewage, but also of the disease producing germs contained in the sewage of other cities—of every other city situated upon the banks, and drainage area of the Illinois river, and which is discharged into the Illinois river?

A. I can only repeat that it would be impossible for me—

Q. Answer my question, doctor.

MR. TODD: I submit that he is answering the question.

A. As it would be impossible for me to make a definite statement with regard to that in the absence of data concerning the conditions in the river before the opening of the drainage canal,—my opinion on the matter would not be worth anything without that data, because the conditions vary for each stream; the conditions vary so much that tests would have to be made.

Q. Then doctor if that be true and you cannot tell how is it possible for you to express an opinion as you did in your examination in chief, in answer to Mr. Todd's question, that the typhoid germs will not come, or will not pass the journey and survive from Chicago to St. Louis?

11668 A. My opinion is formed on the total mass of evidence there, but that is a very different proposition. The conditions are very different.

Q. What mass of evidence is your opinion formed on? Was not this very thing that we are talking about—does not that enter into—

A. That was one factor only.

Q. And that factor was eliminated was it not, the addition of the 250,000 cubic feet of water?

A. Was eliminated?

Q. Was eliminated?

A. How do you mean was eliminated?

Q. From your opinion, from the total mass of facts and circumstances and information upon which you base your opinion as to whether or not the typhoid germs would go down and survive the journey?

A. No, it wasn't at all.

Q. It was not a factor?

A. It was not eliminated.

Q. Then if it is not eliminated, doctor, why is it that you cannot state whether or not the addition of the water would have a tendency to prolong the life not only of the disease producing germs, that are contained and found in the sew-
11669 age of Chicago, but in the sewage of every other city along the Illinois river?

A. I have already said that I thought it did prolong the life immediately below Chicago, but I would not be prepared to make any statement with regard to the effect of that water down at St. Louis, or far down the Illinois river.

Q. Now if the added volume of water at Chicago will have an effect upon prolonging the life of the typhoid germ, why will not that added volume of water have a like effect upon all other germs that find their way into the Illinois river below Chicago?

A. I should like to think about that before offering an opinion on it.

Q. All right, go ahead.

A. I should think that would extend the percentage increase of pure water added at various points; it would increase the longevity of the typhoid bacillus correspondingly.

Q. I don't think you understand the question. I don't mean the addition of water by the tributaries of the river; I mean the addition of the 250,000 cubic feet of water per minute at Chicago.

A. Yes.

Q. Now then, if that additional volume of water will
11670 have the effect at Chicago of prolonging the life of the typhoid fever germ, will not that same added volume of water also prolong the longevity of the typhoid germ, that is discharged into the Illinois river, from all of the points below Chicago?

A. Now I do understand it. I think that it would, but in a progressively diminished manner, because the relative percentage of increase would grow progressively less owing to the contents of the tributaries coming in below.

Q. Now doctor, with no other discharges from the tributaries subsequent to the opening of the canal than there was prior to the opening of the canal, with the volume of the water flowing from the tributaries into the Illinois river, practically the same now as prior to the opening of the Chicago drainage canal, I will ask you if the discharge of the 250,000 cubic feet of water per minute through the canal not only prolongs the life of the typhoid fever germs contained in the sewage of Chicago and discharged into the canal, but also prolongs the life of the typhoid fever germs deposited and discharged into the Illinois river from all the towns and cities on the Illinois river below Chicago as well?

A. I think I understand that. As the evidence is that the life of the bacillus is not very much prolonged, even at
11671 Chicago, I should doubt that it would be measurable, of course far down the river, that the longevity would be measurable, if we could submit the thing to experiment, which we cannot do.

Q. You say if the evidence is that it is very much prolonged?

A. Yes.

Q. What do you mean by that?

A. At any rate the evidence is that it dies out more quickly under the present conditions.

Q. Have you made any examination?

A. No, but doctor Jordan has told me of his examinations.

Q. You are taking Dr. Jordan's word for it, and not your own?

A. Yes, again.

MR. JEFFRIES: We move to strike out everything that this witness obtained from Dr. Jordan.

Q. The increased volume of water must necessarily have a great effect upon the life of the germ, does it not, doctor?

A. It has an effect.

Q. It has a great effect, hasn't it?

A. I don't know the comparative statement before and after in this particular case, but I know in a general way that the longevity is increased by the addition of pure water to the sewage.

11672 Q. But you don't know as to the extent of the increase?

A. Similar work was done on the Zurich water, by Tiemann, in 1900, at high water and low water, and comparison was made there, but the exact details of that research I have not in my mind.

Q. Then doctor, in view of that I want to ask you this question again. Would it not have been better from a sanitary standpoint and for the sanitary condition of the water in the Illinois river, to have turned the water and sewage of Chicago from the Chicago river, as it originally existed, into the Illinois river, without any lake water, than to have turned the lake water and sewage at the rate of 250,000 cubic feet per minute through the canal into the river?

MR. TODD: I object to the question on the ground, first, that it is not proper cross-examination; second, that it does not concern any issue in this case as raised by the bill of complaint, in regard to the sewage of Chicago affecting the inhabitants of the State of Missouri. And another reason as to whether the turning of the sewage into the canal without lake water, and the ability to do that being an engineering proposition that does not in any way affect the questions at issue in this case, and for the further reason that the question does not state whether it was better for the citizens of Chicago or for the citizens

11673 along the Illinois valley, or the citizens of Missouri, and unless it is confined to the citizens of Missouri it is not a proper question.

MR. JEFFRIES: The question is confined to the sanitary condition of the water in the Illinois river.

A. Does originally existing mean—

MR. JEFFRIES: Prior to the opening of the canal?

A. Yes, with the pumping going on? Give me the question again please.

(Question read.)

A. My answer to that would be that it might have been better for the upper part of the river, but that I doubt if it makes any appreciable difference with the lower part of the river.

Q. Have you any reason why it would not make any difference in the lower part of the river?

A. For two reasons, that I think the stream would purify itself so thoroughly at the lower end of the river, that the pollution would be inappreciable; and the other reason that the increase in volume of water relatively, would be so slight in the lower part of the river, owing to the access of so many tributaries in between, that any increase in the longevity of pathogenic bacteria would be doubtful, immeasurable.

11674 Q. Doctor, do you take into consideration in your answer that the volume of water flowing down the Illinois river at Grafton during certain seasons of the year since the opening of the Chicago drainage canal is less than the total volume of water passing through the Chicago drainage canal?

MR. TODD: I object to the question if it is stated as a fact.

MR. JEFFRIES: It is stated as a fact and shown by Professor Palmer's charts.

GENERAL CROW: All the testimony shows that,—that less water passes through the Illinois river than comes through the canal now, in cubic feet.

MR. TODD: I don't recollect that, but I reserve my objection just the same. Since the opening of the canal when they are throwing 250,000 cubic feet at Lockport, there has been less than 250,000 cubic feet passing at Kampsville.

MR. JEFFRIES: Yes, and at Grafton.

(Question repeated).

A. Assuming the fact I should think that Grafton was so far below Chicago that it was a matter that had very little bearing upon the question.

MR. JEFFRIES: Why, because of the time, or because 11675 of the volume of water?

A. Because of the self-purification of the stream.

Q. And what makes that?

A. The lack of nutritive materials and the sedimentation.

Q. Now what causes the loss of the nutritive materials?

A. Saprophytic bacteria largely.

Q. And as the nutritive materials disappear the saprophytic bacteria disappear?

A. Yes, that is true.

Q. But do you know doctor, that the typhoid fever germs do not depend upon the nutritive material in any way for their life?

A. I know that they can live a long time without nutritive material.

Q. And don't you know that they live longer without nutritive material than they do with it, unless confined in their native stage in the human system?

A. I think I simply have no opinion to offer on that. I do not know enough about it to offer any opinion.

Q. Now it is your opinion, is it, that the sewage material kills it?

A. My opinion is that they die out quicker when there is a great deal of sewage than when there is not. That is 11676 rather different from the way you put it.

Q. Now do you think there is enough of that sewage goes down to Grafton to kill the typhoid germs?

A. Which typhoid germs?

Q. That are deposited in the water at Chicago—in the river at Chicago?

A. I am not sure that any typhoid germs get as far as Grafton from Chicago.

Q. Well, do you know that they do not?

A. I don't think that they do. I don't think anybody could say that they did not. My opinion is that they do not.

Q. Well now, on what do you base that opinion? You say they don't—your opinion is that they do not?

A. I do not say that they do not, because I don't think anybody can say that, but my opinion is that they do not.

Q. Now on what do you base your opinion that they do not?

A. On the way bacteria die out in river water.

Q. Now then, on that question you have reference to the manner in which bacteria in general die out, without reference to the kind or the character?

A. And the statements that have been made to me by bacteriologists regarding the death of the typhoid bacillus, itself.

11677 Q. Now then, doctor, what is it in the water that causes them to die out?

A. That causes typhoid bacilli to die out?

Q. Yes?

A. I believe myself that a great many different factors are concerned, and that probably the factors are very different in every two rivers; that it is not the same thing in one river that it is in another, and that there might be great differences in individual rivers. In my opinion sedimentation and oxidation processes together with the influence the saprophytic bacteria, and exhaustion of food supply are the most important factors.

Q. Doctor, did you ever make any experiments with reference to the effect of oxidation upon typhoid bacilli?

A. No.

Q. Don't you know as a fact that they do not oxidize?

A. Well, they would if they were dead or sedimented.

Q. If they were dead they would oxidize?

A. I have oxidized typhoid bacilli, yes, when they were dead.

Q. But as long as they can live oxidation has no effect on them, does it?

A. I don't know that that has ever been determined.

Q. Now isn't that the general opinion, that oxidation has no effect upon the typhoid germ unless life is extinct?

11678 No, I am sure it would have some effect.

Q. They live in the earth, don't they?

A. Yes, for a time.

Q. They live in the winter time, don't they?

A. Yes, they can live in ice.

Q. They live many months in the earth, don't they?

A. I don't think there is evidence in favor of that; I don't know of any evidence in favor of that.

Q. Have you never read any of that kind of literature?

A. I have never read that point, no. I know that they have been said to live in dust for as long as ten days.

Q. Haven't they been said to live in dust as long as thirty days?

A. I don't know.

Q. Did you ever read about the case there in Plymouth, Pennsylvania, where they laid there for months?

A. That was a winter case, and it was the spring floods that brought it down. Yes, that is all reported in the Pennsylvania State Reports.

Q. They lived in the earth there, didn't they?

A. I though it was on the surface of the earth.

Q. Well, that is the same.

A. Under the snow. I may be wrong; it is a long time
11679 since I have read it.

Q. How long did they live there under the snow?

A. I don't know the length of time.

Q. Four weeks?

A. I don't know at all, how long it was after they were deposited from the typhoid patient. It was one case of typhoid and if I recall—well, I don't know about one dejecta, but it was from one case anyway, that that whole epidemic of 1100 odd cases developed.

Q. Didn't they live six weeks there and longer?

A. I don't know at all.

Q. If they did live there six weeks, in the snow, couldn't they live six weeks under the ice in the Illinois river?

A. I should think the conditions under ice in the river would be very different than conditions under snow on the ground.

Q. You should think they would be?

A. I shouldn't like to say that the same thing would happen in the two instances.

Q. Do you mean to say that they would disappear as rapidly under the ice as they would during the summer season of the year without ice?

11680 A. I don't think they would disappear so fast in the winter, on account of the saprophytic growth.

Q. There would be a very radical difference, would there not?

A. I should think so.

Q. But you don't know?

A. It would be my opinion that there would be.

Q. What causes that saprophytic growth?

A. The presence of food stuffs suitable to saprophytic bacteria and the presence of enough bacteria to spread the growth.

Q. Now then, doctor, do you know—I will ask you this question, if you don't know that the saprophytic growth does not destroy the typhoid germ; that it simply overgrows it and has no effect upon its life other than what little toxin it might cast off, but that as you add additional volume of water to the stream they have a better opportunity to swim away from those toxins, and therefore better opportunity to live, and do live longer; isn't that true?

A. The evidence is that they die out in the presence of saprophytic bacteria. Just what the reason is, I don't know.

Q. Don't you know that there is no evidence showing that they do die out in the presence of saprophytic bacteria any sooner than they die out in ordinary river water, or drinking water?

11681 A. But ordinary river water and drinking water contains saprophytic bacteria.

Q. But not so many as sewage water?

A. Not so many, no.

Q. In other words, doctor, don't you know this, that they die out just as quickly in ordinary safe drinking water as they do in sewage polluted water, and that the difference in distinguishing the duration of life in the two experiments is caused by the great increase or growth in the saprophytic bacteria in the sewage polluted water, so it has a tendency to cause the saprophytes to overgrow and render the conditions such that you cannot discern the typhoid because of their failure to multiply?

A. Well, it is obvious that there could be two interpretations of the results of such experiments. One interpretation would be this; the other would be the one that I put upon it.

Q. Now isn't it a fact that scientists, or men reputed as scientists, in discussing that in the literature, have given that as the reason for the disappearance of the typhoid germ in the sewage polluted water, in making their analyses bacteriologically in the laboratory, that the typhoid does not disappear any more rapidly in that water than it would in the natural water, 11682 but that the saprophytes overgrow it so that they cannot discern it—they cannot discern or distinguish the typhoid. It is obscured but not destroyed?

A. Yes, I think both opinions are held. It is obvious that one could not say which was right when the doctors disagree.

Q. And it may be either?

A. Yes, although my opinion leads to the other view, that they do die out.

Q. What evidence have you that they do die out?

A. The evidence that .one cannot find them. I feel that we could find them if they had not died out.

Q. Isn't that true of all water, that you cannot find them?

A. I know of no cases of where it has definitely been present.

Q. Don't you know doctor, that they have not been found even in sewage?

A. That is what I say. I know of no case where they have been definitely demonstrated in water, but the biological test shows its presence.

Q. Now doctor, you say temperature would have something to do with their life?

A. I should think it might, yes.

Q. Do you believe, doctor, in the old doctrine of self-purification of streams?

11683 A. Well, if you will formulate the old doctrine I could give a better answer to that.

Q. The Pettenkofer theory for instance?

A. I don't know it under that name. I know who Pettenkofer was, but I don't know his formula of that theory. If you would give me the exact—

Q. Will running water in the absence of sewage pollution eliminate pathogenic bacteria?

A. Yes, it will. I think it will. The sedimentation leads to the disappearance of the pathogenic bacteria. I say I think, because it must be only think, because the conditions do not exist. There is no such condition as far as I know, of running water without saprophytic bacteria.

Q. Do you know that they die in the course of sedimentation?

A. I think all the evidence favors that view.

Q. What evidence do you have reference to?

A. The fact that typhoid—that we have great typhoid epidemics, and that they disappear and die out again, the stream does purify itself. We have typhoid epidemics even from pond waters, and they die out. If they didn't die out, and all the people who are susceptible had not been infected, then the typhoid bacilli would have caused so many more people to

11684 have the disease that it would not have died out.

Q. Then it would be most liable to produce bad results, low water or high water?

A. To produce which?

Q. Bad results from a sanitary standpoint?

A. You mean as regards sedimentation or as regards the influence of saprophytic bacteria? I don't quite see what you mean.

Q. I mean in the conveyance of typhoid fever germs?

A. Down a river?

Q. Yes.

A. Without regard to the swiftness of the current; simply the height of the water, the depth of the water?

Q. Well, a given stream, under the assumption that at high water the current is more rapid than it is in low water, taking into consideration all the conditions that naturally arise between high water and low water in a given stream?

A. The studies of Thomann of Zurich refer to that particular point. He studied the river at Zurich at high water and at low water, and as I recall it, his results went to show that there was less purification of the water in general from bacteria when the water was high than when it was low.

11685 Q. Then the more water you put in a stream the more dangerous it is?

A. Other things being equal I should say so.

Q. Then the more water you put in the canal at Chicago, the Chicago drainage canal, the greater the danger is increased below, down the Illinois river?

A. For a certain distance.

Q. If there is more water comes out of the river at Grafton than there was prior to the opening of the canal, wouldn't the danger be increased?

A. If it were due to the opening of the canal and there were a great increase in volume, I think there would be some increase.

Q. Well suppose it was doubled at certain seasons, as to what it was in like seasons of prior years?

MR. TODD: I object to the question for the reason that the doubling of the flow of the drainage canal does not carry with it the increase of sewage which is thrown into the water when it is increased.

Q. (Question repeated.)

A. Other things being equal, I think that the longevity of the bacteria would be increased.

Q. Now doctor, you say you don't know how long typhoid germs will live in river water?

11686 A. In ordinary river water or sewage contaminated river water?

Q. Well, either or both?

A. I don't know absolutley, no. I have an idea of about how long.

Q. Do you know, doctor, how far the effects of the sewage of Chicago can be discerned in the Illinois river?

A. You mean bacteriological or chemical or both?

Q. Both, yes?

A. In the absence of data before the opening of the canal I don't know what the effect has been definitely.

Q. You don't know whether the sewage of Chicago would have an appreciable effect upon the water in the Illinois river at Kampsville, or not?

A. You mean in the dangerous character of the water?

Q. Yes?

A. I should think it very improbable that it had any effect on the water at Kampsville.

Q. Now on what do you base that?

A. On the distance that Kampsville is from Chicago.

Q. You judge altogether by distance?

A. No, I judge also by the fact that there is so much sewage in the water just below Chicago that I think the water would be robbed of its dangers very quickly. 11687

Q. Is there as much water in the Illinois river below Chicago now as there was water in the lake front before the canal was opened?

A. You mean in volume?

Q. Yes?

A. And how far out on the lake front would you go.

Q. Or dilution.

A. At what point in the river?

Q. Whatever point you mentioned.

A. Kampsville?

Q. No you mentioned it would be much farther above that.

A. Well, just below—

Q. The imaginary point that you have in your mind, whereever that may be, that you claim purification has taken place, and the water has been robbed of the pathogenic germs. Now where is that point?

A. Well, that is a vague point. Of course we have no means of determining.

Q. Why is it vague?

A. Because our information is not definite enough to permit us to locate it.

11688 Q. Now we will take Henry for instance, you know where that is?

A. Henry is above Peoria, yes.

Q. Now are the dilution and the opportunities for dilution as great at Henry as they were in the waters at the lake front prior to the opening of the canal?

A. Why I should think that it would be purer at a place like Henry, but I don't know.

GENERAL CROW: No, that is not the question. Is there more or less water in proportion to the sewage?

MR. JEFFRIES: In other words, is the dilution greater at Henry than it was at the intakes in the lake at Chicago?

A. The percentage composition—that the percentage composition at Henry of sewage and water, is what you mean?

Q. Yes.

A. I am afraid that any opinion I could offer on that would be too vague to be of any service.

Q. What would be your judgment about it? You understand the physical circumstances—all the points that are necessary?

A. I should think that chemically the water at a place like Henry would look like a more contaminated water than the water out at the intake, but I don't know.

11689 Q. Do you believe that the water at Henry is purer bacterially?

A. Pure, free from bacteria?

Q. No, do you believe that it has less bacteria in it at Henry since the opening of the canal than the water in Lake Michigan had at the Four Mile crib prior to the opening of the canal?

A. I don't know anything about the sewage relations of LaSalle, Ottawa and Morris, if they are pouring sewage into the river above Henry, then I should think the water would be much more polluted.

Q. You know about the population of those towns, don't you?

A. I have the data here.

Q. You may add that to Chicago and see what the per cent would be?

A. The point would be—the places like LaSalle and Ottawa being close to Henry, would contaminate the water dreadfully, if they are close. I do not recall just how close they are, but I should think that LaSalle was within thirty or forty miles of Henry.

Q. What is your opinion as to the sanitary condition of the water at Henry above Peoria?

A. Well, it is relatively very good.

11690 Q. What do you mean by relatively?

A. Well, I mean as compared to the water at Lockport, or the water below Peoria.

Q. Is it fit to use for domestic purposes?

A. Not ideally domestic purposes; I think it ought to be boiled.

Q. Is it reasonably safe?

A. I should think it was as safe as the water perhaps at Kampsville or a little above Kampsville.

Q. Would you recommend the water in the Illinois river at Henry as an epidemiologist, for domestic purposes?

A. No, nor anywhere else in the Illinois river, nor in the Missouri river, nor in the Mississippi river.

Q. What in your opinion is the difference in the effect of, or would be the difference in the effect of the sewage of Chicago upon the water in the Illinois river at Henry now, as compared to what it would have been prior to the opening of the canal if the Chicago river alone, containing the sewage of Chicago, had been turned into the Illinois river instead of the present drainage canal, with the 250,000 cubic feet of water per minute?

A. I don't know the engineering situation, but I should doubt if there would be very much difference.

11691 I would not be surprised if there were a difference in the volume—some difference in the volume of water, but I would be surprised if there were much difference in the dangerous qualities of the water.

Q. Do you think, then, that a flow of 29 miles in the canal purifies the water in the canal of the sewage from Chicago?

A. Is it only 29 miles to Henry?

Q. No, the canal is 29 miles long.

A. I should think it certainly did not, but I do not know how many pathogenic bacteria would be present there without getting—

Q. Well, you are figuring now as an epidemiologist?

A. Yes.

Q. And considering Chicago sewage as you would consider the sewage of any other city of like population?

A. Yes.

Q. Now then, if it does not purify itself in a running of 29 miles, through the canal, would all the effects of the sewage be removed in ten miles distance from the mouth of the canal?

A. That would be 39 miles from Chicago. Would all of the sewage be removed?

Q. Yes.

A. I shouldn't think so.

11692 Q. Would all of the pathogenic germs be removed?

A. I don't know.

Q. Well, would you think they would?

A. I wouldn't like to trust the water at that distance.

Q. Well, at a distance of 49 miles would you say they are all removed?

A. I should think they might be if there were no new excess with water.

Q. You would be willing to trust the water, would you?

A. No, I would not be willing to trust the water at 150 miles, because I should avoid it under all circumstances, on account of other contamination on the way.

Q. Cutting out all other contamination, eliminating that, we are dealing now with the effects of Chicago sewage upon that water; would you be willing to recommend it for domestic purposes in its raw condition at a distance of sixty miles from Chicago?

A. I shouldn't recommend it without filtration, or any river water.

Q. Would you recommend it at 75 miles from Chicago?

A. I would not recommend it any distance from Chicago without filtration.

Q. Cutting out now all the sources of pollution other 11693 than Chicago?

A. Oh, but that is an impossible condition, isn't it?

Q. That is a supposition, and that is an assumption and I want the answer. Would you consider that the water—

A. I don't think there is any possible way of telling for sure.

Q. —Became free from all pathogenic germs?

A. In my opinion it would be, but I don't think one could be sure.

Q. Would you recommend it as an epidemiologist, 150 miles away from Chicago?

A. I should want to have a biological test made.

Q. In the absence now of any biological test, we are talking about the river itself, and your knowledge of epidemiology?

A. I think it would be safe.

Q. Would you recommend it?

A. No.

Q. Would you now recommend it at Grafton?

A. No, nor at New Orleans.

Q. Removing all sources of pollution other than Chicago, from the Illinois river, would you recommend, as an epidemiologist, the water in the Illinois river at Grafton, knowing 11694 that the sewage of 2,000,000 of people at Chicago had been discharged into that river by means of the drainage canal, would you recommend it in its raw condition, as an epidemiologist, and suitable for domestic purposes?

A. In the absence of all contamination on the way, I think it would be safe.

Q. Would you recommend it?

A. No.

Q. Would you recommend it at St. Louis?

A. No, though I think it would be safe.

Q. Well, if you think it would be safe why are you not willing to recommend it?

A. Because we have ways of making absolutely sure. My opinion on safely is an opinion. We have methods of being absolutely sure, about our drinking water.

Q. But your opinion is not of sufficient weight with yourself to justify you to recommend the use of that water without filtration?

A. Not when we have a method that makes us absolutely sure.

Q. Taking conditions now as they exist in this civilization, with the means of ascertaining bacterially, chemically and every other way, the sanitary condition of water, your opinion that it is safe is not sufficient to justify you in recommending its use for domestic and drinking purposes, in its raw condition at Grafton and at St. Louis? 11695

MR. TODD: I object to the question as I do not believe the witness has stated that with the biological test having been made that he wouldn't use it.

MR. JEFFRIES: Cut the biological test out.

Q. (Question repeated, eliminating the word "biologically.")

MR. TODD: I still object to the question because the witness has not said "any other way."

A. That is the exact point of course, if we could make the test bacteriologically, chemically and in every other way, then I would recommend it.

Q. Now then, in the absence of all those tests, and with your knowledge as an epidemiologist, assuming that all sources of pollution are removed from the Illinois river, save and except the sewage from Chicago, discharged into the canal, with the 250,000 cubic feet of water per minute; thence into the Illinois river, would you recommend the water of the Illinois river at Grafton for domestic and drinking purposes, and would you recommend the water at St. Louis at the chain of rocks as suitable for domestic and drinking purposes in the condition that it would be in in arriving at those places?

11696 A. In the absence of all tests.

MR. TODD: Do you mean whether or not at St. Louis, as it now exists?

GENERAL CROW: Oh no we are assuming now that the water comes down and goes into the intake.

A. And that there is no water comes into the intake. Is that the question?

Q. Yes.

A. You assume that in that event St. Louis gets no water except that that came from Chicago?

Q. Yes.

A. I would of course make tests in such a case, and I think it would be safe to recommend it.

GENERAL CROW: But without the test would you recommend it?

A. I don't think one would have the right to recommend any water without making a test.

Q. But with that specific proposition would you recommend that water?

A. That is included in my answer.

Q. Excuse me; that question is susceptible of an answer "yes" or "no."

MR. TODD: I submit that the witness has answered that question.

11697 MR. JEFFRIES: Well, he has passed judgment upon this water without making tests as I understand it; now this is a hypothetical question and we ask the witness to answer the hypothesis.

MR. TODD: I submit that the witness has answered the question.

GENERAL CROW: No, he says he would make tests, and that is what our question excluded.

MR. JEFFRIES: You have recommended water without making tests, have you not?

A. I have recommended it?

Q. Yes.

A. I don't know that I have.

Q. Have you not stated that the sewage of Chicago had no effect upon the water at Grafton?

A. I said that in my opinion it had not.

Q. And that statement was made without having made a test of that water?

A. But I didn't recommend its use. I said in my opinion it would have very little if any effect, but that is a very different thing from recommending its use.

Q. Now you say that you think the water would be safe under the hypothesis that was just propounded to you?

11698 A. In my opinion, it would be, but I should—

Q. Now is that opinion such that would enable you in your judgment to recommend the use of that water for drinking and domestic purposes?

A. Without making tests?

Q. Without making tests.

A. No.

Q. Now then, what character of tests would you make?

A. Probably the test would have been already made when my opinion was asked, by people having drank the water, and if typhoid existed among them, and there were no other opportunities for typhoid infection of those people, I should be very suspicious of the water.

Q. Is that the best test?

A. I think so, yes.

Q. The use of the water?

A. I think it is the best test in the long run.

Q. Now doesn't the sanitary condition of the water depend largely upon the flow, the volume, the rate, the temperature the condition of the river with reference to flood times and low water stages, winter seasons and summer seasons?

A. It depends upon all those things.

11699 Q. And isn't it absolutely impossible for anyone to determine the exact place in the river where the water can at all times be recommended for domestic and drinking purposes, after the water of that stream has once been polluted with sewage discharges?

A. My answer to that is that as the water is continually being contaminated at a great many different points, it is safe to recommend that it be not used at all without filtration.

Q. Doctor, is it not absolutely impossible to determine at all times of the year the exact place where you would recommend the water passing through the drainage canal, the Illinois river and the Mississppi river, that it would at all times be safe for domestic and drinking purposes?

A. My opinion is that it is never safe at any time for domestic purposes.

Q. Now what makes that opinion?

A. The fact that typhoid fever cases are occurring among the people who drink the water.

Q. What makes the water unsafe?

A. Typhoid bacilli in the water.

Q. And where does it come from as a rule?

A. From the excreta poured into the rivers all along the banks.

11700 Q. Into the sewers?

A. Into the sewage, yes.

Q. Then the more sewage deposited into a river or discharged into a river the more danger?

A. For the places within a certain distance below that point, yes.

Q. Now then, can you name those distances?

A. No.

Q. Can you place them?

A. No.

Q. On any stream?

A. I don't think so. I don't know how it is.

Q. Can you, doctor, determine the point of safety in the Illinois river, and the point where the sewage of Chicago has lost its effect upon the waters of the Illinois river so far as pathogenic germs are concerned?

A. Only in a probable way.

Q. Can you ascertain it in such a way as would enable you to form an opinion that would be reliable?

A. It can be ascertained in a way that would make an opinion very probably reliable.

Q. Would it be an opinion upon which you would be able to make a recommendation?

11701 A. Oh yes, I could make a recommendation.

Q. For the use of the water for domestic and drinking purposes?

A. I think I have answered that question before.

Q. Well I know, but I want you to answer it again. You didn't answer just exactly that as I understood the case to be.

A. I think that considering the state of the education of the people and the state of politics and the possibilities of sanitary engineering, and the introduction of filtration plants satisfactorily, and so on, in this country, one would be justified in recommending the use of the water at certain places.

Q. Can you locate any place on the Illinois river where you would recommend it?

A. Assuming that—

MR. TODD: Under the present conditions?

MR. JEFFRIES: Under the present conditions where the water of the Illinois river has freed itself from the sewage contamination of Chicago?

A. And assuming that it got no other contamination since, do you mean?

Q. Yes, that is really assumed, but I am taking conditions as they stand. At what point in the Illinois river 11702 in your opinion has the water of the Illinois river freed itself from the sewage of Chicago or from the dangerous disease-producing germs contained in the sewage discharged into that river at Chicago?

A. I should think that for instance to take a definite point at which it would be, I think, safe, a place like Averyville, above Peoria, would be very safe as far as the sewage of Chicago is concerned.

Q. Now then do you know how far Averyville is from Chicago?

A. I think it is about 150 miles perhaps.

Q. About 150 miles from Lockport?

A. It is 159 miles from Chicago.

Q. Do you know how long it takes water to go from Chicago down to Averyville?

A. I don't know exactly, no.

Q. Now doctor, I want to know if that wouldn't have something to do with it?

A. I would go more by the bacteriological analysis at that place.

Q. Now then I want to ask you this question; if you were called upon to pass upon the sanitary condition of the 11703 water in the Illinois river at Averyville, knowing that the sewage of Chicago had been turned in, regardless of the fact that sewage from other cities upon the water-shed above Averyville had also been turned in, and the fact that Chicago had discharged its sewage through the drainage canal into the Illinois river above Averyville, would that have any effect upon you in passing upon the question as to whether or not that water was in good sanitary condition?

A. Certainly I would consider it, but I don't think that it would have any effect. I would certainly consider the—

Q. Then you would recommend it?

A. No, not without considering the whole situation.

Q. Now then, we are at Averyville, and we remove all of the sources of pollution—would you still recommend it?

A. If there were no typhoid in Averyville among people who were drinking the water, I would recommend it.

GENERAL CROW: But remove your test; we are going to supply that water.

A. Yes, I have in mind to supply the water.

Q. That is not the point. It is what we are doing in this proposition. You come in here and state that this water was safe at Averyville—

11704 A. I would not recommend what was not safe.

Q. You wouldn't recommend anything that was not safe?

A. I have not said so. I said in my opinion.

MR. JEFFRIES: Is that opinion of sufficient strength to authorize you to advise people to use it for domestic and drinking purposes in the houses, taking it bodily from the river?

A. Not without tests, no.

Q. What kind of tests do you mean?

A. Observation of the whole situation, especially of people who drink the water.

Q. Then, doctor, you don't undertake to say that you can determine from what little information you have with reference to the physical character of the Illinois river, the source and extent of pollution at Chicago, that the effects of the Chicago sewage are not carried throughout the entire length of the Illinois river, having never made a test?

A. All the evidence is against such a view as you state.

Q. Well now, what evidence do you have reference to?

A. The chemical and bacteriological studies of the river that have been made show great purification of the river—

Q. You have examined them, have you?

A. I have examined the record, yes.

11705 Q. How did the bacteriological and chemical examinations of the water in the Illinois river compare with those taken at the Four Mile crib in Lake Michigan, which was known to be infected with typhoid fever germs?

A. I do not know.

Q. Did you make any comparisons there?

A. No, I have not compared it.

Q. Don't you know, doctor, that the water at lake Michigan that was known to be infected with typhoid fever germs contained only one to 300 bacteria per cubic centimeter?

A. I have not read the account.

Q. Which is less than one-twentieth of that contained at any time in the waters of the Illinois river, the Illinois river being subjected to the same source of pollution, to wit, the city of Chicago with its nearly 2,000,000 inhabitants, as was the Four Mile Crib in Lake Michigan at Chicago. Do you know that?

A. No.

Q. Did you take that into consideration in passing upon the sanitary condition of the water in the Illinois river?

A. I had not heard that it bears upon the sanitary condition.

Q. It has nothing to do with the sanitary condition of the water whatever?

11706 A. What we have to deal with, then, is how does the water of Lake Michigan bear upon the problem of the water in the Illinois river—

Q. Don't you know that the water has been condemned in Chicago, the water taken from the Four Mile Crib, when it did not contain more than one to three hundred bacteria per cubic centimeter in amount?

A. I know that people in Chicago have died of typhoid fever.

Q. Don't you know, doctor, that one cubic centimeter of water taken from a river may contain 10,000 bacteria in amount and another cubic centimeter of water may be taken from another river containing only about 300 or 100 or 10 bacteria per cubic centimeter in amount, and the water in the one river containing the less number of bacteria would be condemned, while that in the other would be recommended?

A. That is just the reason why I have been insisting on a biological test, as the most important one all through, exactly for that reason.

Q. Then you cannot express any judgment or any opinion as to the exact time when the disease producing bacteria or germs deposited in the Illinois river by the sewage of Chicago will disappear?

A. Yes we can, because there is no evidence of any
11707 typhoid infection being carried by water further than
75 miles, as far as I know.

Q. Further than 175?

A. No, seventy-five miles.

Q. Now doctor, doesn't that depend altogether upon the volume, source of pollution, amount of pollution, and the rate of flow?

A. Taking in all the conditions that have ever been witnessed, there is no evidence as far as I know of the typhoid infection being carried further than seventy-five miles by water.

Q. How far is Cumberland from Washington, D. C.?

A. I do not know.

Q. Where is your seventy-five mile case, doctor?

A. I put seventy-five miles as a limit, because all the cases I know about fell within that.

Q. Don't you know, doctor, that it has been traced by reputable epidemiologists and scientists from the city of Cumberland to the city of Washington, D. C., a distance of 175 miles, and that a typhoid epidemic in the city of Cumberland—the sewage of that city being discharged into the Potomac river, found their way into the—that the typhoid germs found their
way into the water supply of the city of Washington,
11708 and created and caused a typhoid epidemic at that city?

MR. TODD: I object to the assumption for the reason that the only evidence in this case is the evidence of Professor Sedgwick, and in his testimony he didn't know, and made no investigation as to whether there were any cases of typhoid between Cumberland and Washington City.

A. I didn't know that Professor Sedgwick had made that statement and I am surprised that so eminent and accurate a man as he should do so.

MR. JEFFRIES: The question is, do you know that it has been traced that far?

A. No.

Q. Doctor, the best sanitary test of the water in the Illinois river would be its use for domestic and drinking purposes would it not?

A. At any given place, yes.

Q. Do you know whether or not the people living on the Illinois river use the water for domestic and drinking purposes, from Grafton to the city of Chicago?

A. I should hope that they did not. I do not know.

Q. Now why should you hope that they did not?

A. Because I understand that typhoid exists in all those towns, and that the sewage passes into the river.

11709 Q. Doctor, without the sewage of Chicago is there any reason to believe that the water in the Illinois river would not be as reasonably safe for domestic and drinking purposes, as the water in any other river of that size in this western country?

A. Why, I should think there must be very great differences in the pollution of different rivers in this western country, and that some would be polluted much more than others, and that therefore one could not make a statement of that sort without knowing the typhoid conditions along such rivers.

Q. It is your judgment is it, doctor, that the sewage from Chicago with the 2,000,000 of people, has no effect upon rendering the water flowing down the Illinois river unsanitary from source to mouth?

A. No, I have not said anything like that; I am sure that I never said anything like that.

Q. It is your judgment then, it has no effect upon it at its mouth; is that it?

A. You mean at Grafton?

Q. At Grafton?

A. In my opinion the effect would not be appreciable.

Q. Do you know how many people live on the Illinois river between Lockport and Grafton?

11710 A. No, I do not.

Q. Do you know how many people reside upon the whole water shed tributary to the Illinois river between those points, exclusive of the city of Chicago?

A. No.

Q. Now then, exclude Chicago and the sewage thereform, from the Illinois river, would you recomend the water of the Illinois river at Grafton for domestic and drinking purposes in its present condition the population of towns and cities and the various industries upon its water shed?

A. I think it would be tolerably safe to use, but I would not recommend it.

Q. Why wouldn't you recommend it?

A. Because I would want to make tests and find out whether it was really pure or not.

Q. Why would you want to make the tests?

A. Because I think a test ought always to be made before any water is recommended.

Q. Tests for what, now?

A. Tests for—especially of the presence of typhoid bacilli, as shown by the occurring of cases among people who drank of the water.

11711 Q. Then you recommend that the people drink it to determine whether or not it contained infected matter?

A. No, they always do those things, or nearly always it has been done for you.

Q. What is it then that makes the water suspicious and unfit for domestic use without a test?

A. Without any test whatever?

Q. Yes?

A. Well, there would be no suspicion if we had not had tests made. Our suspicions have come from tests and from our knowledge of the way disease is propagated. The Eve man had no suspicion about the water. He drank it wherever he could get it.

Q. What is it that renders waters in rivers unfit for domestic purposes?

A. Ordinarily—

Q. Sewage and pollution, isn't it?

A. Ordinarily the presence of pathogenic bacteria.

Q. And they come from sewage?

A. Yes sir.

Q. And the more sewage the more pollution, isn't that true?

A. Yes.

11712 Q. Then if there are more people living in Chicago than there are upon the entire water-shed of the Illinois river below Lockport, the pollution in the Illinois river would be doubled by reason of the condition of the sewage from Chicago, would it not?

A. Not throughout the whole river, no. In my opinion the presence of ten typhoid cases at Peoria would be more dangerous for the river water at Pekin than the presence of 10,000 cases of typhoid in Chicago.

Q. If you knew that there were 10,000 cases of typhoid fever in Chicago and that the discharges of those patients were passed into the canal, would you recommend the water at Grafton?

A. No, not without—I wouldn't recommend it under any circumstances.

Q. Now if there were one thousand cases?

A. Under any circumstances, except those due to the lack of education and to politics of the country.

Q. If you knew that there were 100 cases of typhoid fever during the months of May, June, July, August and September in the city of Chicago and that the excreta of those patients were discharged into the sewers of Chicago, and thence into the
canal, and from the canal into the river, would you use the
11713 water of the Illinois river at Grafton, for drinking and
domestic purposes yourself?

A. I would boil it until we had more knowledge. I think it would be safe, but I would boil it until we had more knowledge about it. Boil it or filter it.

Q. Now then what is your reason for saying that you would boil it until you had more knowledge?

A. My reason is—

Q. I will ask you this: If your reason for saying that you would boil it is because of the uncertainity of ascertaining just how far the germs will travel and how long they will live, and because of the fact that the science has been unable to determine the length of life and the distance they will travel, and the conditions under which they live in a running stream?

A. My answer to that is that I always use the most perfect method whenever I can, in technique.

Q. Any thing then that added to the character of the water in the way of creating a suspicion in the way of creating a deleterious effect upon that water, in the way of giving an opportunity for the presence of disease producing germs, would render that water less valuable for domestic and drinking purposes, would it not?

11714 A. You mean commercially?

Q. Financially, commercially, sanitarily and every other way in which water is used?

A. Exactly in the degree I should think, in which the suspicion was believed to be well founded.

Q. How long do you think that the typhoid germ will live in a running water?

A. Under what conditions?

Q. Well, the ordinary river water?

A. Without any special sewage contamination?

Q. Without any special sewage contamination?

A. I don't know how long they will live.

Q. You have no idea upon the subject?

A. Well, I should think—it would be only a case—it would be a mere opinion. I should think that they would or might live as long as ten days. I don't think they would live longer than thirty days.

Q. Well, do you think they would live longer in the running water than they would in a sample of that water kept in the laboratory?

A. No, I think they would live longer in the sample.

Q. Don't you know that the general opinion of all bac-
11715 teriologists and epidemiologists and scientists upon that
subject is that they will live longer in the running stream or in a large body of water than they will confined in prison where they are kept from oxygen to a large extent, in a bottle in the laboratory?

MR. TODD: I object to that question for the reason that it calls upon this witness to pass judgment upon the testimony of other witnesses who have already testified to the contrary in this case.

MR. JEFFRIES: That is true.

Q. I will ask you this question, if the literature upon the subject and the writings of scientists, bacteriologists and epidemiologists do not hold they will live longer in the running stream or in a large body of water like a lake, than they will in the sample of water contained in the laboratory?

A. I do not recall direct statements about the matter.

Q. I will ask you now if you yourself do not believe that reasoning from analogy, that the typhoid bacteria will live longer in the Chicago drainage canal than they will in a sample of water taken from the Chicago drainage canal and placed in the laboratory, for the reason that while it is contained in
the canal, fresh water is continually being added to it,
11716 and it washes the deleterious matter, the objectionable
matter away from it—the toxins away from it; it is able to swim itself; it is motile and swims away from its objectionable influences, while in the laboratory sample of water it is a confined prisoner, and if the literature upon that subject does not reason from analogy in that way and take the position that they will live longer in the running stream than they will in the sample?

A. I have heard very conflicting statements about this, but I have never gone into the subject enough to offer an opinion on it.

Q. Now whom have you heard make conflicting statements?

A. I have heard someone say, I do not know who it was, at the moment, that substances dissolved out of the glass in bottles that are helpful in keeping bacteria alive. It has been proven of course that chemical substances do dissolve out of glass when fluids are kept in bottles for a while; but in my opinion on this—I have no opinion on it.

Q. I thought you stated a moment ago that you were of opinion that they would live longer in the laboratory sample?

A. Well, it is not a strong opinion. I have that idea about it. It is not a strong opinion.

Q. Then you do not care to express an opinion on it?

11717 A. I would rather not.

Q. You don't care to express an opinion as to how long they will live in the Illinois river?

A. No, I do not like to—a definite opinion.

Q. They might live five days? They might live thirty days?

A. I don't think they would live more than thirty days. I don't think in the Illinois river they would live that long, if they started in the upper part of the river.

Q. What is the difference between the Illinois river and any other river that you are imagining now?

A. The amount of sewage in the river.

Q. What is the cause of that amount of sewage?

A. At Chicago it is sewered into the river, and they die very quickly where the sewage is abundant.

Q. Would that be true in winter?

A. I should think so.

Q. They would die just as fast in the winter as in summer?

A. No, I think they would die faster in winter in sewage contaminated water, than they would in water not contaminated by sewage.

Q. Well, would they die faster in sewage contaminated water in the drainage canal in the winter time than in the summer time in that same water? 11718

A. No, I think they would die faster in the summer.

Q. Then they would disappear more rapidly from the canal in the summer time than in the winter time?

A. That would be my opinion.

Q. Now that is your opinion with reference to disease producing germs in the summer time and winter time?

A. Based on the mean, between the two.

Q. Is that the correct way of basing opinions—would a mean be proper?

A. No, it would not.

Q. Is there any fairness in mean opinions?

A. No, it ought to be based upon the worst possible circumstances.

Q. It ought to be based upon the worst possible circumstances?

A. Yes.

Q. And can you say that under the worst possible circumstances, that the sewage of Chicago will in no wise affect the water in the Mississippi river at Grafton?

A. I think it very improbable that it would.

Q. Will you say that under no circumstances it will not
and cannot affect the sanitary condition of the water in
11719 the Mississippi river at Grafton?

A. I didn't make any definite statement.

Q. Well, do you say that now?

A. No, I said in my opinion it would not.

Q. Well, the saprophytic bacteria would not grow in the drainage canal in the winter time, would they?

A. Some would, I imagine.

Q. It would be a very slow growth though, wouldn't it, and as the water approached the freezing point it would be less would it not?

A. Yes, certain kinds.

Q. And when the water was frozen there would be no growth?

A. Of some kinds of saprophytic bacteria; some are influenced much more than others.

Q. What kinds?

A. I don't know.

Q. You know this, that there is a certain kind of water bacteria that grows faster in winter time than in summer time, but the saprophytic bacteria that come from sewage, and that are caused by sewage grow more rapidly in the summer time than they do in winter. Do you know?

A. I do not know.

Q. Don't you know that to be a fact?

11720 A. I don't know.

Q. You have never seen that?

A. I don't recall it at the moment.

Q. Doesn't it seem reasonable to believe that they would?

A. It might be reasonable.

Q. Well, isn't it reasonable?

A. I think either view could be reasonable.

Q. If that is a fact would it affect your opinion in any way?

A. I think the typhoid bacilli would die less quickly when the saprophytic bacteria,—one of the important factors—are slow in growing.

Q. But there are practically no saprophytic bacteria present when the water is frozen over with ice, are there?

A. Why, I think that they are present, and I believe that I would have included water bacteria among the saprophytic bacteria as a classification. Of course that is simply a matter of differentiation.

Q. But the water bacteria have no tendency to destroy the sewage?

A. Is that true? I did not know that.

Q. I am asking you. I am not a bacteriologist.

A. I suppose that they do.

11721 Q. I don't want you to think that I am a bacteriologist now; I am asking you?

A. Well, it is my opinion that they do.

Q. That the ordinary water bacteria destroy sewage?

A. Yes.

Q. And it is your opinion also that the ordinary water bacteria have a very extensive effect upon the life of the typhoid bacillus?

A. Yes.

Q. Now then, will you tell me how the water bacteria destroy the sewage, and how they destroy the life of the typhoid bacteria?

A. Well, the details of the process are not known. We know it happens; we know that they die out, and chemists and bacteriologists are working on the problem, trying to find out just how it happens.

Q. Then you don't know that they do?

A. Because waters do get purer.

Q. Well, how do you know that the water bacteria kill them?

A. I do not; it is only my opinion that they do; that they along with the—

Q. Does anyone else share that opinion with you?

A. I don't know.

11722 Q. Did you ever read it anywhere?

A. I do not recall having read it; but it seems to me probable.

Q. Is that not an important factor in forming your opinion?

A. Well, I have only thought of it at this moment.

Q. Then you didn't take that into consideration?

A. I had not separated the water bacteria particularly in my mind, from the bacteria in the sewage, but I do now, as you call my attention to it.

Q. But that would be a factor and while the water bacteria might increase very rapidly in the winter, certain kind of them, yet there would be another kind of bacteria that comes from the sewage itself, that would not increase in winter time?

A. It is a most interesting problem to investigate, I think.

Q. And as they fail to increase, the unpurified sewage would go further down the stream?

A. Unpurified sewage?

Q. Unpurified sewage?

A. I think so. How much further, I don't know.

Q. If the river was completely frozen over with ice for six to eight weeks of the year, they could probably travel very comfortably under the ice at a temperature of 32 to 33

11723 degrees could they not,—pathogenic germs?

A. Against the view that they do is the fact that typhoid is rare in winter and most abundant in the autumn and spring, when everything is melted up.

Q. You don't mean to say that there is no typhoid in the winter time?

A. No, but it is far less abundant.

Q. Is that true generally?

A. Yes, generally.

Q. Haven't some of the greatest epidemics in the history of this country occurred in the month of February?

A. Oh, there might be a great epidemic in any month of the year.

Q. Isn't it true as a matter of fact that nearly all of the epidemics do occur in the winter time or in early spring?

A. The spring and autumn are the two times.

Q. The autumn has the greater number of cases?

A. There are more cases in the autumn than in the spring.

Q. More cases because they occur generally all over the country?

A. More cases where they are much infected.

Q. More cases of epidemics?

11724 A. An explosive epidemic might occur at any time, but where it is due to continual pollution of the water supply the autumn cases are the most numerous.

Q. You mean to say then that they would not pass down under the ice and produce an epidemic?

A. You mean to St. Louis?

Q. Yes.

A. In my opinion it would not occur.

Q. What is it that makes you believe that?

A. I think that sedimentation alone would not be sufficient.

Q. If the sedimentation in the Illinois river was sufficient to remove them—by the way, is it not true that this lake at Baltimore that you spoke of, and the Lake Michigan at the Four Mile Crib and the lake at Toronto, would not be sufficient to eradicate them by sedimentation?

A. There would be if there were a continual access of new bacilli.

Q. Aren't there new and continual accesses here in the Illinois river?

A. Yes, but they have to go so far that the opportunity for sedimentation is very great, whereas, in these other instances they do not have to travel so far.

11725 Q. Is it the distance or the water that causes sedimentation—the condition of the water,—the distance traveled by the water or the condition of the water?

A. Why, sedimentation is going on all the time, and as water goes along, sedimentation is occurring. The further it goes, naturally the more is droped out.

Q. And these motile bacilli are continually settling, even in a running stream?

A. Yes, the motility of the typhoid bacillus would have comparatively little effect upon this.

Q. How would that be in flood time? Sedimentation would take place there too, wouldn't it?

A. To a certain extent; it would not occur so quickly.

Q. Assuming now that in a river it has been known to pass a distance of 175 miles, so that an epidemic at one point created an epidemic at a point below 175 miles, is it not reasonable to believe that it might be carried much further than the 175 miles, provided the time of travel is within the life time of the typhoid bacillus?

MR. TODD: I object to the question on the ground that it assumes that an epidemic originated at a distance of 175 miles.

A. The fact that we have no evidence that I regard as reliable—

11726 MR. JEFFRIES: We are not talking about having evidence; I am talking about this question now.

MR. TODD: I submit that you ought to let him answer the question.

A. That is what I am basing my opinion on.

MR. JEFFRIES: I beg your pardon for disturbing you, but I thought you didn't understand.

A. The fact that we have no evidence that I regard as reliable that an infection has been water-borne, for a distance of 175 miles, makes me think that the sedimentation process would be sufficient to eliminate it before it got—

Q. When you mention that you have no evidence of it, you simply mean that you have not observed it?

A. No evidence with which I am familiar in the literature, which I regard as reliable.

Q. Now doctor, assuming that a town situated upon the banks of a river is affected with a typhoid fever epidemic; that the sewage of that town is discharged into the river, and that the sewage so discharged affects the water supply of another town 175 miles below, and creates a typhoid epidemic among the people using that water of the river at that point for domestic and drinking purposes; is it not reasonable to believe that 11727 the typhoid germs thus carried a distance of 175 miles might not be carried to any other distance down the river so long as the distance did not exceed the life of the germ; isn't that true?

A. I don't think it would be reasonable to believe it until we had evidence that it happened.

Q. Assuming that it happened?

A. I don't think that we have any reason to believe that it would go further unless there was evidence that they had gone further.

Q. If it had gone 175 miles and it is not dead, isn't it reasonable to believe that if it is in that water, it will go further?

A. Yes, it is reasonable to believe it might go somewhat further, but how far one could not guess.

Q. If it has gone 175 miles down the river and is still alive in five days, isn't it just as reasonable that if it lives ten days, it may travel another 175 miles?

A. Assuming what you say, I don't think it would be unreasonable to believe.

Q. It is entirely reasonable to believe that if it has gone 175 miles, that it would, if it lives, long enough, travel another 175 miles under the same conditions?

A. Yes, that is a fact.

11728 Q. Doctor, what practical experience have you had in reference to the water supply of cities and investigation of those water supplies, and in the formulation of the water system for a city?

A. None at all.

Q. Have you had any practical experience in the study of any particular water supply for the purpose of determining whether or not that water was in a sanitary condition and suitable for domestic use?

A. I have made an analysis of private water supplies at Baltimore.

Q. You made the analyses of the water in the laboratory?

A. Yes.

Q. But as I understood you yesterday your work at Baltimore was not of sufficient scope to take in all the circumstances and physical facts surrounding the water supply?

A. Of the city of Baltimore as a whole?

Q. Yes?

A. No, I never investigated the city water supply of Baltimore as a whole, but I did examine the water for Mrs. Garrett,—private water supply, bacteriologically.

Q. Then you never examined the water supply of any city with the view of determining whether or not it was suitable for domestic and drinking purposes? 11729

A. No.

Q. Now you say you have examined a private water supply at Baltimore?

A. Simply bacteriologically—a bacteriological examination.

Q. Do you know the source of the water that you examined?

A. I know that it was sent to me in a bottle.

Q. But you don't know whether it was sent from a lake, river or well?

A. I knew at that time.

Q. You didn't go and collect the sample yourself?

A. No, it was collected for me by a medical man with the request that I make the bacterial examination.

Q. And he didn't tell you whether it came from a well or a spring?

A. Yes, he did, but I do not recall now.

Q. From that bacteriological analysis did you determine whether or not the water was suitable for domestic and drinking purposes?

A. Oh, I told him the number of bacteria per cubic centimeter in the water, and compared that with statements in the literature as to what was regarded as an over-polluted water
supply; but I pointed out to him at that time that such an
11730 analysis in the absence of a biological test, in my opinion,
was not sufficient to permit one to pass finally.

Q. Do you remember how many bacteria there were in that water?

A. No.

Q. You expressed no opinion as to the sanitary condition of the water at the time?

A. I expressed a relative opinion at the time.

Q. Do you know what that opinion was?

A. No, I do not recall.

Q. You don't know whether you told him the water was safe or unsafe?

A. As I recall it, it was, as compared with other waters, a safe water, but I do not recall the details.

Q. Now might it not have been doctor, that that sample that you examined, was taken from a well subjected to sewage leaking, and was highly contaminated with sewage, and yet have no large number of bacteria?

A. No, I don't think so.

Q. Isn't it a fact doctor, that water is often condemned that contains a very small number of bacteria, while other water containing a large number is recommended?

MR. TODD: I object to the question, as it is the identical question that was asked yesterday.

11731 MR. JEFFRIES: That is true, but in view of what
he has already said I want to determine just the character of the witness' opinion on the subject.

A. I think I answered that in the affirmative yesterday.

Q. You did not examine the water with the view of determining the character of the bacteria that you found in it?

A. Yes, I examined it especially for the bacilli of the colon group.

Q. Doctor, why do you examine water particularly for the purpose of ascertaining the colon bacilli?

A. Our experience has shown that if there are large numbers of the bacilli of the colon group present, it makes one very suspicious of sewage contamination.

Q. Now the more the sewage there is in the water, the more coli, is that true?

A. If the sewage be largely human excreta that would be true.

Q. Now the more coli that you discover in the water the more dangerous the water would be considered, would it not?

A. Not necessarily. There again, everything would depend upon the number of really pathogenic organisms in the sewage.

Q. But in expressing an opinion, you cannot find the pathogenic—the real pathogenic germs in the water, can you—
11732 you are not likely to find them?

A. The biological test is the best way.

Q. We are cutting out the biological test. We are speaking bacteriologically—the more coli bacilli that you find in the water the more the sewage pollution is apparent from the analysis, is it not?

A. Other things being equal, I should say that was true.

Q. Now, what other things being equal?

A. I mean to say, fairly constant conditions with regard to the destruction of bacteria in the water.

Q. Well, the same conditions that would destroy other bacteria would destroy the colon, would they not?

A. Well, that is what I mean, that if there happened in the particular stream to be something that would kill off colon bacilli, there might have been greater sewage pollution.

Q. Now, we are talking about the analysis of a particular sample of water, where you obtain a large number of the colon bacilli, that water is to be assumed—or condemned as sewage polluted?

A. The water is to be suspected of sewage pollution.

Q. Doctor, isn't it a fact that if you find a large number of colic bacilli in water, you condemn it as sewage polluted? If that is not true, why is it necessary to take into considera-
11733 tion the number of colon bacilli that is found in the samples of water, for the purpose of determining its sanitary condition?

A. I am not sure that the presence of colon bacilli is absolute proof of sewage pollution. I think colon bacilli might be in the water without—

Q. I understood you to say, Doctor, that when you found large quantities of colon bacilli in water, it was not as a general proposition, safe water to be used?

A. I said I would regard it as suspicious of sewage contamination.

Q. Well, I will ask you this question: if it is not a fact that the more the sewage the more the colon; the more sewage you have deposited into a stream, the more colon bacilli you will find in analysis of the water in that stream?

A. As a general statement, I think that would be true, but scientifically you would have to modify your statement by a lot of proportions. There is sewage and sewage, and there are waters in which sewage comes, and there are all sorts of environments and circumstances that would alter it.

Q. Then your judgment is that that is absolutely worthless?

A. Not at all. I think it is one of the most valuable
11734 means of giving us ideas with regard to sewage.

Q. Now, what other kinds or character of bacteria in sewage, speaking as a bacteriologist, do you consider in passing upon the sanitary condition of the water?

MR. TODD: I object to the question, as the witness has not qualified as a bacteriologist, and is not placed on the stand as a bacteriologist.

MR. JEFFRIES: He was qualified as a bacteriologist; he taught bacteriology.

MR. TODD: I submit that that is not born out by the record. He is an epidemiologist and pathologist, and every question I asked was along those lines.

GENERAL CROW: Do you base the objection on the proposition that he is not a bacteriologist?

MR. TODD: No, I base the objection on the fact that he was not put upon the witness stand as a bacteriologist and cross-examination as such is improper.

Q. (Question read).

A. Well, if I am to answer that question, I would say that I would consider especially the bacteria of the bacillus lactus aerogenes group, and of the proteus group.

Q. MR. JEFFRIES: Which of the three would you consider the more important?

11735 A. I would consider the colon bacillus the more important.

Q. Then it is true, isn't it, Doctor, that if you find a large number of colon bacilli in the water, that water is condemned at once by a bacteriologist, as being sewage polluted water?

A. I think it ordinarily would be. I think there might be waters with large numbers of colon bacilli in them, that would not be dangerous.

Q. Then the more sewage, the more colon?

A. In a general way.

Q. Then I understood you to say yesterday that the more sewage the more rapid would the pathogenic bacteria decrease. Now, how do you reconcile the two statements, that the more the colon bacilli the greater the probability of sewage pollution, and also that the greater the sewage pollution the greater the destruction of pathogenic germs?

A. Well, we were talking of particular pathogenic germs, and especially of the typhoid bacillus.

Q. Is not colon bacillus considered a pathogenic germ?

A. It is a very mildly pathogenic germ, and is classed by many as non-pathogenic.

Q. Who classes it as non-pathogenic?

11736 A. In the literature this was often referred to as a non-pathogenic germ, of course we know that it is pathogenic at times.

Q. Then the water would not be condemned because it contained the colon bacilli?

A. I think it would be regarded as very suspicious.

Q. And suspicious because the presence of the colon meant the presence of pathogenic bacteria?

A. Because it would make it probable that if it came from a typhoid infected city, that typhoid bacilli were present.

Q. Now, Doctor, the presence of the colon indicates the presence of sewage pollution, and the presence of typhoid bacilli?

A. Not necessarily, no.

Q. In the event it comes from an infected district?

A. It makes it probable.

Q. It makes it probable. Then, how do you reconcile the statement that the more sewage is discharged into a certain quantity of water, the greater the destruction of the pathogenic germs, such as typhoid bacilli, with the statement that the presence of the colon bacilli is indicative of the presence of the typhoid?

A. I say it is not indicative absolutely, but it arouses suspicion of the presence of typhoid. As I said before, there
11737 might be many colon bacilli with no typhoid bacilli present.

Q. You condemn the water because it contains colon bacilli, and the reason you condemn it on account of the presence of colon bacilli, is because it is sewage polluted and contains typhoid germs?

A. Might contain typhoid germs.

Q. Might contain typhoid germs?

A. I did not say that I condemned it; I said that I would be suspicious of it.

Q. And the more colon the more likelihood of typhoid germs?

A. No, I don't think that would follow at all. That would not follow.

Q. And the more sewage the greater the opportunity for the destruction of the typhoid germs?

A. That is a matter of relative proportion in the water; as I understand it, it is the percentage of sewage to water. It would not matter about the total bulk of sewage and water, but the percentage of the sewage and water in any given bulk.

Q. Doctor, supposing twice the amount, twice the number of the colon bacilli was found in the Chicago river prior to the opening of the Chicago drainage canal, that are found in the drainage canal today, what would you say as to the sanitary condition of that water?

11738 A. I do not know of any special inference that could be drawn from that.

Q. Would you say that there were less or more pathogenic germs in the water?

A. I don't think one could make a statement about that.

Q. Well, the condition of the water, you said yesterday, I believe, had a tendency to prolong the life of the typhoid germs, and the condition of the water would have a tendency to dilute the colon and render the number per cubic centimeter less, would it not?

A. But—

Q. Now, might not and would not, under those conditions there be more danger in a sample of water that contained the less number of colon than there was in samples containing a greater number of colon?

A. But I did not assume that the colon was the only saprophytic bacillus.

Q. Well, wouldn't that be proper?

A. I don't think it would.

Q. Isn't it a fact that if large quantities of colon bacilli were found in the Chicago river prior to the opening of the drainage canal, and that since the opening of the canal smaller quantities have been found in the water in the drainage 11739 canal than were found in the Chicago river prior to the opening of the canal, would not that indicate from the colon contained, that there was less danger since the opening of the canal than prior to the opening, and would it also not indicate from what was said yesterday, with reference to the condition of water, that there is more danger since the opening of the canal because the life of the germ has been prolonged by the addition of water, than there was prior thereto?

A. In other words, you mean that the one factor would diminish the danger and not in any other way was there an increase of danger?

Q. Now, is that true?

A. I think that could be argued.

Q. Now, if it appears, Doctor, that prior to the opening of the canal there were a larger number of colon in the waters of the Illinois river, and that since the opening of the canal there has been a decrease in the numbers; what significance would you give to those conditions, from what you have just said upon that subject?

A. I think very little significance could be given to it. It might mean that there was less sewage.

Q. Might it not mean this, and does it not mean this, Doctor,
that the failure to find the large numbers of colon bacilli in the
Illinois river since the opening of the canal, does not
11740 mean that they are not present, but means by the ad-
dition of the water that they have been further removed,
and that by that addition of water they themselves—their life
has been prolonged, and the life of the typhoid germ, and of
other bacteria in the water has been prolonged, and that there
is more danger in the diluted condition than there was in the
extremely polluted condition, prior to the opening of the canal?

A. It might.

Q. Well now, isn't that a fact?

A. It might mean that there has been increased destruction of the colon bacillus.

Q. What would bring about the increased destruction?

A. The various bacteriological influences that operate.

Q. What do you mean by the various bacteriological influences?

A. Any influence that will kill bacteria.

Q. Now I understood you to say yesterday that the more sewage you added in any quantity of water, the greater would be the destruction of the bacteria in that water?

A. Of the typhoid bacillus.

Q. And the more water you added the longer they would live?

A. Other things being equal.

11741 Q. What other things do you have reference to?

A. All the environmental circumstances.

Q. What are the environmental circumstances—

A. Chemical and physical.

Q. Name some of them?

A. I have done that before. I will gladly do it again. Physical influences, include air, light, temperature, electrical influences, chemical influences, and so on.

Q. Well now, those conditions were all the same after as before?

A. I am not sure that they are.

Q. Do you know anything about it?

A. I don't know the details of it, but I should think that there might be some differences.

Q. Then if you do not know the details of it and don't know that the conditions have been changed, why do you undertake to pass an opinion on the sanitary condition of the water in the Illinois river, and why do you undertake to designate a particular point in the Illinois river where it has become pure and has lost all of the pathogenic germs that have been discharged into that river by the sewage of Chicago?

A. In the first place I have not designated as you indicate.

Q. Did you not designate Averyville?

11742 A. And in the second place my opinion is based upon my general experience as a physician and epidemiologist.

Q. Did you not designate Averyville as the place where the water in the Illinois river, since the opening of the canal had lost all of the pathogenic germs, and was a safe water for domestic and drinking purposes?

A. I did not.

Q. So far as Chicago is concerned, did you not?

A. I said that in my opinion it would be a safe water at Averyville, if everything could be eliminated except the Chicago sewage.

Q. Would you recommend that water?

A. No.

Q. Eliminating all other sources of sewage?

A. No.

Q. Now then, if you don't know anything about these physical facts, including light, air and volume of water and other surrounding circumstances, which you stated were necessary, why is it that you formed an opinion as to that—why do you designate Averyville as the point where it would be a safe water?

A. From the chemical and bacteriological status of the water, and comparison in general with the purification of streams. 11743

Q. What are the chemical and bacteriological results there at Averyville?

A. Well, I haven't them with me, but I have examined them.

Q. Well, can you tell about what they are?

A. Well, in general the self-purification has gone on to a very remarkable extent.

Q. Are you a chemist?

A. I have done chemical work, but I would not designate myself as a chemist.

Q. What one particular chemical constituent in water is considered by you in your laboratory, and as a physician, as being the most suggestive of sewage pollution?

A. I don't think that I ought to be questioned on chemical analyses of water. It is not my fach.

Q. Then doctor, if you don't care to be questioned upon the chemical situation, why do you say that it is necessary to take into consideration the chemical analyses of the water in passing judgment upon the condition of that water, and if it is necessary to have the chemical analyses of the water or chemical tests in order to express judgment, why have you expressed judgment upon the sanitary condition of the water in the Illinois river?

11744 A. For the reason that I believe in getting all the facts together bearing upon the subject when one is passing a judgment upon it.

Q. Doctor, do you believe that you as a layman, would probably appreciate the significance of the chemical results obtained from the analysis of the water in the Illinois river or any other water, not being a chemist yourself?

A. I think that I know enough chemistry and know enough eminent chemists, to be able to appreciate the work of a chemist; to be able to find out how good a chemist's works are.

Q. Now isn't it a fact that chemists who examine water for the purpose of determining its sanitary condition, have designated certain chemical constituents in water which are the most indicative of sewage pollution?

A. Yes, there are differences of opinion even among the chemists.

Q. Now then what class of opinions do you accept?

A. I at any one time try to find out the opinion of the men who are recognized as the leaders in the subject.

Q. Who do you recognize as the leaders on that subject?

A. The way I would find out at the moment, because the leaders change from year to year, and the men whose opinion should be regarded--

11745 Q. Who are the leaders of this day?

A. I would go to my friends in chemistry, and men whom I know are eminent in chemistry, and talk to them about it.

Q. Is that the way you did at Averyville?

A. I talked to an excellent chemist.

Q. And you have expressed your opinion altogether on what an excellent man has told you?

A. No.

Q. So far as the chemical situation is concerned?

A. So far as the chemical situation at Averyville is concerned, yes.

Q. Just what he told you, you have relied upon that?

A. Yes sir.

Q. Now wasn't that Professor Long?

A. He was one of the men.

Q. Who else?

A. Dr. Jordan.

Q. Is Dr. Jordan a chemist?

A. I don't know how much chemical work he has done, but I think he has made chemical analyses.

Q. Well, do you know whether he is a chemist or not?

A. I don't know that he would be called a chemist.

Q. Why do you rely upon his chemical analysis?

11746 A. I would regard his opinion of other men's chemical analyses.

Q. Then I understand you to say that you are undertaking to give what Professor Long believes in references to the situation at Averyville chemically speaking?

A. Particularly the Averyville situation, yes.

Q. Is that true?

A. Yes.

Q. And you know nothing of the conditions at that point other than what you have learned from them?

A. With regard to the chemistry, no.

Q. You have talked it over with them and they agreed on that, that that was the point which you should determine and should designate, as the water being chemically pure?

A. I have not designated that the water was chemically pure there.

Q. (Question repeated)?

MR. TODD: The question is, did they agree that you should?

A. No, they have not told me to do anything.

Q. MR. JEFFRIES: Did not both of those men tell you that that was the point where the water, chemically speaking, was safe?

A. No, not in those words at all.

Q. So far as the Chicago sewage was concerned, and did you not go to them directly to get that information for
11747 the purpose of using it in your testimony here?

A. No; I got it before I had any idea of testifying in this case at all.

Q. Why did you get it?

A. Because I meet these men socially and talk over the general sanitary conditions, and medical conditions from time to time; because I am interested in these problems. I had no idea that I should testify in the case at all at that time.

Q. Have you talked with them since you had an idea that you would be called upon to testify in the case?

A. I have talked with Jordan, but not with Professor Long.

Q. What did you talk to them about?

A. About the general situation of the problem.

MR. TODD: I suggest that in view of his last answer, that he has only talked to one, as he stated, the question assumes that he talked to both since the time referred to.

MR. JEFFRIES: Well, he did talk to both of them.

THE WITNESS: Not since.

Q. Since you have been called upon you only talked to one, but you talked to both of them before?

A. Yes.

Q. Then doctor, you are simply expressing Professor Jordan's views on the situation, are you not?

11748 A. Not at all. In addition to his views we have all the evidence with regard to self-purification of streams which is in the literature to guide us.

Q. And the self-purification in the literature is just such as you referred to yesterday?

A. Yes sir.

Q. And all the purification had reference to the bacteriological purification and not with reference to the purification from the pathogenic bacteria?

A. I referred to my work that has been done on the subject.

Q. Well, isn't that true now, doctor?

A. It includes pathogenic as well as non-pathogenic.

Q. Isn't it a fact that those works pay no attention whatever to the appearance and disappearance of pathogenic germs, but deal entirely with the total number of counts of bacteria contained in the water?

A. If you will turn up the journals it will be possible for you to see exactly what they deal with. I can give you the references.

Q. Isn't that true?

A. I wouldn't want to make definite statements as to the exact nature of those articles, without having them by me. There are too many to carry in one's head.

11749 Q. Do you know of any one article that undertakes to state so far as the purity situation is concerned that they have determined from a bacterial standpoint, the particular place in the river where it is free from pathogenic germs when sewage from a city has been discharged into it?

A. As I pointed out yesterday, I do not think it is possible to do that under any conditions.

Q. I asked you if you know of any one article or any one man who has written an article upon the situation of purity, who has observed from his examination a complete disappearance of the pathogenic germs from the river after the sewage had been discharged into it above?

A. It seems to me that I have answered that question several times.

Q. Well, I want it answered again. I want to know if you know of any man that has written a book—I want to know what book it is, what article it was and where it is, and where it can be found?

A. All the literature bearing on that subject will be found referred to in Baumgarten's Jahresbericht.

Q. I want to know if you know of any piece of literature, either in pamphlet form or in book form, being published, or any man who has undertaken to investigate, and his investiga-
11750 tion shows or discloses a complete disappearance of pathogenic germs from a running stream below the point at which the sewage was discharged into that stream? Do you know or do you not know?

A. As I have said already, all the literature on the subject would be revealed in Baumgarten's Jahresbericht. I am giving you the name of the book and the name of the man.

Q. Well, does he undertake to say that he has made any such investigation and made any such determinations?

A. I cannot tell you what he says without turning up the volume.

Q. Then doctor, you haven't given that sufficient importance to impress it upon your mind, although you are a pathologist, and bacteriologist and an epidemiologist; is that true?

A. There are a great many things that I do not carry in my mind.

Q. Don't you think that as an epidemiologist, that that is a very important question, and don't you know that if it could be determined accurately and safely, that there would be no difficulty in naming the men who had made the determination; isn't that true?

A. If it could always be determined accurately and safely, it would be of course very valuable.

11751 Q. Now I want to know, doctor, if there is any man, epidemiologist, biologist or bacteriologist, that has ever made that character of a determination with reference to the pathogenic or disease producing germs?

A. With regard to the cholera, or any pathogenic germs?

Q. Of pathogenic germs being removed from the stream after the sewage discharges had been deposited in it?

A. I don't suppose any such research has ever been made, determining the complete absence of any pathogenic germs, from a stream.

Q. Doctor, with the addition of 250,000 cubic feet of water per minute in the water of the Illinois river, what is your judgment as to there being a greater number or a less number of bacteria per cubic centimeter, since the opening, than there was prior to the opening of the canal, in the Illinois river?

A. At all points in the Illinois river?

Q. At any point and all points?

A. I should think that there must be some pollution.

Q. What do you mean by that; less or more?

A. That would mean fewer bacteria.

Q. Fewer bacteria since the opening of the canal, is that true?

A. I am speaking theoretically now. I am merely offering 11752 an opinion.

Q. Well, you are speaking theoretically based upon your laboratory experience, are you not?

A. Yes, and reading.

Q. Now do you know as a fact whether or not the bacteriological results show that?

A. I don't know the comparisons between individual points before and after the opening of the canal.

Q. You made no comparisons?

A. No.

Q. Did you not state doctor, that the water at Averyville was in good condition because of the comparisons that you had made?

A. Before and after the opening of the canal?

Q. Yes?

A. No, sir.

Q. Then all that you know is what was done after the opening of the canal and what has been told you by Professor Jordan and Professor Long?

A. And what has been written about it, yes.

Q. What was written about it after the opening of the canal or before the opening of the canal?

A. After the opening of the canal.

11753 Q. And which related solely to conditions after the opening of the canal?

A. Well, there were references to the conditions before the opening of the canal in some of the articles.

Q. Did you consider those?

A. Yes, but there were no data as to the actual number of bacteria at any particular spot in the stream that I recall.

Q. Wasn't that important?

A. That would be very desirable.

Q. Isn't it important to know this?

A. Certainly if they are available. Are they available?

Q. Do you know that they conducted experiments for a year and a half before the opening of the canal—Professor Jordan and Professor Long? Do you know that?

A. I wasn't familiar with it at the time.

Q. Well, didn't you ask for that information when you were talking to Jordan and Long, and before you went upon this stand?

A. I didn't talk to Professor Long before coming on the stand.

Q. But when you found that you were coming on the stand?

A. I only had two or three days notice.

Q. You made no demand for those facts?

11754 A. No.

Q. Not deeming them necessary at the time, but now you say that it is necessary?

A. I have not said that it was necessary for my opinion.

Q. Wasn't it an important matter?

A. There are a great many things that would be desirable and important, but I am here to give evidence on what I am familiar with.

Q. Now just state what you are familiar with?

A. I am familiar with the clinical and pathological phenomena in typhoid fever and malarial fever, with a great deal of knowledge regarding epidemics.

Q. Now then doctor, basing your judgment upon your clinical and pathological experience, in the laboratory and hospital, I will ask you if you consider the analysis of water made by a chemist and bacteriologist, sufficient to give you information to determine as an epidemiologist, the sanitary condition of water?

A. I think they, together with the biological observations offer the most important axercerviates we have for making such determinations.

Q. Can your biological observations indicate to you what is likely to happen in the future?

11755 A. Well, as that is a very general question, my answer would have to be very general. In a general way, yes.

Q. And all conditions that might arise in the future?

A. Your question is so general that I do not think a specific answer—

Q. Well, I make it general so that you will answer it.

A. My biological observations in the past would hardly determine the character of the sun spots in future. I think your question is too general.

Q. But we are applying conditions to the Illinois river or to any river about which you are speaking. We are not talking about the spots on the sun.

A. I think that the biological features will always be very important; very important.

Q. And you can determine by the biological evidence just what the conditions are going to be in the future? I am asking you now for the sanitary results that are liable to happen in the future?

A. I would not be rash enough to make any prophecy as to the future, no; the past is the best guide we have to the future,—and the present.

Q. Now there is, as I understand you doctor, by the addition of the 250,000 cubic feet of water per minute, a less 11756 number of all kinds of bacilli per cubic centimeter or per given quantity of water, or in the Illinois river?

A. There would be the moment the water was mixed.

Q. Would not their opportunity for destruction be less by the addition of the water, than it would be prior thereto?

A. The oportunity for the typhoid bacillus to be destroyed immediately would be lessened possibly. I don't know whether the dilution is great enough to make much difference there.

Q. Did you study the amount of dilution?

A. No.

Q. The ratio?

A. No.

Q. Or proportion?

A. I cannot give you that.

Q. Is that not important?

A. Yes, that is not a part of the evidence which I am called here to give.

Q. Then doctor, if there had been nothing except Chicago river water turned into that canal, would it be safe at Averyville under existing conditions?

A. Under existing conditions?

Q. Yes?

A. I should not think so.

11757 Q. Then the addition of the water must have had some effect upon it?

A. I have said that river water is never quite safe, haven't I, to be recommended, at any rate.

Q. I understood you to say that in your opinion the water in the Illinois river had lost all the pathogenic germs by the time it reached Averyville—I mean pathogenic germs from the city of Chicago?

A. If all others on the way had been excluded?

Q. If all others on the way had been excluded?

A. I said in my opinion it would be safe, though I would not recommend it.

Q. And I not only understand you to say that, doctor, but I believe you said that under the present conditions, that the water in the Illinois river at Averyville in your judgment was free from the sewage of Chicago and was reasonably safe, did you not?

A. As far as Chicago itself is concerned.

Q. Taking into consideration conditions as they now exist, with the cities of Joliet and LaSalle and Henry and other places on the Illinois river, did you not say yesterday that in your opinion the water of the Illinois river was reasonably safe at 11758 Averyville?

A. I don't recall what I said yesterday on that point.

Q. Well, what do you say now?

A. Well, I should say that considering the existing conditions of towns along the bank, an unprotected water-way, that the water ought to be filtered or boiled before it is used.

Q. Would the sewage of Joliet have any effect upon it?

A. How far is Joliet from Averyville?

Q. You testified about the conditions, doctor; you ought to know the distance of Joliet?

A. Well, I have it here, but I don't carry those things in my head absolutely.

Q. Well now, I ask you, would the sewage of Joliet have any effect upon the water at Averyville?

A. You mean in the way of making it pathogenic?

Q. In the way of making it pathogenic or in the way of affecting its sanitary condition?

A. 125 miles, I should think it would have a very limited effect if any.

Q. Would the sewage from the city of LaSalle have any effect?

A. I should think it might.

Q. Do you know how large LaSalle is?

A. No, I do not know the population.

Q. Well, isn't it essential?

11759 A. No, not so essential I think. If there were ten or twenty or fifty cases of typhooid fever there it would be more important than if the city had 2,000,000 inhabitants, and no typhoid.

Q. Do you mean to say that Chicago has no typhoid?

A. Not at all. It has a great deal of typhoid. Much too much.

Q. Then why do you undertake to eliminate Chicago, or a city of 2,000,000 of people with no typhoid?

A. Well, the position of LaSalle is not the same as Chicago.

MR. TODD: I submit that he has not eliminated Chicago as a city of two million with no typhoid.

THE WITNESS: I did not have Chicago in my mind.

MR. JEFFRIES: What did you have in your mind?

A. I didn't have any great population.

Q. Do you know of any city of two millions of people that don't have typhoid fever? As an epidemiologist, have you ever heard of a city of 2,000,000 of people that had no typhoid fever?

A. Cities of course like Berlin and Munich. They are very large cities, but they have very little.

Q. But they have typhoid fever?

A. Yes, a very little—very little.

Q. And that typhoid fever is reduced there because of 11760 the protection of their water supply, is it not?

A. It is.

Q. Do you know, doctor, the total population of the sewered cities upon the Illinois river above Averyville?

A. The total population of the cities?

Q. Yes.

A. No, I haven't them. I have looked them over, but I have not the data in my mind.

Q. Name the towns then?

A. Well, some of the principal towns would be Lockport and Joliet—

Q. Well, the sewered towns I mean.

A. I don't know about the physical conditions.

Q. Do you know whether LaSalle is a sewered town?

A. No, I do not.

Q. Would not that make a great difference?

A. It makes a difference whether sewage comes into the water or not.

Q. Does not it make a difference as to the manner in which it is discharged into the water, whether it runs through the earth, over the earth, deposited in private vaults or directly sewered into the river; isn't that important?

A. The more direct—

11761 Q. Is not the total population of the sewered towns and the information as to whether the towns are sewered necessary in order to enable you to determine the sanitary condition of the water below those towns?

A. I think it would be a desirable thing.

Q. As an epidemiologist do you mean to say doctor, that you will undertake to express an opinion as to the sanitary condition of the water at Averyville without having first, as an epidemiologist, examined the physical conditions of the country and the river above Averyville for the purpose of determining the number of people living upon the water-shed, the various towns located on the water-shed, and with reference to whether or not those towns and cities are sewered or not, and the amount of typhoid fever prevalent on the river?

A. I am here to give you any information that I can and if you care to give me other data to use with those I have, I should be glad to give you my further opinion on that.

Q. Well, what data have you?

A. I have data with regard to the clinical course and pathology of typhoid fever and malaria, and general knowledge of infectious and epidemic diseases.

Q. Now then, answer my previous question, doctor. Will you undertake to express an opinion, and why have you
11762 undertaken to express an opinion as to the sanitary condition of the water in the Illinois river at Averyville without having first examined the physical condition of the river above Averyville, and examined the towns and cities situated upon its water-shed, to determine whether or not they were sewered directly into the river, the number of people living in those towns, and cities, and also examined the typhoid fever statistics of those cities?

A. The opinion I have given you is based—

Q. And also examined as to whether or not they had any sewers at all?

A. The opinion I have given you is based upon the data I have.

Q. On the data that you had?

A. That I have.

Q. The clinical and biological?

A. And general, and the data that I have collected in various ways with regard to the conditions here, without going into certain of the points that you have mentioned.

Q. Now what data have you collected, doctor. I want to know what specific data you have collected, that would enable you to determine and express an opinion as an epide-
11763 miologist now, upon the sanitary condition of the water in the Illinois river at Averyville?

A. Well, I have collected a great deal of data upon the self-purification of streams. I have a good deal of general knowledge of bacteriology. I fear this is rather an immodest sort of a statement, but I must do it, as you asked me to.

Q That is all right. I want you to make it.

A. I have gradually accumulated general conceptions about water supplies and sanitation in the course of the last fifteen years in medical work. I have read some of the literature bearing upon the researches upon the conditions of the Illinois river. I have talked with friends before I had any idea of dealing with this case, with regard to the situation and have formed judgments upon the situation. From all those together, and from my general knowledge of disease, clinical and pathologic, mode and spread of typhoid; from the fact that I have received what I regard as reliable information concerning the existence of typhoid in cities below Chicago on the river, and that the sewage from some of those cities at least, in which typhoid fever exists, is poured into the river. On all these taken together I have formed my opinion.

Q. Do you know, doctor, whether there is a town on the
11764 Illionis river that uses the water of that river for drinking purposes or domestic purposes, between Chicago and Grafton?

A. I should hope that there was not any that did not filter or boil the water.

Q. Don't you know doctor, that they don't use it filtered or in any other way?

A. I am very glad to hear it.

Q. Well, do you know it, and did you know it?

A. No.

Q. Now doctor, you spoke of this general information that you had received with reference to conditions above Averyville. Please state what conditions you have found from your examination of those conditions?

A. Well, I have a map here that gives some information.

Q. What is that, doctor, that you are examining now?

A. This is a map of the Illinois river and its principal tributaries,——Journal of Experimental Medicine.

Q. One of Professor Jordan's papers, is it?

A. It accompanies one of his papers as an illustration.

Q. Gotten up by Professor Jordan?

A. I imagine it was copied from some map. I know he

would be sure to get a good map if he used one. I have
11765 also here the Rand-McNally map of Illinois, which I will
use if you prefer that I use it. This is a little more easily looked over. It would take too long to give you all the data that I have collected, that I stated———

Q. I want to know just exactly what you did get.

MR. TODD: Give all details.

A. Well, as I understand it, the Illinois river receives a number of tributaries, including the Desplaines river, and the Fox river and the Kankakee river and the Vermillion river, and the Sangamon river, and other streams of various sizes and that these streams come into the river of course at different points. I understand that before the drainage canal was constructed that sewage was pumped from the Chicago river into the Illinois and Michigan Canal—I think that is the name of it—and that that canal then emptied that sewage into the Illinois river, but that since the drainage canal was built the Chicago river is more directly connected, without the aid of the pumping station. The sewage is poured into the canal at the upper part of the river. I should know that there are three or four locks on the river; that the stream is not a rapidly flowing stream; that in many parts of the river the rapidity of flow is very slow. I have understood that it is as low as half a mile in some places,
and that the conditions of flow in the stream are different
11766 at different times of the year. I have been given to
understand that not all the sewage of the city of Chicago goes into the drainage canal at present. Part of it still goes into the lake, but that an intercepting sewer is being built to lead more of the sewage into the drainage canal. I understood that the current into the lake from the Chicago river before the drainage canal was built was a very slight one, and sometimes it almost tended to run the other way, and that the smell from the sewage became objectionable, to the city, and that it was believed that the pouring of the Chicago river and its sewage into the lake was a deteriment and menace to the city's health, and that the drainage canal was built in order to protect the city from this danger, and also from the nuisance. I understood that this cost a great deal of money, many millions of dollars,—more than thirty millions, perhaps of dollars, and I have learned that on the banks of the river there are a number of towns which I have

already mentioned. I learned that typhoid fever exists in at least some of those towns, and I have been told by men upon whose opinions I rely that the sewage from some of those towns in which typhoid exists, is poured into the Illinois river, and that there is no adequate protection to either the river bank or the banks of the tributaries of the river, from contamination;
11767 that in fact the whole Illinois river is a drainage canal—in one sense it might be regarded as a drainage canal, and a drainage canal that is polluted at a great many different places. Then I have learned that the sewage deposited into the drainage canal and in points below it, had decreased with great rapidity in the number of bacteria which it contains, and that of course that agrees with observations in other places under similar conditions.

I have learned further that the stream as far as chemical and bacteriological analyses permit of a judgment to be formed, purifies itself gradually on the way down, from Chicago to Peoria; that at Lockport and Joliet the contamination of the stream is still very great, probably still great from the city of Chicago, and at Morris there is still a good deal of contamination in the stream, but that from that point on there is a tolerably rapid, though gradual diminution in the contamination of the stream as judged by bacteriological and chemical studies of the stream; that when Ottawa is reached there is far less contamination than at Morris. At LaSalle the contamination is still less, and that at Henry it is very slight, whereas, at Averyville the conditions are those of an ordinary river water that
11768 would ordinarily be regarded as a fairly good water, but that suddenly, below Averyville, at Peoria, the river again becomes very badly polluted from the sewage of that city. Indeed, while at Averyville a few miles above Peoria, the stream is a tolerably pure river water, even under present conditions, at Wesley, which is just below Peoria, the conditions are practically as bad as they were at Lockport, only thirty miles from Chicago; that this condition is also very bad at Pekin, and in all probability is exagerated by the sewers poured into the river at Pekin, and below Wesley, the river again tends to purify itself, and at Havana there is a remarkable diminution in the phenomena which chemists and bacteriologists regard as polluting phenomena; and at Beardstown, still less, and at Kampsville, still less,

and when Grafton is reached, the conditions are very much again like those at Averyville, as far as chemical and bacteriological studies are concerned, and the river compares quite favorably with ordinary river waters.

Q. That is all the information you obtained, is it?

A. I have here the number of deaths from typhoid fever in some of the towns along the banks of this river. They have already been put in evidence.

Q. It is all hearsay with you, isn't it?

A. I have introduced no hearsay except that that I regard as reliable. 11769

Q. But it is in fact, all hearsay, is it not?

A. Hearsay and reading. If you call reading hearsay.

Q. In other words, doctor———

A. It is not personal investigation.

Q. And therefore is hearsay?

A. It comes through the eyes.

MR. TODD: I submit that that interpretation is not exactly correct because statistics and health reports and matters of that kind would not be characterized as hearsay in the strict sense.

GENERAL CROW: Well, when you repeat them it is clearly hearsay, when you go to repeat them. If you introduce that as original it is not, but he repeats what he has read and what people have told him.

MR. TODD: Well, we differ with you.

MR. JEFFRIES: You did not ascertain the population of Joliet, LaSalle, Ottawa and Morris?

A. I looked over the population of those places, but I confess, I cannot recall them.

Q. You don't know whether they were sewered towns, or whether they had any sewers emptying into the Illinois river or not, do you?

11770 A. I was told that some of them were sewered towns.

Were you told which ones were sewered?

A. No, I don't recall that I was.

Q. So you based your judgment as a bacteriologist upon just what you have stated here in evidence, and that is the only reason upon which you state that in your judgment the water at Averyville is safe for domestic and drinking purposes?

A. I have not given you the details of the experimental work which I have studied.

Q. Well, we understand that you did give us the details of your experimental work which you have studied elsewhere, and we also understand that you took that into consideration in passing judgment upon the sanitary condition of this water, doctor?

A. I have done no experimental work on this river myself.

Q. I understand, but you are insisting on taking into consideration the experimental work that you have done in hospitals and other places?

A. And what I have read, and the experiments of others.

Q. Then I understand you that from your experience as a bacteriologist and biologist, and from what you have read, and from what you have just stated with reference to the
11771 physical conditions in the Illinois river, as having been obtained by you in talking with others and in reading articles written by others, you as an epidemiologist, undertake to express an opinion that the water in the Illinois river at Averyville, after receiving the sewage of Chicago and of other cities situated upon that river above Averyville, is in a reasonably safe sanitary condition?

A. I do.

Q. And you think, doctor, that you have stated in evidence sufficient information to enable you to make that statement?

A. I do.

Q. Doctor, do you know how long it takes the water to travel from Chicago to Averyville?

A. No, I don't know the exact time.

Q. Do you know whether it takes as much as five days?

A. I should think it would take that much.

Q. Now in expressing an opinion as to the sanitary condition of the water at Averyville, and the effect of the Chicago sewage upon that water, is it not essential to take into consideration the stream flow, the velocity of the stream above Averyville and between Averyville and the point of the sewage discharges?

A. If you hadn't evidence that the water at Averyville
11772 were relatively pure in other ways, it would be desirable to have that fact too. It is desirable to have all information on all factors that you can get of course.

Q. Well, doctor, supposing that the bacterial analysis of the water in the Mississippi river at the chain of rocks disclosed certain bacterial counts, and that the analysis of the water of the Mississippi river at Jefferson Barracks, a distance of twelve to fifteen miles below the Eads Bridge, or the central portion of the city,—Jefferson Barracks, being below the sewage discharges of the city of St. Louis, and assuming that the bacterial counts observed and obtained in the analysis of the water at Jefferson Barracks, was not materially different from those obtained at the chain of rocks, and assuming that the water at the chain of rocks was fairly safe for domestic purposes, what in your judgment would be the sanitary condition of the water in the river at Jefferson Barracks, and what would be the sanitary significance of the similarity of bacterial counts in the samples of water examined from the two points, the sewage of the city of St. Louis, containing 600,000 people, having been discharged into the Mississippi river from seven to fifteen miles above Jefferson Barracks, and the point thereat where samples were taken?

A. Assuming all the things that have been assumed, the
11773 proximity of Jefferson Barracks to the sewage out-pour
from the city of St. Louis, would even then render the water suspicious, I should think.

Q. Now then, what effect, doctor, has proximity to the place of the source of pollution upon the sanitary condition of water at a given point?

A. Well, given a certain rate of flow, and then the nearer the place to the source of pollution the less the opportunity for self-purification.

Q. Then you mean by that that because of the flow the impurities discharged into the river are carried by the current and by the volume of water down the river below the point of discharge, is that true?

A. Yes, that would be true.

Q. And the greater the volume of the water, the more rapid the current, the greater the zone of pollution will become and exist in the river; is that true?

A Yes, I think that is true, although the dilution would have an important——the greater the dilution the less the pollution at the point where the dilution takes place, of course.

Q. But the pollution is there nevertheless?

A. Yes.

11774 Q. Although in a more diluted state?

A. Yes, and in a given quantity of water it would be less dangerous than undiluted.

Q. But by reason of the greater quantity of water mixed with the same quantity of sewage, the zone of pollution is more extensive as the water flows down the stream?

A. That would depend of course upon the quantity of dilution. I don't know of my knowledge that the extent of pollution and longevity of pathogenic bacteria is directly proportionate to the volume of water. I imagine it is not.

Q. Doctor, assuming that the bacterial counts at Averyille were from 33 to 100 per cent greater in the analyses of the water in the Illinois river at Averyville made prior to the opening of the Chicago drainage canal, than is contained and found in the analysis of the same water or the water from the same river since the opening of the canal; what significance do you attribute or would you attribute to the relative differences in bacterial counts?

A. I think the significance would depend largely upon the volume of water passing through as compared at the two times.

Q. Well, would it have any significance at all?

A. It might not.

Q. Under what conditions would it not?

11775 A. If there were no pathogenic bacteria among them, it would not be significant.

Q. Well, now assuming that there were pathogenic bacteria deposited in the river at Chicago in both instances?

A. No, but I mean at Averyville.

Q. Assuming that the sewage from Chicago passed down the Illinois river prior to the opening of the canal and that since the opening of the canal the same sewage passes down the river, or the sewage from the same city, diluted with 250,000 cubic feet of water per minute, and assuming further that the bacterial counts were from 33 to 100 per cent more at Averyville prior to the opening of the canal, than they are at Averyville since the opening of the canal, what significance would you give that?

A. It might not have any significance.

Q. Why not?

A. And especially unless the counts were made at different times of the same day, and at every day, for a very long period of time.

Q. Well, assuming that that condition existed, with the counts having been made and the analyses having been made of the waters at both periods, for some two to three months, continuously, once or twice a week, and that the average
11776 conditions were as assumed in the previous question?

A. And the bacteria were less numerous?

Q. Yes, since the opening of the canal than prior thereto?

A. Do you mean that the total number of bacteria or the bacteria per cubic centimeter?

Q. The total number of bacteria per cubic centimeter obtained from the samples of water analyzed bacterially?

A. Well, I think it would depend largely upon the volume of water.

Q. Isn't it a fact doctor, that the addition of the 250,000 cubic feet of water per minute to the Illinois river, mixed with the sewage of Chicago, has had a tendency to preserve the life of the pathogenic germs, and carry them much further down the Illinois river than they were carried prior to the opening of the canal when they were discharged into that river without being mixed with the water from Lake Michigan?

A. I don't think that it can be regarded as a fact; I don't think such a fact has been established.

Q. Assuming that it was established, isn't it a fact that the pathogenic bacteria would disappear much more rapidly in the smaller stream containing the same sewage than it would in the larger stream containing the same sewage?

11777 A. I am not sure that it would. I don't know that the percentage comparisons are so different as to make any material difference in the rapidity of death.

Q. Well, what are you sure of?

A. Of things I am convinced of.

Q. Well, do you say that it would make no difference?

A. No, I say I do not know.

Q. You do not know whether it would or not?

A. No.

Q. Didn't I understand you to say yesterday that the more water you add to sewage, the longer the pathogenic germs contained in that sewage, so mixed with the water, would live?

A. I said that the typhoid bacilli would live longer in pure water than in sewage contaminated water.

Q. Didn't I understand you doctor, to say yesterday that in sewage polluted water, water strongly impregnated with sewage, there would be greater saprophytic action, and consequently a greater reduction of the pathogenic bacteria, and that in proportion to the added volume of water to the sewage, the saprophytic action was decreased, and the life of the typhoid and other pathogenic bacteria prolonged.

A. I don't think that I said in proportion, and if I did, I
11778 should not have said so.

Q. Well, if it is a fact that dilution does increase the life and longevity of the typhoid and other pathogenic germs, isn't it a fact that it can be proportioned?

A. Not until the fact is established.

Q. By the establishment of the fact?

A. By actual experiments, and actual knowledge, and as far as I know that has not been established.

Q. Well, would it not be necessary to establish that in order to make the determination?

A. It may not be very easy to establish it.

Q. As a bacteriologist, what effect has the discharge of 250,000 cubic feet of water per minute into the drainage canal, had upon the bacterial action of the sewage of Chicago when discharged into that canal?

A. Well, I am not testifying as a bacteriologist, but rather as an epidemiologist and pathologist. My opinion with regard to that would be based entirely upon actual observations, as far as possible, and without actual data, though, I think that would be unwise, to give a very definite opinion. I think it might be different in the two streams.

Q. Has it had any effect?

A. I should think it probably had.

11779 Q. It has had the effect, has it not, of prolonging the life of the typhoid germ?

A. I don't know that it has.

Q. Well, if it has had any effect that would be the effect, would it not?

A. Yes, I should think that would be the effect if it had any effect.

Q. Does your experience and your information furnish you any support or any aid in forming any opinion?

A. My opinion is formed on the data that I have given you.

Q. I will ask you, Doctor, if it is not a fact that by the discharge of the sewage of Chicago into the Desplaines and Illinois rivers, without being mixed with water from Lake Michigan to any extent whatever that the conditions for the disappearance of the pathogenic germs would be far greater and they would much more rapidly disappear under such conditions than they will by being discharged into the Illinois river as now, mixed with the water from Lake Michigan at the rate of 250,000 cubic feet per minute?

A. I don't know that to be a fact.

Q. Well, what is your opinion?

A. My opinion is that there is probably very little difference.

11780 Q. Then you are of a different opinion from what you were yesterday when you testified?

A. No, I don't think so.

Q. Then you think the addition of the volume of water would not be conducive to the destruction nor would it be conducive to the preservation of the life of the typhoid and other pathogenic bacteria,—the addition of the 250,000 cubic feet of water per minute?

A. I am not sure that the quantity of water mentioned, as mixed would make any very great difference either way, but I think the tendency would be to increase the life of certain bacteria.

Q. I will ask you, Doctor, if the quantity of 250,000 cubic feet per minute, running 24 hours per day, passing through the same channel that the sewage of Chicago is passing, would not have a very great influence upon the activity of the saprophytic bacteria?

A. With the amount of sewage that there is, I could not be sure that that is true; it would have some influence undoubtedly, but how much, I don't know.

Q. Then, Doctor, I suppose you take the position that as it

would have no practical effect, that the drainage canal as
11781 it exists today, composed of the sewage from Chicago
and Lake Michigan water, is an open sewer?

A. I have not said that it had no practical effect.

Q. What effect has the water from Lake Michigan, coming at the rate of 250,000 cubic feet per minute through the canal, had upon the saprophytic activity of that water when mixed with the sewage from Chicago?

A. I have made no experiments to determine that question.

Q. Well, what is your opinion?

A. Without experimental data behind it?

Q. As an epidemiologist, that proposition is presented to you now?

A. As an epidemiologist I don't think that the opinion would be valuable.

Q. Well, what is your opinion, we will see whether it is valuable or not?

A. I have not any very confirmed opinion about it.

Q. Now, is that opinion equally true at Averyville?

A. The opinion about the purification?

Q. Yes?

A. I am of very much the firmer opinion about the conditions at Averyville.

Q. And why?

11782 A. Because the data that I have about Averyville are
such as to permit me to form an opinion.

Q. You mean to say that you have data about Averyville and yet no data about conditions existing in the drainage canal, and at the same time are willing to express an opinion upon the one and not upon the other?

A. I have data about both but the opinion is about two entirely different things.

Q. You say that you have no data upon the conditions existing in the drainage canal?

A. No, I said that the data I had were not sufficient to let me form an opinion about the particular question that you ask.

Q. Is the data sufficient to let you form an opinion as to the saprophytic action in the water at Averyville?

A. I said that from the distance that Averyville lies from

Chicago, that I doubted if there would be any appreciable difference at that distance.

Q. And in that opinion you have taken into consideration the question of distance then?

A. Yes.

Q. And distance alone?

11783 A. Distance and bacteriological and chemical analyses.

Q. You mean time instead of distance?

A. I mean taking into account all of the information that I have, as given to you this forenoon.

Q. Do you think that you have sufficient information to form an opinion and to recommend to a large city which is calling upon you for an opinion as to the sanitary condition of the water at Averyville, for the purpose of constructing a waterworks, and supplying that city with water, that the information that you have would enable you to say to that city that the water at Averyville is in a sanitary condition and reasonably safe, and is not affected by the sewage from Chicago?

A. I have sufficient information to say that in all probability it is reasonably safe, but that tests should be applied, before it should be recommended.

Q. Would you recommend to a city the use of the water in the Illinois river at Averyville, and would you in your recommendation state to that city that the water at that point was not affected by the sewage of Chicago as it exists today?

A. As I have said before, I would not recommend any river water for use in cities.

11784 Q. Would you recommend to that city that the water in the Illinois river at Averyville was not affected by the sewage of Chicago?

A. I would say that in my opinion it was not materially affected.

Q. And would you recommend to them that they could use it without fear of receiving any harmful results from Chicago; is that true?

A. As I have said, I would not recommend any water without tests.

Q. Well, you have not tested the water at Averyville, have you?

A. No.

Q. And yet you stated in your examination in chief that at that point it was reasonably safe, and that you would recommend it?

A. No, not that I would recommend it.

MR. TODD: I submit that all through his examination while he has given his opinion as to the waters of the Illinois river at certain points as being reasonably safe, at no point has he stated that he would recommend the water of the Illinois or any other river which receives sewage, for domestic and drinking purposes, without making preliminary tests, or the use of a filter system.

11785 MR. JEFFRIES: Doctor, if you knew that it did not take the water five days to come from Chicago to Averyville, would that have any effect upon your opinion?

A. Yes, it would.

Q. What way would it affect it?

A. I shouldn't be sure that in five days absolutely every typhoid bacillus would be dead.

Q. Doctor, if you were called upon to recommend that water at Grafton from the Illinois river, pass your judgment as an epidemiologist upon the sanitary condition of the water at Grafton for domestic use, and assuming that some city had called upon you to render an opinion as a scientist and as an epidemiologist, as to the sanitary condition of the water in the Illinois river at Grafton, with the information that you have, knowing that the city of Chicago is situated upon that watershed, or that the sewage of Chicago rather was discharged into the river, knowing also that the city of Chicago had a population of two millions of people, would you say to that city that the water at Grafton was not affected by the sewage of the city of Chicago?

A. I would say that in my opinion there was no evidence that is was.

Q. And that opinion would be of sufficient strength to 11786 enable you to say to the people, "You may use it without deleterious effects?"

A. I would advise them not to use it without filtration or boiling.

Q. And you would do that regardless of the fact that they were calling upon you to pass upon no question other than the effect of the sewage of Chicago upon the waters of the Illinois river at Grafton?

A. Yes, because you could never be sure of the protection between any two places.

Q. That is not the question, Doctor. A city calls upon you to give them an opinion as an epidemiologist, as to whether or not the sewage of the city of Chicago will affect the water in the Illinois river at Grafton; now, I want to know if in your opinion you could recommend to that city that the water at Grafton was in no wise affected at any time in the year by the sewage of Chicago?

MR. TODD: I object to the question for the reason that it does not take into account the conditions of pollution from the different towns upon the tributaries entering into the Illinois river, but asks for an opinion as to the sewage from Chicago without including the other conditions which obtain upon the river and are proper for consideration.

11787 MR. JEFFRIES: I suggest to the Court that counsel for defendants in his examination in chief, asked this witness his opinion as to the effect of the sewage of Chicago upon the waters of the Illinois river at Grafton, and that this question is directly in line with the question propounded to the witness in his examination in chief.

Q. (Question repeated.)

A. I would give them that as my opinion.

Q. You would?

A. Yes.

Q. Now, Doctor, what would that opinion be based upon?

A. Upon the information which I have obtained.

Q. That you have?

A. I have obtained,—and of course if I were asked in a case of that sort, I should get all the additional information I could about it.

Q. But remember, you have been asked that question with just what information you have, and no more, and you have not called upon either the defendants or the complainant in this case for additional information before you answered the question: you are answering it now upon just the information that you possess today, and do you still say that you would recommend it?

11788 MR. TODD: I object. He hasn't stated that.

GENERAL CROW: Let him state what he has stated.

MR. JEFFRIES: He has stated that it would have no effect.

THE WITNESS: In my opinion.

MR. TODD: Your question embraces two propositions; one was whether his opinion was that it was safe, and whether he would recommend it. His answer was that his opinion was that it was safe, but that he would not recommend it without further consideration.

MR. JEFFRIES: The answer to the last question as I understood you, Doctor, was that you would recommend that city as your opinion,—or rather would recommend to that city as your opinion, that the water at Grafton was in no wise affected by the sewage of Chicago.

A. Why, I would simply recommend that as my opinion.

Q. Your recommendation would be nothing more than your opinion, would it?

A. I would not put myself in the position of recommending my opinion. I would give my opinion.

Q. Well, of stating your opinion then?

A. Yes, that is all right.

Q. Now, Doctor, would you recommend that water, if 11789 you knew that the literature which you had been reading, stated that the germs of typhoid fever would live in running water and in sewage, and in sewage polluted water from five to thirty days, when you knew that the mean time from one end of the year to the other was eighteen and a half days from Chicago to St. Louis, and that a larger part of the year it was less than fifteen days, and at times less than ten days, would that have any effect upon your opinion, or upon you in expressing an opinion?

A. I would not recommend the water under any circumstances.

Q. Well, would that have any effect upon you in giving your opinion in making the recommendation which you said you would make, that the sewage of Chicago had no effect upon the water at Grafton?

MR. TODD: I submit that the words "recommendation" and "opinion" should not be confounded, as the witness has stated repeatedly what he would give as his opinion and what he would not recommend, and as the use of these words interchangeably creates confusion.

MR. JEFFRIES: Would you recommend, Doctor, that the water at Grafton was unaffected by the sewage of Chicago, knowing that the rate of flow from Chicago to the city of St. Louis was in the mean, eighteen and a half days; that
11790 during a greater part of the year it is less than fifteen, and oftentimes less than ten days, and knowing at the same time that the current literature of epidemiologists and bacteriologists, as they have observed the life and character of the typhoid bacillus, is from five to thirty days or more, and that it had not been accurately determined as to exactly how long they would live; knowing all those things, would that have any effect upon you in forming your opinion as to whether or not the water at Grafton was affected by the sewage of Chicago?

A. All information that I can gather, or could gather, would have an effect upon the formation of my opinion, and upon the information that I received, I would be willing to state it as my opinion that the water at Grafton is probably safe, as far as the city of Chicago is concerned,—as far as the sewage of the city of Chicago is concerned, but I would not recommend its use.

Q. Because why?

A. Because I do not recommend any river water for use.

Q. But, Doctor, if you were told that the water came from Chicago to St. Louis on an average of eighteen and a half days, and that it oftentimes came in less than fifteen days, and sometimes in less than ten days, would those facts have any tendency to change your opinion?

11791 MR. TODD: I object to the question for the reason that in the rate less than ten days, the height of the water is not included, the amount of area of inundated land in the valley of the Illinois river is not stated, and for the further reason that all conditions that actually obtain under the conditions of time flow, are not included.

Q. MR. JEFFRIES: (Question repeated).

A. In answer to that I would say that considering those facts if they were assumed to be facts, in connection with all the other conditions, they would not change my opinion.

Q. They would not?

A. Would not change my opinion.

Q. Well, if the water came from Chicago to St. Louis in ten days, and the sewage of Chicago was turned into the canal, and was typhoid infected, would you say that the water would be safe at Grafton or at St. Louis?

MR. TODD: I object to that question for the same reasons stated in the previous objection.

A. Considering all the conditions of the river, I would state it as my opinion that as far as the typhoid bacilli coming from Chicago are concerned, Grafton and St. Louis would not be menaced.

Q. When it comes within ten days?

11792 A. If it comes within ten days, with all the conditions of the river such as we know them, I should not regard the city as menaced.

Q. Do you mean by that, Doctor, that in your opinion the typhoid germs would not come from Chicago to St. Louis in the ten days, with the water?

A. Under all the conditions of the river, I do not think that they would.

Q. Would they under any conditions come?

A. To St. Louis?

Q. Yes?

A. No conditions that will ever be realized in my opinion.

Q. What conditions would there be under which they would come?

A. I think if you had a sterilized tube of distilled water leading from Chicago to St. Louis, coming down there in ten days, you could carry live typhoid bacilli from one city to the other.

Q. And they would come in no other way?

A. No, I would not say that.

Q. Would they come as far as Averyville?

A. Do you mean in ten days?

Q. In five days or ten days?

11793 A. Under the present conditions of the river?

Q. Yes?

A. In my opinion they would not.

Q. They would not?

A. No.

Q. Doctor, if a typhoid bacillus will die out in a running stream in five days, why has it become necessary for the large cities to build large filtration plants to protect their water supply, and why is it that the discharge of the sewage into the river has had such a grave effect upon the sanitary condition of the water in the river?

A. I have not said that the typhoid bacilli would always die out in five days in running river water.

Q. You said they would die out if it didn't take the water longer than five days to come to Averyville?

A. I said that in my opinion under the special conditions that exist in the upper part of the Illinois river and Desplaines river and the Chicago drainage canal.

Q. Well, what are those special conditions?

A. I have referred to them in my evidence of this morning.

Q. Doctor, didn't you tell me a few moments ago that you could not tell what effect the water of Lake Michigan had upon the saprophytic action in the water and the sewage of Chicago? 11794

A. I said that I could not state exactly what effect.

Q. And you cannot tell what effect it has from Chicago on down to Averyville, can you, so far as the pathogenic germs are concerned?

A. I cannot be absolutely sure of it.

Q. Can you be absolutely sure of it at Grafton?

A. Why, in my opinion it would have no appreciable effect at that distance.

Q. Would it have any appreciable effect at Averyville?

A. I don't know.

Q. What do you mean by appreciable effect?

A. Anything estimable by our present methods.

Q. In other words, you cannot determine typhoid anyway, can you, in the water?

A. I can determine it by the biological test.

Q. And that is all?

A. Yes.

Q. And, Doctor, isn't that all that you know about it; just simply what you could get from studying the biology of the disease in the patient?

A. I have given you whatever information I can in an-
11795 swer to your questions.

Q. Isn't that biological test the only test that you could rely upon at Averyville?

A. It is the best of all the tests. There are other axercerviate tests that are extremely valuable for throwing light upon the mode—

Q. Well, if there are other tests that you can rely on, why don't you say what those tests are and limit it to those tests? In other words, I have been trying to find out by what tests you can determine the sanitary condition of water.

MR. TODD: I object; the witness is not called upon to limit his tests.

MR. JEFFRIES: He has evaded it every time.

MR. TODD: I submit that his answers stand in the record, and the Court will say whether he has evaded it or not.

Q. (Question repeated.)

A. As an epidemiologist one utilizes all information he can, and all kinds of tests that are applicable and he bases his opinion—

MR. JEFFRIES: And the biological test is the best test?

A. In my opinion it is the most important.

Q. Did you have the biological test at Averyville?

A. It was impossible to apply it there.

11796 Q. Now, then, what experience have you had with any other test than the biological test?

A. No personal experience.

Q. Do you know of anybody else that has made any test biologically at Averyville?

A. As far as the city of Chicago is concerned, that cannot be applied.

Q. Cannot be applied in what way?

A. To Averyville, for if typhoid exists in Averyville, there would be no evidence that it came from Chicago necessarily.

Q. Not unless they used the water.

A. Nor even then, it would not, on account of the contamination between Chicago and Averyville.

Q. In your opinion, though, it would have no effect upon them even if they did use the water?

A. In my opinion it would be reasonably safe.

Q. Although the water came down there in less than five days?

A. Less than five days.

Q. Doctor, I will ask you this question: If you do not know that the Lawrence typhoid epidemic it was shown that germs passed through a reservoir holding fourteen days' water supply for the city of Lawrence?

A. The conditions are very different.

11797 Q. Specify the difference in the conditions.

A. As I understand it, the reservoirs contained water such as is used for drinking purposes, whereas, the typhoid bacilli coming from Chicago toward Averyville are subjected to the tremendous influences of the sewage in the drainage canal.

Q. Doctor, didn't you tell me that you had no means of ascertaining just what effect the addition of 250,000 cubic feet of water coming from Lake Michigan, had upon the saprophytic influences of the sewage?

A. I said that I had no way of measuring the exact effect.

Q. And it might increase the saprophytic influences, and it might decrease them, is that right?

A. I have forgotten just how I answered the question, but I think I said, at any rate, I think now, that without definite data it would not be wise to express an opinion on an increase or decrease.

Q. Well, unless you can ascertain what effect that additional water has had upon the sewage of Chicago, how is it, doctor, that you can form an opinion as to the sanitary condition of that water at any point below the discharge of the Chicago sewage?

A. Because the evidence that I have gathered thus far indicates a high degree of purification in the upper part

11798 of the Illinois river approaching Averyville.

Q. Well, that is not the question.

(Question read.)

MR. TODD: I submit that the answer is responsive to the question.

MR. JEFFRIES: I will ask you this question, doctor: did you not state yesterday that the saprophytic activity in the sewage was far greater than it is in the sewage polluted water?

A. I do not recall that I did.

Q. Well, is it so?

A. I think it would all depend upon the percentage composition relations of the sewage, their differences in proportions.

Q. I will ask you this question: What is the difference, doctor, between the saprophytic activity or action in the sewage that is discharged at the mouth of the sewer into the river, and the saprophytic activity of the contents of the canal itself, after the sewage has been discharged into it?

A. I don't know that the dilution is great enough to make any difference.

Q. You don't know that it is?

A. No.

11799 Q. But you have no information upon that subject?

A. I have not.

Q. Doctor, how many of the typhoid germs that come from the sewers of Chicago are dead before they go over the Beartrap Dam?

A. I don't know the exact position of the Beartrap Dam.

MR. TODD: That is located at Lockport; that is the end of the canal.

A. How many of them are destroyed?

Q. Yes?

A. I haven't any idea.

Q. Well, what percentage of them?

A. How long does it take? Can you tell me how long it takes? I don't know how long it takes to go that distance.

Q. Well, assuming that it takes 24 hours?

A. Well, I should think a great many were killed.

Q. Well, what percentage?

A. I don't know.

Q. Would it be ten or ninety?

A. I am not prepared to offer an opinion on that at all.

Q. Well, by the time they get to Joliet, what percentage of them would be killed, or would be dead, do you know?

A. I don't think one could answer a question like that.

Q. What percentage of them would be killed by the
11800 time they get to LaSalle?

A. Could you give me the time relation?

Q. Well, we will say two days,—two and one-half days.

A. I should think a very great many more.

Q. Well, what percentage of them?

A. I could not give you a percentage.

Q. Could you tell what percentage would be dead by the time they got to Averyville?

A. I should think that probably they would all be dead at that time.

Q. That is just a think upon your part?

A. It is my opinion based upon my studies and information.

Q. What did you study upon the life of the typhoid germ?

A. I have given you the source of my information, this morning.

Q. Is there any authority, doctor, within your knowledge, that says that or that holds that the sewage of the city of two millions of people discharge into a running stream, will disappear within five days?

A. There is evidence that at any rate the majority of typhoid bacilli will.

Q. Where is the evidence? Name your authority.

A. Well, from experimental work that has been done.

11801 Q. Where?

A. In Chicago.

Q. Where?

A. In connection with the drainage canal.

Q. Anywhere else?

A. Not that I know of.

Q. Well, now, don't you know that there has been no such examination and experiments made in the water of the drainage canal?

A. Experiments on the life of the typhoid bacillus?

Q. Yes, where it was limited to five days?

A. I have not said that the life is limited to five days.

Q. Well, where is the evidence doctor, that it was limited to five days?

A. I have not said that there is evidence that it was limited to five days.

Q. Well then, if you have no evidence limiting it to five days, how is it that you can say that the water at Averyville has purified itself of typhoid bacteria and other pathogenic germs, when the water comes to Averyville within five days and purification being one hundred per cent, while coming from Chicago to Averyville?

A. The evidence drawn from all the sources that I have 11802 mentioned makes me have that opinion.

Q. Now doctor, coming back, will you give me one author, a reputable, scientific bacteriologist who has stated editorially that the life of the typhoid germ in sewage is limited to five days?

A. I haven't any references. I don't know that it occurs in literature.

Q. Does it not occur in literature editorially stated by men who have made the actual experiments of the life of the typhoid germ in sewage, that it would live longer than five days in that sewage?

A. That might be true.

Q. Then is there any reason why, doctor, if it will live in the sewage five days, that it will not live in the Illinois river and in the drainage canal five days?

A. Yes, I think the conditions are very different again.

Q. What are the conditions that have changed,—what changed conditions?

A. The conditions of sedimentation are very different for one thing.

Q. Does that affect the life of the germ, and do you mean to say that typhoid fever germs deposited in a running stream will disappear in the course of sedimentation entirely, in five days?

A. I have not said so.

11803 Q. Well, do you not inferentially say so when you say that they have all disappeared by the time the water gets to Averyville, and give sedimentation as the cause?

A. I have not said that they all disappeared at Averyville.

Q. Did you not say it was 100 per cent removed?

A. I did not.

Q. You said it was safe?

A. I said that I regarded it, in my opinion, that it was reasonably safe but that I would not recommend it for use.

Q. Then they all ought to be practically removed before you would recommend it?

A. I think so.

Q. But you would not say that they were all removed by sedimentation, would you?

A. No, I would not say so.

Q. Would you say that they had all been removed by death?

A. I would say that in my opinion, in all probability, the water would be reasonably safe at Averyville.

Q. What do you mean by reasonably safe?

A. As safe as most water supplies in this country.

Q. Knowing that there was a city of 2,000,000 people with
the sewage of that city discharged into the river 150 miles
11804 above and the water coming down there in five days, and
still would you say it was reasonably safe?

A. As reasonably safe as many of the water supplies in this country, as far as that particular factor is concerned, of course.

Q. Would it be reasonably safe for domestic use?

A. As reasonably safe, in my opinion as many of the supply systems.

Q. Well, what water supply?

A. Well the water supply of the city of Philadelphia, for example.

Q. Is not the water of Philadelphia a notoriously bad water supply?

A. It is about the same water supply apparently, about as bad as the city of St. Louis.

Q. Is it not much worse than the city of St. Louis, and isn't it notoriously so?

A. The mortality from typhoid is just about the same.

Q. Well, give the rate?

A. The mortality from typhoid in Philadelphia is about 33 per 100,000.

GENERAL CROW: For what year?

11805 A. I cannot give you the exact year, but the year that
I estimated it.

MR. JEFFRIES: And what is it for St. Louis?

A. Not more than 34.

Q. That is according to your figures?

A. According to the figures of the St. Louis Health Reports.

Q. According to your figures, that you figure there, and get from the St. Louis Health report?

A. According to the figures of the St. Louis Health Report which I have here.

Q. Do you mean the figures as grouped by you or as put up originally by the St. Louis Health report?

A. I mean the figures on page 424 of the 24th Annual Report of St. Louis.

Q. Is it the figures that they class as typhoid or the figures that you class as typhoid?

A. Figures that they class as typhoid for the year 1901.

Q. Now doctor, I want to know if in your opinion, or if I understand you to say that in your opinion the water at Averyville is safe for domestic and drinking purposes, after the sewage of Chicago, of 2,000,000 of people have been discharged into it, through the drainage canal?

11806 A. I have not said so. I said that in my opinion it is reasonably safe.

Q. Well, is it safe?

A. No.

Q. Is the Chicago sewage an element of danger?

A. In my opinion it is not.

Q. At any season of the year?

A. So far as my information goes, my opinion is that it is not.

Q. And you are applying the information that you have to all seasons of the year—summer and winter?

A. Yes.

Q. Is that true?

A. Yes sir.

Q. Now then, what causes the removal of the pathogenic germs from that river, that are deposited in it by the sewage of Chicago?

A. The same things which are concerned in the removal of pathogenic bacteria from sewage contaminated river water in general and which I have designated in my evidence heretofore.

Q. Now then, state what evidence, what that is. In other words, is it sedimentation or is it the effect of the sewage upon the pathogenic germs themselves?

11807 A. I gave it as my opinion that the principal influences concerned were the effect of saprophytic bacteria, the effect of sedimentation, and the processes that go along with sedimentation, and the effects upon the food, nutrient supply. Of course there are many other influences.

Q. What do you mean by the food nutrient supply?

A. I mean the food supply of pathogenic bacteria.

Q. Do you know that the typhoid bacilli require to feed upon anything when found in sewage and in running water?

A. It is my opinion that they do.

Q. Don't you know that it is the opinion of the best bacteriologists that they do not feed upon anything unless the media is of sufficient temperature to permit their multiplication?

A. That might be true.

Q. Isn't that true?

A. They have a right to their opinions.

Q. And you are of the reverse opinion although you have made no bacterial analyses or experiments with reference to the life and growth of typhoid germs?

A. I have not said that I was of the reverse opinion.

Q. Well, are you of that opinion?

A. I am of the opinion that the typhoid bacillus, while it lives, is undergoing changes all the time, and that where 11808 there is a destructive metabolism there must be also some catabolism.

Q. Is that true when they lie dormant in ice?

A. I think there would be some change. I doubt if they could lie absolutely dormant. Where there is life there is change.

Q. But as to the extent of that change either in ice or in the water, you know nothing about it?

A. I know very little about it.

Q. You know they do live in ice for three months?

A. I know they live in ice a long time.

Q. And you know that they live in river water a long time?

A. And they live in distilled water longer.

Q. Which is the greatest factor of the removal of typhoid and other pathogenic germs in the Illinois river water, the action of the saprophytes or sedimentation?

A. I would put the two together, as the most important influences.

Q. Well, of the two which is the more important?

A. I don't know.

Q. Isn't it true that there is no sedimentation occurs in the river at the time of high water, and isn't it true also that as the current flows, with the continuous current, that sedimentation is a very small factor?

A. In my opinion it would always be an important factor. 11809

Q. Even when there is a scouring action?

A. The scouring action would not be uniform over a great distance, in my opinion.

Q. It would be constant over a great distance, would it not?

A. Constant in degree?

Q. Yes?

A. I should think not.

Q. Well, it would be continuous then?

A. It might not be.

Q. Well, the scouring action to a large extent would follow the rise in the river, would it not?

A. That would depend very largely upon the geological conditions.

Q. Don't you know from the amount of sediment that is carried in the river, that scouring action must take place?

A. Some scouring action I have no doubt.

Q. At all times?

A. I have no doubt that it does at times, but my opinion is that parts of the river have a very clean bottom instead of having the sort of bottom that one expects where much sewage is being carried down.

Q. And that is accounted for by reason of the fact that it is continually scouring out?

11810 A. Not at all. By the fact that it is destroyed before it gets to these places.

Q. How about the mineral matters that are washed in?

A. Where do they come from?

Q. Where do they go to? Are they not scoured out?

A. They are gradually carried down.

Q. Isn't that what makes the turbidity of the water, and goes to make up the total solids in the chemical analysis?

A. A large part of the turbidity is due to the plankton and not to mineral material.

Q. Isn't that true, that a large part of these total solids found in the chemical analysis, is due to the carrying down by the current of the polluted matter, that is deposited in the river above, whether it be mineral earth or vegetable, or what not?

A. In many analyses and in certain portions of the river at certain times, that is true; at other times it is not true.

Q. At what times would it not be true?

A. When there is less floating matter in the water.

Q. Assume that a small particle of clay equal in size to the typhoid bacillus, should start from Chicago and come down to the Mississippi river at Grafton, how would its behavior compare with the typhoid bacillus coming, and what effect
11811 would sedimentation have upon it?

A. Why, it would not be exposed, or though exposed to similar influences, its reaction would be totally different on account of its chemical constitution.

Q. Well, assume that its settling action would be the same?

A. That its settling action would be the same?

Q. Yes, the action of sedimentation, or its conduct concerning sedimentation would be the same?

A. What would be the difference in the results?

Q. Yes.

A. It would not be easily acted upon by the chemical influences on account of its chemical constitution, while the typhoid bacillus would.

Q. Well, do you think those mineral matters, such as small particles of clay and dirt, would come down from Chicago to St. Louis?

A. I don't know how far they would be carried. I have never looked into that, but I know that materials are carried by rivers down to the mouths.

Q. As an epidemiologist, have you ever studied the question of sedimentation?

A. By personal experiment, no.

11812 Q. By personal observation of rivers?

A. No.

Q. What have you studied in connection with sedimentation, as applied to epidemiology?

A. Only the observation of sedimentation in cultures in the laboratory, and literature bearing upon the subject.

Q. What literature have you studied?

A. The literature of the ordinary text-books, a long time ago.

Q. You have not studied it recently?

A. No.

Q. How long has it been since you have studied it, doctor?

A. Oh, I have not studied it since 1895.

Q. That was before you came to Chicago?

A. Yes.

Q. And while you were in Baltimore?

A. Yes.

Q. And then only in the school room, in the class room?

A. Well, in the laboratory, and in my work rooms, yes.

Q. Do you remember what you studied?

A. No, the ordinary text-books. I am not an authority on sedimentation.

Q. Did you ever write any article upon sedimentation?

11813 A. None, I have no special --

Q. Did you ever write an article upon any other subject connected with the sanitary conditions of water, and water supplies?

A. No.

Q. Did you ever make a report as to the sanitary conditions of any water?

A. No, except in connection with the cerebral spinal meningitis epidemic at Loona county. We pointed out the mode of pollution of the town by water running down from the streams on the side of the hill.

Q. I understood you to say that it was not accurately determined what was the source of that epidemic?

A. No, it certainly was not from the water in my opinion.

Q. So you made a report that it was not a water-borne disease?

A. No, we made quite an elaborate report about it; but we referred to the water current in the streets and sewage, and contamination of water running down into the streets, as one of the unwholesome influences.

Q. I understood you to say doctor, that you never made any chemical analyses?

11814 Of a river water. I have made of course, many chemical analyses, but not of river water.

Q. And no bacterial analyses?

A. No, not of river water.

Q. And you have never made any report of the water supply or sewage disposal involving the expenditure of money, have you?

A. No.

Q. Have you ever taught hygiene or sanitary science?

A. Only in connection with other subjects; not as a subject by itself.

Q. Did you ever teach sanitary science?

A. I teach it every day in a general way, but not under that heading.

Q. Under what heading do you teach it?

A. Under the heading of personal and individual hygiene.

Q. But not municipal hygiene?

A. No, I know nothing about it.

Q. And you have never written a book on any of the subjects connected with water supplies or sewage discharges, or disposals?

A. No.

Q. Have you ever contributed anything to the science of sanitation in reference to the supply of water?

11815 A. Any literature?

Q. Yes?

A. Have I published anything on water supplies?

Q. Yes?

A. No, nothing.

Q. Doctor, I understood you to say in your direct examination that you limited the life of the typhoid germ from five to seven days. Am I correct in that?

A. No.

Q. Now, then, have you any idea—

A. I said that in sewage contaminated water, it was my opinion that the majority of typhoid bacilli died before from five to seven days.

Q. Well, that is not a very large reduction, is it, a majority in from five to seven days?

A. It is a reduction of more than fifty per cent.

Q. Well, assuming that there were millions and millions, discharged into the sewers of Chicago, and thence into the canal, and thence into the Illinois river, and they would flow down the Illinois river, there woudl be a majority, which would be fifty per cent., disappear in from five to seven days?

A. I think that the more there were, the quicker they would die out.

11816 Q. What reason have you to believe that?

A. On account of the exhaustion of the pabulum more quickly.

Q. Exhaustion of the food?

A. Either exhaustion of the food or the production of substances inimical to their life.

Q. But with the addition of the water from Lake Michigan, at the rate of 250,000 cubic feet per minute, that would have a tendency to spread them, furnish them fresh water, and as they are motile, to enable them to swim anway from the objectionable substances, would it not ?

A. But I am not of the opinion that it would be sufficient—

Q. Don't you think that is important to know whether it is sufficient or not?

A. Yes.

Q. Well, then, if it is important to know the effect of the added volume of water upon the typhoid bacilli, and you have not obtained the comparative relationship existing between the sewage and the volume of water added, how can you express an opinion as to when the typhoid will disappear?

A. My opinion is expressed on the information I have; not upon anything else.

Q. Then your opinion could not be relied upon because you have not been furnished proper information on all sub-
11817 jects bearing upon the controversy?

A. I should have to leave it to others to decide as to the value of my opinion.

Q. Well, would you not consider it valuable to know the relation existing between the sewage and the added volume of water, 250,000 cubic feet per minute?

A. It, like many other facts, would be valuable to know, but I cannot know everything.

Q. You think there is no way of determining that at all?

A. I think perhaps some time we shall be able to determine that.

Q. How would that determination be made?

A. I think a great deal of light could be thrown upon it by trying percentage relations of lake water and sewage,—different percentage composition relations, and make laboratory tests.

Q. Now, I understood you to say that you have no information or knowledge as to the longevity of the typhoid germ except that which you obtained from literature?

A. And from conversations with —

Q. Bacteriologists?

A. With bacteriologists and my observations in the laboratory, on the duration of the life of the bacilli in various kinds of media. 11818

Q. Now, I will ask you this question, if it is not a fact that bacteriologists disagree, or, rather, all agree that the exact time of longevity of the typhoid bacilli cannot be and has not been determined?

A. Under all conditions, yes.

Q. Under all conditions—and cannot be determined under all conditions, and do they not further agree that the life of the typhoid germ in a running stream ranges from ten to ninety days?

A. No, I don't think they all agree on that.

Q. I will ask you if Professor Jordan has not stated that upon examining the life of the typhoid in Lake Michigan water, he has found that it lived ninety days in that water?

A. I do not recall his statement.

Q. Did he not publish that statement?

A. May be, I do not recall it.

MR. TODD: I object; the publication is the best evidence of what Professor Jordan says.

MR. JEFFRIES: You put a witness on the stand that speaks in no other way except what he understands from publications.

MR. TODD: I submit the statement of counsel is not borne out by the testimony of the witness.

MR. JEFFRIES: I will ask the witness now at this 11819 point in the record, if he has had any experience in testing the longevity of the typhoid bacilli in water?

A. Yes, I have in water in the laboratory.

Q. But that was distilled water and not river water?

A. It was pure water, sterilized water.

Q. How long did they live there, Doctor?

A. I do not recall.

Q. More than three months?

A. It is so long since I have worked with the—

Q. What is your opinion now; what is your recollection; it was more than three months, wasn't it?

A. My opinion is that they died out before that time.

Q. Before three months?

A. Yes.

Q. All of them?

A. Yes.

Q. Before two months?

A. My memory about that is worth nothing.

Q. And that is your only practical experience?

A. On that particular point.

Q. Is that not the most important point in self-purification of streams?

A. The longevity of the typhoid bacillus?

11820 Q. Yes, the longevity of typhoid bacillus?

A. The longevity of its life under the especial conditions of each individual stream, I think is one of the most important points.

Q. And that is true with reference to the Illinois river, is it not?

A. It is true of all rivers.

Q. You said something yesterday, Doctor, that in your opinion 10,000 cases of typhoid fever in Chicago were less harmful than ten cases at Peoria; what do you mean by that?

MR. TODD: I will state that you did not give all that he said. He said that ten cases at Peoria would affect Pekin—

MR. JEFFRIES: Well, yes, all right.

A. I think it was Peoria and Pekin, or Averyville and Wesley. Two places close together, at any rate, very close together. I meant that I thought the menace would be greater to the health of the people drinking the water a short distance from the place where the dejecta of ten typhoid cases were being poured into the water than it would be from 10,000 cases 125 or 150 miles away.

Q. What percentage of removal of typhoid germs did you have in mind when you made this statement?

A. I had no percentage in mind.

11821 Q. It was an off-hand statement, then, was it?

A. It was a general statement.

Q. Based upon any scientific knowledge?

A. Based upon all my scientific knowledge.

Q. On no practical experience, though?

A. On all my practical experience.

Q. Would 15,000 cases of typhoid at Chicago be equal to ten cases at Peoria so far as Pekin is concerned?

A. I should think that 15,000 cases would be less dangerous. The more typhoid bacilli beyond a certain number the quicker in my opinion they would die out.

Q. How do you know?

A. I don't know; it is my opinion.

Q. Do you know of any standard authority by which that opinion can be verified?

A. I should have to leave that to you to compare with them.

Q. Well, you have nothing to say on that?

A. I have nothing to say on that.

Q. Well, do you know of anyone else that has the same opinion?

A. I think that the best informed minds in the country, dealing with this problem, would have the same opinion.

11822 Q. Now, who are they?

A. Well, I am of the opinion that Professor Welch of Johns-Hopkins would have the same opinion.

Q. Did Professor Welch ever have any experience in water supplies of cities?

A. I do not know that he has worked out any water supply.

Q. Don't you know that he has not?

A. I don't think he has; but I don't think that would make any difference with regard to the formation of the opinion in his case.

Q. You think, then, that anybody could make use of the same expression and it would be of as much value as though made by an epidemiologist?

A. Dr. Welch is an epidemiologist. I don't think that anyone having less brain capacity could give as good an opinion as Dr. Welch.

Q. We are speaking now about this opinion that you gave with reference to the 10,000 cases at Chicago and the ten cases at Peoria, and their effect upon the water at Pekin?

A. I am inclined to think that Dr. Welch would give that opinion, but I could not speak for him.

Q. Well, has he ever given an opinion of that character?

11823 A. Not in any special typhoid cases, though, it is in accord with his general views.

Q. Has he written a book on the subject?

A. No.

Q. Has he ever given a professional opinion upon water supply matters?

A. In Court do you mean?

Q. In Court or anywhere else?

A. Oh, he has given private opinions on water supplies. I don't think he has ever testified in Court.

Q. He has given private opinions, just as you have, by examining the water in the laboratory?

A. On the basis of his general epidemiological knowledge.

Q. He is a pathologist, is he?

A. He is a pathologist and bacteriologist, and in the highest sense of the word an epidemiologist—erste klasse.

Q. Doctor, how many typhoid epidemics have you personally studied?

A. I have been interested in typhoid epidemics in three cities—four cities really, but in the sense of studying the water supply relations, as I told you yesterday, I have not studied any personally.

11824 Q. Then you have no personal experience along that line?

A. No personal experience, no.

Q. Doctor, is not sedimentation more extensive in the lake, and in lake water, than it is in a running stream? In other words, is it not much greater; doesn't sedimentation take place much faster in the lake?

A. You mean at all times?

Q. Yes, as a general proposition, now.

A. I don't think it would be true at times when the lake is badly disturbed.

Q. Well, Doctor, the same character of motion that permits sedimentation in a lake, will permit it in a river, won't it, and if the movement of water in the lake will permit sedimentation in that lake, will not the movement of water down stream in a river permit sedimentation in the river?

A. There are very different movements in a lake and in a river.

Q. How so?

A. You might have in the lake some of the same movements that you have in the river, but you have in the lake movements at times that are quite different—for instance, disturbances from the wind and waves, that you do not get in the river to such an extent.

11825 Q. Well, cut out the wind action in both instances.

A. I have made no especial study of current in lakes and rivers and am not prepared—

Q. Therefore, you don't know what effect sedimentation would have, whether it would have any or not?

A. I think it would have a very marked effect in both places.

Q. Do you know how long typhoid germs will live in the sediment of Lake Michigan?

A. No.

Q. How?

A. I do not. I don't think very long.

Q. Well, how long?

A. I should doubt if they lived—it would all depend on what part of the lake they were in, and how much sewage contamination there was where they entered the lake.

Q. Well, in the sediment of the lake?

A. That is the point in the sediment where there is much sewage dumping, at the same time they would be destroyed very rapidly, whereas in pure water, with little sewage, it would, I think, live longer.

Q. What would destroy them in the sediment?

A. The chemical processes going on there.

Q. What chemical processes?

A. They are unknown to us.

11826 Q. Well, now, do you know that they are destroyed?

A. Well, I don't know about the sediments in Lake Michigan, but I am judging on the basis of my general experience as an epidemiologist.

Q. Well, generally are they destroyed?

A. Yes, I think so.

Q. Well, give us some instances?

A. I cannot give you any instances.

Q. Did anybody ever pretend to give an instance?

A. I don't know how much experimental work has been done.

Q. Don't you know that there has been a great deal of experimental work done on that subject and yet they have been unable to ascertain that fact?

A. The conditions of the experiment of course are very difficult, but we have to judge by the biological results.

Q. Don't you know that typhoid germs will live for more than a year in soil and in sediments, and that it is on record?

A. It has been known that they live as long as thirty days; at least it has been asserted that they have lived as long as thirty days, and endorsed.

Q. Do you know that it is on record that they live in earth as long as a year?

A. I know of no such record. It may be there.

11827 Q. If it should appear in this German book that you have stated—what is that book?

A. Baumgarten's Jahresbericht.

Q. Would that have any effect upon your opinion?

A. Not unless the man who made the observation was a reliable man. Baumgarten's to some extent is just a review of all the opinions expressed along these lines, and I would base my opinion entirely upon the ability of the investigator who did the work.

Q. Have you ever taken the trouble to look up the literature?

A. Not on that particular point.

Q. Can you tell us some of the men whose experiments are found in that book, that are reliable?

A. In general on bacteriology?

Q. Yes?

A. Yes, I can tell you.

Q. You have been looking them up since yesterday, have you?

A. Oh, I know quite a few of the reliable bacteriologists,—Koch and Pasteur would be two very reliable men.

Q. How about Frankland, of England?

A. I would regard his opinion as a very valuable opinion.

Q. I will ask you, Doctor, if it isn't a fact that typhoid fever germs have been found in the sediment of Lake
11828 Geneva, a long distance from the source of pollution?

A. I didn't know that that had been demonstrated.

Q. Would it modify your opinion in any way if that should appear and be shown to you, as to the effect of sedimentation upon the water in the Illinois river?

A. No, the conditions in Lake Geneva are quite different from the conditions in the Illinois river.

Q. What are the differences in the conditions?

A. Lake Geneva is a mountain lake, situated under the Dendu midi, and at the outlet of the Roan valley; the Roan river empties into it. It is surrounded by a number of clean cities and all over are high hills; it is a typical Alpine lake.

Q. Its water is polluted, if it contains typhoid, is it not?

A. If the water contains typhoid fever bacilli, it is polluted, certainly.

Q. Doctor, in talking of the water at Lawrence, which was held in the reservoirs for fourteen days before use, containing typhoid fever germs, that water was polluted, was it not, as well as the water in the Illinois river that we are talking about, and sewage polluted at that?

A. Relatively slightly polluted, so far as general sewage is concerned.

Q. Was it not very greatly polluted so far as the ty-
11829 phoid is concerned?

A. Yes, it must have been.

Q. Being infected with typhoid fever germs, Doctor, the source of that infection was sewage, was it not?

A. I should think it was.

Q. Then why is there any difference?

A. Because the water there was a drinking supply water—a much purer water, as I understand it.

Q. And still it produced the worst typhoid epidemic that science records?

A. Well, I don't know that that is true, but it produced a very bad epidemic, and I think that that is one of the most significant things about this whole question, that even the water that looks to be of the purest of water, might be the most dangerous.

Q. And that is one way why you cannot definitely determine that the Illinois river at Grafton does not contain these germs?

A. I certainly would not recommend its use without submitting it to all possible tests.

Q. And what happened at Lawrence, Massachusetts, with fourteen days' sedimentation, is liable to happen to any city using water that has been sewage polluted, and being 11830 within fourteen days' travel from the source of pollution?

A. No, I don't think that would be true. I think any water existing under the same conditions as that at Lawrence, is liable to give exactly the same results.

Q. Do you know what the conditions were, existing there?

A. Not exactly, no.

Q. Well, how do you know that the conditions there are not similar to the conditions here?

A. Because you have told me so, for one thing, and I have read of the epidemic myself, and know about the reservoir.

Q. How do you know, Doctor, that the sewage pollution in the water in the reservoirs at Lawrence, was no less than the sewage pollution of the water in the Illinois river at Averyville, or at Grafton?

A. I have no absolute knowledge on the fact; it is simply my opinion that it was not.

Q. Then, Doctor, I will ask you again if it is not your opinion that the more sewage that you deposit in a running stream, the less danger there is from pathogenic germs?

A. The more sewage?

Q. The more infected sewage that is deposited into a running stream the less danger there is from typhoid fever.

A. Where?

11831 GENERAL CROW: Anywhere on the running stream?

MR. JEFFRIES: Anywhere below the point the sewage is discharged into the river?

A. But of course that is not true. That would be in utter opposition to all our knowledge. It would be true for distant points in the stream, but it would be very untrue for points nearby.

Q. Now, then, why would it be true for distant points?

A. Because in my opinion the typhoid bacilli would be killed off earlier, the greater the amount of sewage turned into the river at the initial point.

Q. Then you mean by that, Doctor, that they would be killed or die out quicker and near the source of pollution, where it was largely polluted with sewage, than they would where there was less sewage pollution?

A. Yes, but the exact percentage relations again, I don't know about of course.

Q. Well, Doctor, assume that the sewage of Chicago, containing two millions of people, was discharged into a running stream that received no other water, how far would it run before it would be free from typhoid and other pathogenic germs?

A. Received no other water except what water?

11832 Q. Except the sewage?

A. Pure sewage.

Q. Pure sewage flowing down the stream, a stream of sewage, an open sewer?

A. Wouldn't that dry up quickly?

Q. Well, that is for you to say.

A. I have never seen the experiment tried. I don't know what would happen.

Q. You don't know how long, or how far it would travel?

A. No.

Q. Nor how long the typhoid germs would live, nor how long any other bacteria would live?

A. No.

Q. Have not there been experiments made with reference to the longevity of pathogenic germs in the sewage?

A. Yes, experiments have been made, but in my opinion the results are so conflicting and the experiments are so difficult that the data are very unsatisfactory.

Q. Now will you name some of the men that have given conflicting opinions?

A. I cannot. I would again look them up in the same journals.

Q. Now, doctor, assuming that there was an equal amount
of water added to the sewage discharges of a city of
11833 2,000,000 of people, such as Chicago, how long would that
mixture be required to run in a stream before the pathogenic bacteria are destroyed, such as typhoid fever germs?

A. I have already said that it was very desirable that percentage relations be experimented with and I know of no definite experiments of that sort. My opinion would be that the typhoid bacilli in such a mixture would die out within five days.

Q. Now supposing you double the quantity of water again?

A. I am of the opinion that that would make no difference.

Q. Supposing that you would increase that water until you had 250,000 cubic feet per minute?

A. I am not sure that that would make any great difference.

Q. Suppose you would increase it until you had a million cubic feet per minute?

A. I think if you increased it until it approached a pure water it would increase the longevity of the typhoid bacillus.

Q. Can it be increased until it would reach a stage of pure water? Isn't that an absurdity?

A. I think as it approached the stage of the purer water—

Q. Well, could you by the addition of water into that sewage of any volume whatever, render it so that it would be recognized as a pure water, by mere addition of water?

11834 A. Well, what I meant by pure water there would be a
water that chemically would be within the domain of pure

water; of course it would not be pure if it had typhoid bacilli in it.

Q. It might not show in the chemical analysis, doctor?

A. That is true.

Q. It might not appear in the bacteriological analysis?

A. Oh, I think if the saweage were diluted so that chemically the water appeared pure, that at that stage at any rate, and probably before, the longevity of the typhoid bacillus would be increased.

Q. But you do not know to just what extent it would be increased?

A. No, I don't think we have data sufficient to tell that.

Q. Then I want to ask you, doctor, if acording to your theory it would not have been better for Chicago to have turned their sewage into the Chicago river, and the Chicago river into the river Desplaines and thence into the Illinois river, instead of constructing a canal and discharging the sewage mixed with 250,000 cubic feet of water per minute, in the river?

MR. TODD: I object to the question unless it applies to the State of Missouri.

MR. JEFFRIES: That is, wouldn't it have been better
11835 for the disappearance and disposal and death and destruction of pathogenic bacteria?

MR. TODD: I object to the question, unless the question is limited to the effect of the discharge of the sewage of Chicago into the river in either of these waters, upon the inhabitants of Missouri, as that is the only issue raised in the pleadings in this case, and what effect it may have upon the inhabitants of Illinois immediately below Chicago, on the Desplaines and Illinois rivers, is not material or competent in this inquiry, and for the further reason that as to the methods employed by Chicago in the disposal of its sewage or the purification of its water is a matter that is not competent to be inquired into in this controversy, as the question involved in this case is the discharge of the sewage through the drainage canal a danger and a menace to the inhabitants of the State of Missouri?

A. My answer to the question would be that I do not know enough about the engineering part of the problem to pass judgment.

MR. JEFFRIES: Has the engineering anything to do with the destruction of the typhoid bacilli?

A. Yes, the rate of flow, and the physical conditions of the river would have a great deal to do with it.

11836 Q. And those you have not studied?

A. I have a great deal of information which I have given you about it.

Q. There is not a particle of difference, doctor, in the supposition that is assumed in this question, and in the condition from which you have previously testified, the canal is; they are just the same?

(Question repeated). (No answer).

Q. Would it not have been better for the destruction of the pathogenic bacteria from the city of Chicago to have turned the Chicago river into the canal?

A. Into the Illinois and Michigan canal?

Q. No, into the canal as it now is, into the drainage canal, without turning the lake water in?

A. I am not sure that it would have made any difference as far as the destruction of bacilli was concerned.

Q. Well, do you know whether it would or would not?

A. I don't know.

Q. What is your opinion on it?

A. My opinion is that it probably would not make much difference, but I should like to see experiments conducted on percentage composition relations.

11837 Q. Then it was unnecessary to turn the water in, was it?

A. My opinion on that particular point might not meet with general approbation; I don't know.

Q. Does septic action obtain in the canal?

A. What do you mean by septic action, if I may ask?

Q. Well, do you know anything about septic action?

A. Do you mean septic processes in a septic tank?

Q. Yes.

A. Yes I should think so.

Q. Does it in the present canal?

A. I have not examined into that at all.

Q. You have seen it, have you not?

A. Yes, I have seen it.

Q. You know that there is being constantly added every minute, 250,000 cubic feet of water passing through the canal and the sewage of Chicago going into it?

A. Yes.

Q. You know that it is about 27 miles long?

A. Yes.

Q. And you know about its depth and its width?

A. Yes.

Q. Now I will ask you if in your opinion as an epidemiologist it has any septic operation?

11838 A. Corresponding to what goes on in a septic tank?

Q. Yes?

A. Yes, I think there is undoubtedly many of the same processes going on.

Q. Is it not true that dissolved oxygen is always present in the Chicago drainage canal?

A. I don't know; I should think it was true.

Q. Did Professor Long or Professor Jordan tell you that they, in their examinations, had shown that dissolved oxygen was present at all times and at all seasons of the year in the drainage canal?

A. No.

Q. You made no inquiry on that point?

A. No.

Q. Either before or after you knew that you were to be a witness in this case?

A. No.

Q. Isn't it a fact that septic operation cannot take place in the presence of dissolved oxygen?

A. It all depends on your definition of the term septic operation.

Q. Well as currently applied to a septic tank and septic operation in sewage disposal?

A. I should think that some of the same processes

11839 would certainly go on, even in the presence of oxygen.

Q. On what do you base that opinion?

A. On my general knowledge of chemistry.

Q. You are a chemist?

A. I utilize chemistry in my work; I am not a specialist in chemistry.

Q. Can oxidizing action and reducing action go on at the same time?

A. In different parts of the same organism, yes.

Q. In simply the organic matter in the canal?

A. Some organic matter might be oxidized while other organic matter was being reduced.

Q. That is not true as a general proposition, is it?

A. Yes, it is.

Q. On what do you base that opinion?

A. On the general law of chemical equilibrium.

Q. Isn't it a fact that the present dilution was provided for with reference to the Chicago sewage, in order to avoid the very thing that you have been testifying to?

A. I don't know.

Q. You don't know?

A. No.

Q. If it would appear that it was so, would it modify 11840 your views in any way?

A. No.

Q. Then you would not give septic action any credit or weight in your opinoin,—any consideration in your opinion?

A. What is that?

Q. You would not give septic action—you do not consider it of any consequence in giving your opinion?

A. Why of course I consider it of great consequence.

Q. Isn't it a fact, doctor, that this canal was constructed and this added volume of water introduced for the purpose of preventing septic operation and putrefactive changes?

A. I have no definite information.

Q. And isn't it a fact that it does prevent?

A. I had supposed that the canal was produced to protect the city's water supply.

Q. And no other purpose?

A. And to remove a nuisance from the immediate neighborhood of the city.

Q. And what created that nuisance, putrefaction, was it not, the destruction of the organic matter?

A. Near the city, very close to the city.

Q. And the water was introduced for the purpose of carrying it on away from the city?

11841 A. As I understand it.

Q. And has it carried it away—has it carried the organic matter in its original condition further away?

A. No, not in its original condition, because it was changing all the time, as it flowed.

Q. What changes are there in it, up to Lockport?

A. It is still much contaminated at Lockport, as I understand it.

Q. Is there any reduction in organic matter between Chicago and Lockport?

A. I have not the details by me.

Q. You don't know, do you?

A. No, I don't know.

Q. Well then, you don't know whether septic operation takes place or not?

A. From my general knowledge of what occurs in septic operations I should say that a great deal had taken place before reaching Lockport.

Q. Didn't you know, doctor, that as applied to conditions for treating sewage by the septic tank process and by septic operation, that there is no such condition exists in the Chicago drainage canal?

A. That depends upon your definition, as I said before,
11842 of septic operation. Certainly great changes have taken place.

Q. As applied to sewage disposal, I will ask you?

A. My answer would be that great changes certainly do take place.

Q. They are not septic, though?

A. I would call them septic, but perhaps others would not.

Q. Did you ever see a septic tank?

A. Yes.

Q. For sewage disposal?

A. Yes.

Q. Where?

A. I have seen experimental ones; not in actual operation, for cities.

Q. Doctor, do you know anything about the population upon the drainage area of the Illinois river?

A. I think in the statistics that were put in there, there was data as to the population of the principal towns, but the total number I don't know.

Q. Do you know anything about the population upon the upper Mississippi?

A. The same remark applies to the Mississippi and Missouri rivers.

Q. Did you ever study those towns and cities with reference to their sewage disposal? 11843

A. No.

Q. As to whether the towns were sewered or not?

A. I know that some of them were sewered.

Q. Do you know whether Louisiana is sewered?

A. No.

Q. Quincy?

A. No.

Q. Keokuk?

A. No.

Q. Davenport?

A. No.

Q. Rock Island?

A. No.

Q. Any of those large cities?

A. No.

Q. That would have a very large effect upon the water in the Mississippi river?

A. Nearby, near the source of pollution, yes.

Q. Do you know of any town that pollutes the water supply of St. Louis?

A. I know that some town pollutes the water supply of St. Louis.

11844 Q. Well, do you know any particular town?

A. No, I know the water supply is polluted by the amount of typhoid that is occurring.

Q. But you don't know the source of that pollution?

A. No, I do not.

Q. Is it Peoria?

A. I shouldn't think so. I should look for it tolerably close by.

Q. What distance?

A. Well, I should look for it within twenty-five or thirty miles.

Q. And you would take no cognizance of any city above twenty-five or thirty miles?

A. Oh, I don't say that, but I should look first very assiduously within thirty miles.

Q. How far up the Mississippi river or any of its tributaries would you go to look for the source of pollution, if you found the water at St. Louis to be polluted.

A. I don't think that I would consider anything beyond 75 miles as important, counting ordinary rate of flow.

Q. What in your opinion is the effect of the Cincinnati sewage upon the Louisville water supply?

A. I don't know about it.

11845 Q. Have you ever read the literature upon that subject?

A. I have been looking at the very high death rate from typhoid fever in Cincinnati. I know that it is a very high death rate.

Q. Have you examined the death rate in Louisville?

A. In Louisville, Kentucky, I have the figures here before me. I have been looking over these figures today. We had 121 deaths with a population of 217,000 in the year 1901.

Q. Isn't it true that that water at Louisville passes through a reservoir holding five to seven days' supply?

A. I don't know.

Q. Well, you know that that is sewage polluted water, do you not?

A. The Louisville water supply?

Q. Yes?

A. I should think it would be from the number of typhoid cases. My attention has not been called to it.

Q. Standing from three days to thirty, from the source of pollution, and yet knowing that the water supply at Louisville was obtained from that source, what would you say as to its sanitary condition—three days for the water to flow from the source of pollution to Louisville, in the river itself, and five days additional in the reservoir, and yet that water 11846 when taken into the reservoir produces typhoid fever and is a polluted water.

A. Is there no chance of contamination on the way?

Q. No sewered towns within ninety miles.

A. Is the water guarded and protected all the way from contammination? Unless it is guarded and protected entirely from contamination, an opinion as to the more distant city would not be very valuable.

Q. Would you take the judgment of reputable men who had examined into it, and who had stated as epidemiologists that that was the source of pollution, as true?

A. It would all depend upon who those men were.

GENERAL CROW: Would it depend upon your personal acquaintance with them?

A. My own opinion would depend upon information I could get as to their reliability, information in which I had confidence.

MR. JEFFRIES: Your opinion, however, is that if a man says that typhoid germs will travel longer than five days and further than 150 miles, that it is not very valuable?

A. No, I would not put it quite that way.

Q. I will ask you, doctor, if the time factor is not more important than distance?

A. I think they are both very important.

Q. Well isn't the time factor more important than distance? 11847

A. Other things being equal, I should say yes.

Q. Well, what do you mean by other things being equal? Don't you know that the time factor is a most important question to be considered by an epidemiologist in determining the source of pollution of water?

A. No, I am not sure that it is. I think that other influences, for instance, the amount of saprophytic bacteria, the amount of sedimentation, are just as important factors to consider.

Q. Then if you saw opportunities for saprophytic operation, and you saw opportunities for sedimentation, whether they would be fancied or not, that would be a justification in stating that the source of pollution was not above a certain point; is that true?

A. If the opportunities for saprophytic action and sedimentation were fanciful, I don't think that one could—

Q. Cut out the "fancy;" I didn't mean to put that in there? (Last question repeated.)

A. The question is not clear to me; I don't quite understand it.

Q. In the examination for the purpose of determining the source of pollution, you were told that the source of pollution was from a town or city situated 150 or 200 miles above
11848 the point affected, you would find that before you reached that point supposed to have been the source of pollution, that there were opportunities for saprophytic action, and also opportunities for sedimentation, as soon as you found that there was an opportunity for the saprophytes to get in their work and an opportunity for sedimentation, you would say at once, there is no need of going any further. That is the end of this controversy; that could not be the source of this infection?

A. Provided the time for those influences were great enough.

Q. Now then, the time for those influences to act, depends altogether upon the longevity of the disease producing germs, does it not?

A. Under the particular conditions.

Q. Under what particular conditions, doctor?

A. Under the particular conditions of the case. They vary in every instance.

Q. Doctor, do you know about the typhoid conditions at Covington, Kentucky?

A. No.

Q. Do you know that the water is held in settling basins for thirty days and yet it is typhoid infected after it is held in that basin thirty days and distributed to the people?

11849 A. I do not know the conditions at Covington.

Q. Now then, doctor, if it could be held in a settling basin for thirty days, with the opportunities for sedimentation there, are not there more facilities for sedimentation in that basin than there would be in the Illinois river coming from Chicago to St. Louis in less than thirty days?

A. I should think there would be more opportunities for sedimentation.

Q. Then on the question of sedimentation, if it remained in a settling basin thirty days at Covington, and still carried the typhoid germs into the water supply, to the people and produced typhoid, would not and are there not strong reasons to believe that they would be carried free from sedimentation, from Chicago to St. Louis?

MR. TODD: I object to the question for the reason that there is no evidence in the record that the water supply of Covington remains thirty days in a settling basin, and is a cause of typhoid fever in Covington.

MR. JEFFRIES: We can prove it by some of this literature that counsel admits that this witness has read, when the witness bases his experience and his qualifications altogether on literature that has been read by him, as entirely compe-
11850 tent.

MR. TODD: I submit counsel's statement as to his qualifications is not borne out by the evidence of the witness.

MR. JEFFRIES: And I suggest further that the testimony for the complainant shows that this particular instance was shown in evidence with reference to conditions existing at Covington, Kentucky.

MR. TODD: I suggest that it is not.

Q. (Last question read).

A. My answer to that is that I don't know enough of the conditions at Covington, Kentucky, as related to me here, to pass any opinion on that.

Q. MR. JEFFRIES: Well, doctor, if they would remain in a settling basin for thirty days and not be sedimented, would they not pass down a running stream the whole distance, for thirty days, or in less than thirty days, and not be sedimented?

MR. TODD: I object to the question for the reason that the assumption of thirty days is not borne out by anything in evidence, and on the contrary it has been proven here by the complainant that in the settling basins of St. Louis, that the water in there for three days, ninety per cent. of the bacteria disappears in those three days from the water supply of St. Louis.

11851 MR. JEFFRIES: That was not shown under all conditions.

THE WITNESS: My answer to that is that I have no opinion to offer on that subject.

Q. Will you state that they would not come from Chicago to St. Louis and not be subject to sedimentation or not be sedimented?

A. In my opinion they would not pass from Chicago to St. Louis alive?

Q. Because of sedimentation?

A. Partly because of sedimentation.

Q. Speaking now of sedimentation alone, doctor, eliminating everything else?

MR. TODD: I submit that the question is improper, to confine the witness to one fact when there are other facts, as heretofore testified by the witness, that have been repeatedly stated as the reasons.

MR. JEFFRIES. I submit that the witness has yet failed to give all of the causes of disappearance, and therefore I have the right to confine him to each one, and limit it to each source of disappearance, in order that I may determine.

A. My answer then to that would be that I don't know whether sedimentation alone would account for the disappearance of the typhoid bacilli or not.

11852 Q. What is your opinion?

A. I am not prepared to offer an opinion on that.

Q. Have you an opinion?

A. No fixed opinion.

MR. TODD: That is as to sedimentation alone.

A. Sedimentation alone. That is what I said.

MR. JEFFRIES: Doctor, what is it that contaminates the water supply, or pollutes it?

A. A great many different things, the most important being bacteria capable of producing disease.

Q. And where do those bacteria come from?

A. Usually from the bodies of infected individuals.

Q. And how do they get into the water supply?

A. Usually through sewage.

Q. Then sewage pollution is the principal cause of infected water supplies?

A. Yes, I should say so.

Q. You say you have examined none of the cities on the upper Mississippi with the view of determining the extent of their sewage disposal?

A. Yes.

Q. You have not?

A. I say that I have not.

11853 Q. You don't know what effect they would have upon the waters of the Mississippi river?

A. I would have an opinion corresponding to the distance they are away, and the time that that water takes to come down.

Q. Now, then, it is a question of distance and time, is it?

A. No, together with the physical conditions of the river, physical and biological conditions of the river.

Q. What do you have reference to,--the biological conditions of the river?

A. The life phenomena of the river.

Q. What do you mean by the life phenomena of the river?

A. Everything living in the river, animal and vegetable.

Q. You are not able then to express an opinion as to where the source of pollution in the Mississippi river at St. Louis is?

A. No, I have not examined into it thoroughly enough to have any opinion.

Q. What towns are there that you know of within what you would consider the limit of pollution of the water at St. Louis?

A. I have made no special examination of that point. I would look first for towns within twenty-five miles of the city, 25 to 30 miles of the city, and I should expect to find it somewhere there. 11854

Q. How far would you have to go, doctor, before you would eliminate the towns and cities on the river, and the sewage disposal thereof, from your consideration?

A. I should think it very improbable that any place within seventy-five miles, was responsible,—any place further away than 75 miles was responsible.

Q. Then it is your opinion, is it, that if all the sources of pollution for a distance of 75 miles from the city of St. Louis, by water, were removed, there would be no danger from typhoid fever or other water-borne diseases?

A. From the water supply?

Q. Yes, is that your opinion?

A. Yes, that is my opinion.

Q. Now, would that water be equal to the water in the river in its primal condition, after it had traveled seventy-five miles, without having received any additional sewage?

A. Would it be exactly in its primal condition?

Q. Yes?

A. I don't know.

Q. But would it be equal to it from a sanitary standpoint?

A. There is no evidence that it could produce typhoid, in my opinion, which is the point which we are interested in.

11855 Q. Then, doctor, in these cases in the literature, where it has been stated that the sources of typhoid epidemics have been traced a distance from 100 to 175 miles up a river, you don't credit them, do you?

A. I do not—

MR. TODD: Wait. I want to put an objection in there as there is no evidence and none has been produced that there is any case in the literature of typhoid fever coming a distance of 175 miles.

MR. JEFFRIES: Well, I will show you some.

A. My answer will be the same. I do not credit it.

Q. You don't believe that it can come that far?

A. All the evidence is against it, in my opinion.

Q. Can you imagine any circumstances under which it could come except that it be put in as you stated a while ago, in distilled water?

A. I might imagine other methods.

Q. Can you determine, doctor, the exact distance that the water polluted with sewage will travel before it becomes relieved of that sewage?

A. The exact distance, no, because it varies in every river—

Q. Now, what are the variations?

MR. TODD: Let him finish.

11856 A. Because it varies in different rivers, and in the same river at different times.

Q. What are the variations?

A. The variations correspond to variations in the various influences, physical, chemical and biological and atmospheric.

Q. But it cannot be determined just exactly what those variations are, or the extent of the pollution or the extent of the purification?

A. They are not constant.

Q. They are not constant and therefore it cannot be determined the exact limit, is that true, and the differences in that limit depend upon the longevity of the disease producing germs?

A. This limit of purification depends upon the presence or absence of pathogenic germs.

Q. Upon the longevity of?

A. Under particular circumstances.

Q. Does it not depend upon the longevity of pothogenic germs under all circumstances?

A. It depends in each case upon the longevity of the germs in that particular instance.

Q. And the longevity in no particular instance can be applied to all conditions and all periods as applied to that one river?

A. It can be applied generally, but not exactly.

11857 Q. Can it be applied so that it can be relied upon and so that you might pass judgment upon a water as being safe for sanitary purposes?

A. It is sufficient to permit you to form an opinion.

Q. An opinion that can be relied upon?

A. An opinion that is the best one that can be formed under the circumstances.

Q. But is it an opinion which can be relied upon and is it a condition that you could recommend?

A. I would not recommend the use of any water that wasn't filtered or boiled.

Q. Does that apply to waters in their primal condition?

A. I think it would be sufficient in their primal condition. There might be some pathogenic amoebae in there or something of that kind.

Q. Do you consider freezing temperatures in fixing the limit?

A. In fixing a limit to the life of pathogenic bacteria?

Q. Yes, and in ascertaining the point in the river at which purification has taken place and pathogenic germs have disappeared?

A. Pathogenic germs can live in ice, some of them, for a very long time.

11858 Q. If ice should freeze in the Illinois river above Averyville and there would be typhoid fever in the water that is frozen and that ice should float down to the Mississippi and melt on its way from Grafton to the Chain of Rocks, typhoid fever germs would be distributed in the water of the Mississippi river, would they not?

A. Assuming that the typhoid bacilli were alive when the piece of ice melted, there would be typhoid bacilli in the river water.

Q. Well, if it came down within thirty days, they would be likely to be alive, would they not?

A. They might be. We know that typhoid bacilli can live some time in ice. I don't know the exact time it has been proven they can live.

Q. Would a block of ice coming from Lockport be more dangerous than one from Averyville?

A. I think it would, provided the typhoid bacilli lived in it.

Q. Doctor, do you know of any city in this country with two millions of people, similarly situated as Chicago, discharging its sewage into the river like that?

A. I don't think there is any city situated in the same way as Chicago.

MR. TODD: Of that population?

11859 A. Of course, of that population.

MR. JEFFRIES: With two millions of people?

A. Yes.

Q. Well, now, doesn't the number of population and the sewage discharges of a city of that population have a great deal to do with the extent of the pollution in the river?

A. With the amount of sewage poured into the river?

Q. Yes?

A. Yes.

Q. And as the amount of sewage is increased the pollution continues further down the stream?

A. As I said this morning, it is conceivable that typhoid bacilli might be killed off more quickly with a large amount of sewage than with a smaller amount of sewage.

Q But I understood you to say that you refused to express any opinion on that subject.

A. I have not expressed an opinion. I have said it is conceivable.

Q. Of what value is it to you in passing upon the sanitary condition of water?

A. Of what value is that conception?

Q. Yes.

A. Well, it is one of the things one thinks about, of 11860 course, in forming an opinion; one tries to draw all ideas together.

Q. Doctor, have you studied the characteristics of the saprophytes in water?

A. In river water?

Q. Yes?

A. No.

Q. Isn't it a fact that you have no actual experience with saprophytic life in water?

A. Oh, I have had laboratory experience with saprophytes.

Q. But not with water taken from the rivers and lakes in connection with the longevity of the typhoid fever germ?

A. No.

Q. And from this river that we are talking about—the Illinois river?

A. No actual personal experiments have I made.

Q. And all that you know is just simply what you have read?

MR. TODD: I submit that that question has been asked three times and been answered twice.

MR. JEFFRIES: It never has been answered.

MR. TODD: I submit that it has, and the record will show.

A. I pointed out this forenoon the sources of my knowledge and information upon which my opinions are based.

Q. Now, all that you know of the saprophytic action of 11861 the water in the Illinois river, and in the Chicago drainage canal is not obtained from any personal examination of that water, but has been obtained from your conversations with Professor Jordan and Professor Long?

A. And my general knowledge of subjects relating thereto.

Q. To that river?

A. To the whole problem of rivers.

Q. You stated, Doctor, that those saprophytic conditions would be different in the various waters, did you not?

A. Yes, I pointed out that only general conclusions could be drawn, and that the special circumstances of each river should be studied in themselves.

Q. If each river should be studied for itself, and if you cannot tell the effect of the added volume of water in saprophytic life in a particular stream without studying those conditions, and those conditions are necessary, and saprophytic action is necessary to determine the sanitary condition below the point of sewage discharge, why is it that you have undertaken to express an opinion as to the sanitary condition of the water in the Illinois river at points below the city of Chicago?

A. I have already given my reasons for expressing my opinion.

Q. And you don't care to express any other opinion?

11862 A. No.

Q. Or to give any other reason?

A. No.

Q. But you have not in that opinion taken into consideration the saprophytic action in the Chicago drainage canal, have you?

A. No personal experiments.

Q. And it is necessary to have—

A. I do not consider—

Q. It is necessary to have the conduct of the saprophytes in that particular stream in order to express an opinion that would be reliable, is it not?

A. It is desirable to have all the information possible, but not necesary to have it to give the expression of opinion which I have given.

Q. Is it not necessary, Doctor, to have it?

A. I have answered that, haven't I?

Q. Doctor, do you—how do you reconcile your statement that you can determine or can express an opinion as to the effect of the added volume of 250,000 cubic feet of water per minute, to the sewage of Chicago, and discharged into the Illinois river, when at the same time you express an opinion as to the sanitary condition of that water, and at the same time state that the saprophytic conduct of the water is different in different rivers and is not the same in all waters? 11863

A. I base my opinion upon my knowledge as an epidemiologist, the foundations of which I have already given you.

MR. TODD: Read that question.

(Question read.)

THE WITNESS: My answer to that is, because there is no discrepancy between the two statements.

MR. JEFFRIES: One is not depending on the other; one has no connection with the other?

A. I say there is no discrepancy between the two statements.

Q. Then, Doctor, why can't you tell the effect and express an opinion as to the effect of the added volume of water upon the life of the typhoid bacilli in the Chicago drainage canal and the Illinois river?

A. Because I think actual experiments with percentage composition relations ought to be undertaken in order to get real knowledge on that particular point.

Q. Well, you admit that it has an effect?

A. I have admitted that it might have some effect.

Q. Then might it not have considerable effect at Averyville?

A. I don't think so; it is my opinion that it would not at Averyville.

11864 Q. And also your opinion that it would have no effect at Chicago in the drainage canal?

A. I have not said that; I said that I didn't know about that.

Q. Then it might and it might not?

A. Yes.

Q. Have you ever testified as an epidemiologist in a suit before?

A. Never.

Q. Have you ever been called upon to give an opinion as to the sanitary condition of a water supply as an epidemiologist?

A. I was called upon to pass upon private water supplies in Baltimore.

Q. That is the one you mentioned this forenoon?

A. Yes.

Q. And you stated, I believe, this afternoon, that you never had been connected with the construction of a water system in any way?

A. Yes.

Q. And your labor has been confined to the laboratory and to the hospital and to the literature with the exception of the few instances that you mentioned, when you went to California and Manilla and the Philippine Islands?

A. And India.

11865 Q. In all those cases you had nothing to do with tracing the origin of the disease but studying its character and its nature and its biology, in the hospital and among the persons who were affected by it?

A. We were tracing the origin of diseases.

Q. But not with relation to the water supply?

A. No, not in relation to the water supply.

Q. Doctor, have you examined the health statistics of the city of St. Louis?

A. I have examined certain parts of them.

Q. You examined them from the health reports?

A. I did.

Q. You made no other examination than that contained in the reports of the health department?

A. I have run across references to the health relations in literature.

Q. But with reference to the city of St. Louis now?

A. My statistics are drawn from the health reports.

Q. You have not gone to the health department and made any examination?

A. I have not.

Q. Have you examined any of the physicians or talked with any of the physicians of the city of St. Louis that had reported typhoid cases or malarial cases?

11866 A. I have not.

Q. With reference to the character of those diseases?

A. I have not.

Q. I understood you to say symptomology was the best way of determining the nature of the disease, particularly with reference to typhoid fever?

A. The detailed symptomology, in the broad sense of the word, including the physical signs and symptoms, and bacteriological tests.

Q. What do you say as to the accuracy of the Widal test?

A. I think it is one of the most reliable of the single tests, but as I pointed out, we depend upon the total symptom complex for our diagnosis rather than upon any one.

Q. You don't know, do you, the qualifications of the physicians of the city of St. Louis and the rules of the State Board of Health, do you?

A. You mean, have I read those rules?

Q. Yes?

A. I have not read the rules, no.

Q. You don't know of the circumstances which bring about the reporting of the cases of deaths from diseases, do you, in the city of St. Louis?

A. I made no special study of that point with regard to the city of St. Louis. 11867

Q. And you are of the opinion, are you, that observation of the symptoms in cases of typhoid fever, especially in cases which die, is the best of evidence, do you, to determine the cause of the death?

A. By symptoms; now, I mean including the bacteriological test and physical signs that I have mentioned above. I think that that is the only way we have during the life of the patient, of determining the nature of the disease. Of course after the patient is dead we have a still more reliable method.

Q. Isn't it a fact, Doctor, that the attending physician is best able to judge of that matter, or in other words, that the attending physician is best able to judge of the cause of the death or the nature of the disease?

A. It is not a fact when large bodies of statistics are concerned, that the statistics are always as reliable with regard to the causes of death, as the opinions of men who are particularly skilled in internal medicine.

Q. Do you know anything about these different groups of fever in Baltimore prior to 1899?

A. You mean the actual figures?

Q. Yes?

A. I know about the occurrence of cases, but I haven't any figures with me with regard to the years. 11868

Q. Why have you eliminated those figures, Doctor?

A. Because I simply wanted to compare the last three or four years with St. Louis.

Q. Did you ever practice medicine?

A. Yes.

Q. In actual practice?

A. Yes.

Q. Where?

A. I took the practice of my preceptor for a while in the country in Canada during one summer. I practiced medicine in the Toronto general Hospital for one year; I practiced medicine during the three months as head of the children's hospital at Mount Airy, Maryland. I practiced medicine in the Johns-Hopkins hospital the first year that I was there, and I practiced medicine in the Philippines, and in Chicago. I occasionally see interesting and rare cases in consultation.

Q. How long were you in the Philippines?

A. I was in the Philippines from May 5th to some time in July.

Q. That was while you were on this Commission?

A. Yes.

Q. And you practiced then?

A. To a certain extent, yes; I saw especially some sick 11869 Americans who needed attention.

Q. Did you ever make a study of the typhoid statistics in general, as a physician, and as applied to water supplies?

A. In a general way, but not in a particular way. I have never made any publications, or any special research.

Q. You have never made any investigation then but ordinary investigation as an ordinary physician, and as would ordinarily be made by a physician?

A. Upon typhoid?

Q. Yes?

A. Yes, I think my studies were scarcely comparable with those of the average physician. I think they were rather more extensive studies than the average physician makes.

Q. How about your practice?

A. My practice has, I think, been unusually interesting and helpful in developing me scientifically.

Q. Has it been as extensive as the average physician's?

A. If you mean the average physician, who has not a hospital appointment, I should say that it was more extensive.

Q. Doctor, you stated something about the existence of typhoid fever where pure water was used in cities, what do you mean by that, and where were they?

A. I do not recall exactly the statement to which you refer.

11870 MR. TODD: It is the town where filters had been put in.

MR. JEFFRIES: He said protected surface water.

A. I do recall speaking of a few cases of typhoid in Berlin and Munich and Hamburg.

Q. New York and Boston?

A. I have the statistics here of the New York and Boston and Philadelphia typhoid conditions.

Q. Have you this group of fevers in those statistics that you read?

A. No, only typhoid in the statistics I have with me here.

Q. Are those typhoid statistics that you have sufficient to form an opinion as to the sanitary condition of the water supply in New York?

A. Why, they permit me to form an opinion, but of course a limited opinion.

Q. What is it?

A. The statistics I have here, for instance, for New York, and I have two sets of them, are the deaths from typhoid fever in New York from 1870 to 1900, and from the comparative mortality of New York with other cities from typhoid fever, they show a remarkable and interesting decerease in the number of cases, from 1870.

Q. How do they compare with St. Louis, for the last ten 11871 years?

A. Well, from 1890 on, the death rate of New York is lower from typhoid per 10,000 inhabitants—

Q. Is that for ten years or by years?

A. This is by years. They are decidedly lower in New York than in St. Louis.

Q. Now, do you know whether or not this group of fevers, such as intermittent, malarial, etc., have been included in the typhoid fever statistics of Chicago?

A. In the Chicago statistics?

Q. Yes.

A. I think I have the Chicago statistics here.

Q. Do you know whether they have been separated?

A. I don't know; I have not looked up that point.

Q. Did you ever look them up for any other city?

A. I have looked them up for St. Louis and Baltimore.

Q. And that is the sum total of all your investigations?

A. My experience in Baltimore was so interesting in that connection that I have repeatedly spoken in medical societies about the confusion that the physicians make in these two groups.

Q. You think, then, that St. Louis and Baltimore are the only two cities in which this confusion has been made?

11872 A. Not at all. I think it has been made in nearly every city in the country, but more particuarly in southern cities, and I have warned practitioners in medical societies, urging them to more sharply diagnose.

Q. That has been continually practiced right along, in the cities?

A. It has been very much better in some cities than others, where the physicians have been better educated, and where their attention has been particularly drawn to it.

Q. The deduction from that is, that the doctors and physicians in the southern cities are not as well educated as those in the northern cities?

A. That is not a necessary deduction. The incidence of malaria is so much greater in southern cities than in the northern cities, that the opportunity for making the mistake is greater.

Q. What do you know about the distribution of malaria in the Mississippi valley?

A. I have made no especial study about the distribution of the malaria in the Mississippi valley.

Q. What do you mean by the incidence of malaria?

A. The occurrence of cases of infection with malaria.

Q. Is there any more malaria in southern cities--

11873 A. Yes.

Q. And not incidence of malaria?

A. That simply means the number of cases occurring.

Q. So, then, the difference is in the number of cases and not in the locality, to particularly call the attention of the physicians in the localities where the fevers occur, is that it?

A. Well, in the main I think that the difficulty is due to lack of education in modern methods in diagnoses. In some southern cities where the men are better educated with regard to these points, as in Baltimore, the statistics are more reliable, though even in Baltimore there are so many physicians who cannot make a correct diagnosis, that the statistics are still very faulty, I am sure.

Q. Well, now, is it your opinion, Doctor, that physicians generally are not able to make a correct diagnosis unless they be specially learned in the different specialties covering these different diseases?

A. I think that it is very easy for a physician who can examine blood microscopically, and who can make the Widal reaction, or have it made for him, to make a mistake.

Q. And that is in cases where the person dies?

A. No, where they live, too.

11874 Q. Well, how would it be where the person dies, would they be able to make a correct diagnosis?

A. At autopsies?

Q. Yes?

A. Very few physicians are able to make correct diagnoses at autopsies. A man must be a pathologist.

Q. Without an autopsy can they?

A. After death?

Q. Yes?

A. I think it would be very hard.

Q. In case of fevers?

A. You mean, if he could not diagnose during life, could he make one after death, without an autopsy?

Q. Yes, so far as malarial fever is concerned?

A. I don't see how he could.

Q. What relation does malarial fever bear to water supplies?

A. The relations of the water supply to a mosquito would be the only relation so far as the drinking water is concerned. There is absolutely no relation to malaria.

Q. A water that is used for domestic purposes, then, has no bearing?

A. No bearing whatever.

Q. Do you care to go on record as saying that a mosquito is the only thing that produces malaria? 11875

A. I am willing to go on record as saying that there is no evidence that malaria is ever obtained by human beings except through the bite of a mosquito.

Q. And that is the only way it can be obtained, and if there were no mosquitoes there would be no malaria?

A. In my opinion there would not.

Q. How do you explain the malaria in the Rocky Mountains in the west, and in Blue Ridge?

A. If there was no mosquito there, there would be no malaria.

Q. Suppose that you were told that there was malaria there and no mosquitoes?

A. I would not believe it, and I am sure that if I went there and examined the field there would be mosquitoes about there.

Q. Don't you know as a matter of fact that there is malaria in those mountains, and that there are no mosquitoes?

A. While there are no mosquitoes there, there are mountain fevers and mountain fevers.

GENERAL CROW: There is but one mountain fever.

A. There are several mountain fevers that have been described, and they may not be all identical, but there is no malaria without the mosquito so far as we know, and we know a great deal about it now. 11876

MR. JEFFRIES: And the mosquitoes are liable to be more prolific in stagnant water than in running water, are they not? isn't that true?

A. Yes. Little bits of pools are more responsible than great bodies of water. A little hole in a stump is often a breeding spot for enormous numbers of mosquitoes, a little pool near a well, near a cistern, and if we could do away with these little breeding pools we would do away largely with mosquitoes and with malaria.

Q Doctor, is malarial fever as a general proposition regular from one year to another in a community?

A. It appears to be in some communities tolerably regular.

Q. Don't you know in the Mississippi valley for the last three years, there has been very little malarial fever for the Mississippi valley?

A. The letters I have had from a doctor in St. Louis have not said anything about that. He told me that malaria was occurring all the time.

GENERAL CROW: Who was that doctor?

A. Dr. Roland Hill. He was a fellow interne with me in the Toronto General Hospital in 1890.

11877 MR. JEFFRIES: You don't know whether it is or not, occurring regularly from year to year?

A. From my own personal observations?

Q. Yes. In the Mississippi valley around St. Louis and in St. Louis?

A. Not from personal knowledge.

Q. I will ask you if these tables which you have read in evidence do not indicate that there has been a falling off in malarial fever?

A. They do not to me.

Q. I will ask you if the tables on their face in the health report,—taking it for granted that they were correctly reported, which you have no reason to doubt—

A. No.

Q. —does not indicate that there was a falling off in malarial fever, and I want to ask if you mean by that to impeach the integrity of the physicians of St. Louis?

A. I do not mean to impeach the integrity of the physicians of St. Louis, but I do mean to intimate that there have been improper diagnoses made in the city of St. Louis.

Q. Doctor, do you know of your own knowledge or from any information which you have received, that you can 11878 state in evidence here, that there has not been a falling off in the typhoid malarial cases in the city of St. Louis in the Mississippi and Missouri valleys, in the last three years, as compared to what it was three, four, five or six years prior thereto?

A. My answer to that would be—I have here the statistics of two groups of cases from St. Louis, typhoid fever and the so-called remittent, intermittent, typho-malaria, congestive and simple continued fever—

Q. But, Doctor, those groups apply to different periods, do they not, one group from 1900 down, and the other, 1900—

A. I have divided them.

Q. Now, then, you don't know that there has been or has not been a falling off of malarial fever cases in the Mississippi valley, the Missouri valley, and in the city of St. Louis in the last three years, or since 1899, do you?

A. I do know that malaria has caused no such death rate at any time as is reported by the column headed "Remittent, intermittent, typho-malarial, congestive and simple continued fevers."

GENERAL CROW: That does not answer the question. You must answer the question.

(Question repeated.)

11879 A.. I have no definite information on that point.

Q. Now, have you any personal knowledge of the intermittent and the continued fever, as to whether it has increased or decreased?

A. I know that no disease should be classed under that name at present, it is a misnomer.

Q. And that means one or two things?

A. No, not always, but one generally; one of two things, either typhoid or malaria. There are very few deaths from malaria, and one can say from his knowledge of malaria and typhoid, that the deaths in that column were due chiefly to typhoid. Some of them to other things like dysentery, acute tuberculosis, but scarcely anything would be termed really malaria, which the terms remittent, intermittent, typho-malaria, and simple continued, indicate.

Q. Doctor, have you noticed any increase in the typhoid death rate in St. Louis for the year 1902, as compared with that of the years 1900 and 1901?

A. The reported death rate from typhoid alone in St. Louis, that is in the group under "typhoid alone" in the city health reports, is 27.90 per 100,000 in 1900, and is 34.90 for 1901. The figures for 1902 are 36.7. But on comparing the total 11880 cases, or taking the total cases of deaths from the two groups together, typhoid fever and that other group,—remittent, intermittent, typho-malaria, etc., the number of deaths in 1900 is 280—168 in the typhoid fever group; 112 in the other group.

In 1901 the total number of deaths from the two groups together is 278, of which 198 are in the typhoid fever column and 80 in the remittent, intermittent, typho-malaria, congestive and simple continued fever column.

In 1902, the total number of deaths of the two together, was 324, of which 222 were typhoid alone and 102 in the remittent, intermittent, etc., column.

Q. So there has been an increase in the typhoid alone?

A. In 1902 over 1900 and 1901.

Q. Yes, in other words there is an increase in 1901 over conditions existing in 1900?

A. No. There is in typhoid alone, but not in the two groups together.

Q. In typhoid alone?

A. Yes, but in 1902 there is a distinct increase in typhoid alone, and in the combined groups.

Q. And in the combined?

A. Yes.

Q. How do you explain that increase, Doctor?

11881 A. The increase is not so great but what it might be—it might occur in any year. For instance, if you examine the statistics further back, you find in the years 1890 and 1891, 1892, 1893 and 1894, more cases in the combined group.

Q. Then, Doctor, attributing the typhoid in all instances to the pollution of the water supply, it simply means that the conditions in the water are not the same from year to year, although the source of the water supply is the same, is that true?

A. That is true.

Q. And the water at the intake is different one year from what it would be another year?

A. Assuming that all the deaths are due to water pollution?

Q. Yes?

A. It would indicate either that there were differences from year to year in the pollution of the water supply, or that for some reason or another the people were more susceptible one year than another.

Q. But as an epidemiologist now, which would be considered as most likely to occur?

A. There is a third possibility, if I may mention it, and

that is that there might be just the same degree of pollution,
but the bacilli might be more virulent in one year than
11882 in another, corresponding to the cases from which they
had been derived. I don't think that it would be easy to
say where the difference is so slight as it is here, which factor
was most concerned.

Q. But it would be one of the factors, and as likely to be one as another?

A. In my opinion it would be, yes. I would be inclined to lay more weight on the water pollution than on the other two factors.

Q. Doctor, do you know what towns or cities are situated on the Mississippi river watershed, which includes both the Missouri and the Illinois rivers, above the chain of rocks, that have a population of more than 5,000 inhabitants, and that are within seventy-five miles of St. Louis?

A. If I may refer to those statistics that I have already put in.

Q. Yes,—well, I will ask you this question, Doctor, isn't it a fact that Alton and St. Charles are the only towns of that size, and that St. Charles has not a complete sewer system, and that Alton also is not completely sewered? In other words, a very large portion of both of those towns is unsewered?

A. I understood that St. Charles poured some sewage into
the river, and that typhoid was occurring in St. Charles,
11883 and that seemed to me very important in connection—

Q. Is it your understanding, Doctor, that the typhoid fever in St. Charles has been occurring in more than normal conditions for the last six years?

A. I have no information about that.

GENERAL CROW: You fix no time?

A. I can fix no time, no.

MR. JEFFRIES: And you have no information on that subject that it was prevalent in St. Charles any more than its normal condition for the year 1902?

A. You mean more than its average condition?

Q. Yes?

A. I have no information on the point except what is on those statistics that I have introduced.

Q. Of 1900 and 1901?

A. No.

Q. Or that there was more typhoid in St. Charles in 1902 than there was in 1901 or 1900?

A. I have no information on that.

Q. Now, does your information with reference to Alton correspond with the information that you have with reference to St. Charles?

A. I have no information with reference to Alton.

Q. You have no information with reference to Alton?

11884 A. No, but I would say that if typhoid were occurring in those two towns and the sewage was being poured into the river and those two towns are within seventy-five miles of St. Louis, I should think a slight difference in the number of cases in two or three years in St. Louis, might easily occur without any change in the amount of typhoid being put into the river.

Q. Now, Doctor, I will ask you this question: if you consider that the sewage from St. Charles and from Alton, which are the only towns on the Mississippi river watershed above the chain of rocks within seventy-five miles of the chain of rocks, do you consider that those towns are the source of all the objectionable pollution in the Mississippi river at the chain of rocks?

A. I would not at all suppose that the towns must necessarily have 5,000 inhabitants in order to pollute the water. I think a single typhoid case occurring near the intake in a village or a hamlet of twenty houses, would be more significant; much more significant than the sewage from a town of 5,000 a great deal further away.

Q. Even if there were no sewers?

A. If the excreta from the typhoid patient got into the river in any way.

Q. But that, Doctor, would come in the shape of epi-
11885 demics, would it not, being so close to the city that it would not be continuous?

A. I regard typhoid fever as being epidemic in St. Louis all the time; not a great epidemic, but still, epidemic.

Q. Have you ever examined the distribution of typhoid deaths in St. Louis by the months?

A. Yes, part of my statistics were based on adding up those together.

Q. Do you know anything about the typhoid conditions in St. Louis this year, 1903?

A. I have looked over the pamphlets that come out, giving the statements, but I have not them with me.

Q. And you haven't included them in your statement in evidence with reference to those dates?

A. No.

Q. Do you know, or don't you know, that St. Charles and Alton are the only towns that are sewered and situated upon the Mississippi river and its tributaries within one hundred miles of St. Louis, and that contain as much as 5,000 population?

A. I did not—I do not know the cities; I don't know the number of cities of that population. I am not familiar with that.

Q. I will ask you, Doctor, if there would not be more
11886 typhoid in St. Louis if this water was taken absolutely
in its raw condition from the river at the chain of rocks,
before it went into the settling basins of the water supply of the city?

A. May I ask about those settling basins? I am not familiar with them. How many are there and what is the arrangement?

Q. Well, the water remains in these settling basins from two to three days.

GENERAL CROW: There are four of them at one place and two in another.

A. I should think if the settling basins were properly conducted that they would diminish the typhoid bacilli.

MR. JEFFRIES: You don't know, then, how much sedimentation is effected by them?

A. No.

Q. You have not considered that, have you, in your statements in evidence with reference to the typhoid situation in St. Louis?

A. I have not considered the water to any great extent below the Illinois river, because I did not deem it necessary in the case.

Q. Doctor, have you ever examined an anthrax epidemic?

A. In human beings?

Q. Or in stock?

11887 A. I have never examined an epidemic. I have made
an autopsy on one human case of anthrax, and of course

on a number of animals, in the laboratory, dead of experimental anthrax.

Q. Those examinations were made upon the dead body and not with reference to any examination of an epidemic?

A. No.

Q. And causes of the epidemic?

A. Well, in the animals we caused it ourselves by experimental inoculation.

Q. Anthrax is a spore forming bacilli, is it not?

A. Anthrax forms spores.

Q. Do you know how long they will live in water or in earth?

A. I cannot give you the exact length of time, but I know that they will live a very long time; that they are most resistant.

Q. I will ask you if they won't live as spores from three to seven years or more?

A. I think that they will live at least years when they are kept dry.

Q. And also wet?

A. If they were wet I should think they would grow out into bacilli—the spores would grow out into bacilli.

11888 Q. They would not grow out into bacilli if they were wet unless the moisture in which they were placed reached the proper temperature, would they?

A. No, if the temperature were at the freezing point I should not think they would grow out.

Q. In other words, as long as they remained in water or in earth and did not get into the proper media as to temperature, they would not grow out into bacilli?

A. Unless they had the proper temperature and media, they would not grow out into bacilli.

Q. Have you had any experience in examining the causation of tetanus?

A. Yes, I have worked with the tetanus bacillus, and with experimental tetanus inoculations, and I have studied human cases of tetanus.

Q. The germs of tetanus form spores, do they not?

A. They do.

Q. And how long will they live?

A. They, too, will live a considerable length of time; I don't know how long; they are very resistant.

Q. From one to three years or longer?

A. I don't know; they are present in garden earth all the time.

Q. And very resistant?

11889 A. And very resistant.

Q. Doctor, do you know, or, rather, isn't it a fact that scientists have recently discovered that the germs of tetanus are prevalent in the intestines of all cattle?

A. I know that they are present in the intestines of animals. I am not sure about particular animals; and they are present in the earth, in the soil, very widely distributed.

Q. Isn't it a fact that some scientists of recent date have taken the position that they are the natural inhabitants of the intestines of cattle?

A. I am not familiar with that point; it may be true.

Q. It may be rue?

A. That might be true. I would not be surprised if it were true.

Q. Then, if they are the natural inhabitants of cattle, the offal and washings from stockyards and slaughter pens at Chicago, discharged into the drainage canal—is there any reason that you know of, Doctor, why they would not be carried down the Illinois river?

A. I know of no reason why they might not, along with the tetanus bacilli of thé soil on the banks of the river all the time.

11890 Q. That would be an additional source?

A. An additional source.

Q. Of tetanus spores?

A. I think those spores would grow out into bacilli under favorable conditions.

Q. That is, if the proper temperature and the proper media was obtained?

A. Yes, but tetanus is not a water-borne disease, as far as I know, in human beings.

Q. Anthrax is though, is it not?

A. I have always associated anthrax with contact in skin infection, although feeding experiments in animals will produce anthrax infection.

Q. Well, may it not be produced either way?

A. In animals, yes; whether or not enough of it could be introduced into a human being by the alimentary tract to set up anthrax, I am not prepared to say.

Q. You are not prepared to say because no experiment has ever been made?

A. I know of no experiments.

Q. Now how is tetanus contracted?

A. Generally by a wound of the skin, a deep wound of the
skin; inasmuch as the bacillus is anaerobic, it does not
11891 grow and survive in the air.

Q. I will ask you, doctor, if the germs of tetanus were discharged into the canal at Chicago by means of the sewers of Chicago, and find their way down the Illinois river to St. Louis, and carried into the intake, and thence into the water supply of the city, and a house servant should be washing vegetables or cleaning vegetables with the water drawn from the tap, and should accidentally inflict a wound in her finger, or in her hand and one of those tetanus spores be carried into the wound, if it would not cause the disease?

A. There would be a thousand chances that in such a case the infection came from the dirt on the vegetables, to one chance that it came from the river water.

Q. The opportunity, however, would be there, would it not?

A. I have never known of a case occurring from water-borne bacilli of tetanus.

Q. In the cases that you have known, how were you able to determine whether it came from the earth or from the water?

A. By far the majority of the cases of tetanus are Fourth of July tetanus cases, due to injury of the hand with a toy pistol, and it has been shown that the percussion caps connected with those toy pistols are very frequently infected with tetanus;
and other cases, nearly all, are punctures with rusty nails
11892 of the bare feet,—children going bare-foot, with dirt on
their feet and getting a puncture wound.

Q. Could not a rusty nail be moistened in water from a sprinkler drawn from the water supply, and a tetanus germ carried in that water?

A. I don't think there is any evidence in favor of that theory.

Q. It is possible, is it not?

A. I would not deny the possibility of it, but I think it very improbable.

Q. Well, is it not as probable that it should be carried that way as to be carried by the dirt in the earth?

A. No, not nearly.

Q. Do you know whether or not there has been the germs of spores of tetanus found in the waters of the Illinois river since the opening of the canal?

A. I don't know; I should think it very probable that there might.

Q. Do you know whether or not the germs of anthrax or the spore of anthrax has been found in that water since the opening of the canal?

A. I have not heard of its being found.

Q. And would you be surprised if you should hear that?

11893 A. Yes I would, because the anthrax is the least resistant when it is not in a spore form,—of any of the bacteria almost; it is killed off more easily than most any other form when it is not in spore condition.

Q. But in its spore condition would you be surprised at its being found in the water of the Illinois river?

A. I would not expect it to be found in spore condition, because I think the spores would grow out into the less resistant bacilli in the water.

Adjourned.

11894

Chicago, Illinois, November 9, 1903.

STATE OF MISSOURI
vs.
THE STATE OF ILLINOIS AND THE SANITARY DISTRICT OF CHICAGO.

It is hereby stipulated and agreed between Samuel B. Jeffries, respresenting the State of Missouri, and James Todd, representing the State of Illinois and the Sanitary District of Chicago, that the testimony of C. D. Cassingham, Frank L.

Stevens, and Walter G. Sackett may be taken before Fred A. Burton, a notary public in and for Cook county and State of Illinois, and they may give their testimony in the case of the State of Missouri vs. The State of Illinois and the Sanitary District of Chicago, and be examined and cross-examined in the same manner and to the same effect as if said testimony was taken before Frank S. Bright, Commissioner of the United States Supreme Court.

And it is also stipulated and agreed that said testimony when so taken and reduced to writing, may be incorporated in the record of this case, with the same force and effect as though the same had been taken before Commissioner Frank S. Bright.

11895 C. D. CASSINGHAM,

called as a witness in behalf of the defendants, after first being duly sworn, was examined in chief by Mr. Todd and testified as follows:

Q. What is your name?

A. C. D. Cassingham.

Q. Where do you live?

A. Wilmington, Illinois.

Q. Mr. Cassingham, did you ever collect any samples of water from the Kankakee river?

A. Yes sir.

Q. When did you collect those samples?

A. I cannot give the dates, I kept no record of it.

Q. About when.

A. About the year 1899 was the first I think.

Q. Did you collect any in 1900?

A. I think I did, yes sir.

Q. For whom did you collect those samples?

A. Professor J. H. Long.

Q. From what river did you collect the samples of water?

A. The Kankakee.

Q. At Wilmington, Illinois?

11896 A. At Wilmington.

Q. In what manner did you collect the samples?

MR. JEFFRIES: I object to the testimony with reference to the taking of samples in the Kankakee river for the same reasons stated in my previous objections to the taking of samples in the tributaries of the Illinois river.

A. They were collected at that time. I was a teamster or drayman and I drove right out into the river so that I could reach the water. I collected it in a bottle. I put my hand over the mouth of that bottle until I got it down probably a foot below the top of the water and then I filled the bottle.

Q. Which side of the wagon did you collect it, up stream or down?

A. The upper side of the wagon,—up stream.

Q. Where did you get the bottle from?

A. That was sent from Mr. Long to me.

Q. By express?

A. By express. I got them out of the express office.

Q. Were the bottles sealed when you received them,—I mean stoppered. Was there a stopper in the bottles?

A. Yes sir, and sealed after the water was taken.

Q. Now after you received the bottles with the stoppers—
11897 what sort of a stopper did the bottles have in them?

A. What did they have in them?

Q. What sort of a stopper, cork or glass?

A. I think it was glass.

Q. Now after you got the bottles and went out into the river, did you remove the cork or the stopper from the bottle before you submerged the bottle under the water?

A. Yes, I took the stopper out before I submerged it under the water.

Q. After you had filled the bottle, in the manner you have indicated, you put the stopper back in, did you?

A. Yes sir.

Q. After you put the stopper back, what did you do with the sample of water collected?

A. After I corked the bottle, a piece of cloth,—I think it was cloth—was put right over this stopper and I tied a string around it and sealed it, and I took a tag with directions as to the temperature of the air and the water and delivered it to the expressman at Wilmington.

Q. How long from the time of taking the water was it, before the sample was delivered to the expressman at Wilmington?

A. Probably twenty minutes or half an hour at the outside.

Q. Now, on the tag that you used, will you describe that
11898 tag clearly and briefly?

A. Why the tag was probably a little longer than that (indicating), probably that width, in the shape of a common shipping tag that is used by business men.

Q. Give it in inches?

A. It was probably two and a half by three and a half.

MR. TODD: It is agreed that the cards used on these samples of water by this witness, are the same kind of a card and envelope as has been testified to here by other witnesses, as being attached to all samples of water collected by Professor Long.

Q. How often did you take these samples of water?

A. I think it was twice a month; I don't know the number of months.

Q. Well your card should show the number of samples taken?

A. Yes sir.

Q. And the date of the taking?

A. Yes sir, and the temperature.

CROSS-EXAMINATION,

By Mr. Jeffries.

Q. Where were the samples taken from?

A. Wilmington, Illinois.

Q. How deep was the water in the Kankakee at that time?

11899 A. It would vary from a foot and a half to three feet.

Q. How many samples did you take?

A I couldn't tell; I kept no record of it.

Q. About how many,—three or four?

A. A great many.

Q. What part of the year, what time of the year?

A. It might be the first or second—about August I think, I am not positive.

Q. When did you finish?

A. I think probably the first year I collected only about three different months.

Q. Did you take any other samples than those in the large bottles?

A. Yes, one small bottle.

Q. How did you take them? In the same way?

A. In the same way.

Q. You pulled the cork out, put your hand over the mouth of the bottle and submerged it?

A. Yes sir.

Q. About a foot?

A. Yes, about a foot below the surface.

Q. Then you removed your hand and let the bottle fill with water, then you drew it out of the water and put the cork back in?

11900 A. Yes sir.

Q. You did that with both large and small?

A. The same, both with the large and the small.

Q. Did you rinse the bottles?

A. Yes sir, I did.

Q. How did you do that?

A. By submerging them, taking them out and shaking the bottle.

Q. What did you do with the cork while you were rinsing the bottle?

A. Laid it on the wagon until the bottle was rinsed and filled.

Q. What kind of a wagon was it?

A. It was a dray, something similar to those used in Chicago, or stake wagons, some call them.

Q. Did you lay it down in the bottom of the wagon?

A. Yes, laid it down in the bottom of the wagon.

Q. Have any particular way of laying it down?

A. No sir.

Q. The bottom of the wagon was dirty wasn't it, or dusty?

A. No sir.

Q. There was dust lying around?

11901 A. Probably some dust. I didn't wash it off.

Q. You didn't wash it off.

A. No sir.

11902 **FRANK L. STEVENS,**

called as a witness in behalf of the defendants, being first duly sworn, was examined in chief by Mr. Todd, and testified as follows:

Q. What is your name?

A. Frank L. Stevens.

Q. Where do you live?

A. Raleigh, North Carolina.

Q. What is your business?

A. Teaching.

Q. Where?

A. At the Agricultural-Chemical College of Raleigh.

Q. Where were you before you went to Raleigh, North Carolina?

A. I was in Europe.

Q. And before going to Europe?

A. At the University of Chicago.

Q. Are you acquainted with Professor E. O. Jordan of the University of Chicago?

A. Yes sir.

Q. Did you ever do any work under the direction and supervision of Professor Jordan of the University of Chicago?

11903 A. Yes sir.

Q. Where?

A. At the University of Chicago.

Q. In connection with the analyses of water?

A. Yes sir.

Q. What position did you occupy in the laboratory there, Mr. Stevens?

A. I was Professor Jordan's Assistant in the chemical work.

Q. Covering what period were you there?

A. Beginning in the spring of 1899, until the summer of 1900.

Q. While in the laboratory there under Professor Jordan did you receive samples of water which came there by express from the express company?

A. I did, yes sir.

Q. How were those samples of water marked or labeled?

A. There was a piece of rubber cloth covering the stopper, and that cloth was wired and sealed, and the tag was fastened on with the same wire.

Q. Was that a tag that had printed on it Sanitary District of Chicago; Streams Examinations?

A. I couldn't tell without identifying the tag.

MR. TODD: It is agreed that the cards on these samples were the same kinds of cards that have been testified 11904 to and introduced in evidence here by the different witnesses who collected the water, and sent them to Professor Jordan of the Chicago University.

Q. Now after you received this water, what was done with it?

A. It was opened. The bottle was opened and the water was analyzed.

Q. Did you keep the tags?

A. Yes, we kept those as long as I was in the laboratory.

Q. And they were turned over to Professor Jordan?

A. Yes sir.

Q. And under his control and supervision?

A. Yes sir.

Q. And you only had to do with the chemical samples?

A. Yes sir.

Q. And did those samples extend from St. Louis up to Bridgeport, received from the different water collectors that have been heretofore examined in this case?

A. Yes sir.

Q. Now after taking those samples or receiving them there, they were turned over to Professor Jordan, were they not, I mean under his superivision. The samples came in under his supervision?

A. After they got in the laboratory, yes.

Q. You worked under his direction and supervision?

11905 A. Yes sir.

Q. And was the work that was done by you done under the direction and supervision of Professor Jordan?

A. Yes sir.

Q. And was that all done correctly in accordance with his directions and instructions?

A. Yes sir.

Q. Who was assisting you there? I mean who was working with you in that work?

A. Mr. W. G. Sackett.

Q. How long was he working there?

A. I think it was from October until I left the work.

Q. He was working under the direction and supervision of Professor Jordan at the time?

A. Yes sir.

Q. And Professor Jordan was in the laboratory there?

A. Frequently or constantly.

CROSS-EXAMINATION,

By Mr. Jeffries.

Q. When did you say you commenced this work?

A. It was in the neighborhood of the first of April, 1899.

Q. And how long did you work there?

A. Until in the neighborhood of June, 1900.

11906 Q. Now what was the character of your work, bacterial or chemical?

A. Purely chemical.

Q. Did you undertake to make a complete chemical analysis for all chemical constituents in the water?

A. No sir.

Q. What particular constituents did you look for?

A. We analyzed for the turbidity, sediment, color, odor, total residue on evaporation, dissolved residue on evaporation, suspended residue on evaporation, chlorine, total oxygen consumed; dissolved oxygen consumed; suspended matter, oxygen consumed; nitrogen as free ammonia and nitrogen as albuminoid ammonia; total, dissolved, suspended; nitrogen as nitrites and as nitrates. I think that was all.

Q. The other chemical constituents—are there other chemical constituents in these samples of water, that were not taken?

A. Yes sir.

Q. Of what character?

A. The inorganic matter. We did not analyze for the magnesia calcium and other things.

Q. That is the inorganic?

A. Yes sir.

Q. You were a student in the University of Chicago?

11907 A. Yes sir.

Q. How soon after these samples came into Professor Jordan's office were they analyzed?

A. The analysis was in nearly every case begun the same day they came in.

Q. What part or relative quantity of the water in these large bottles did you examine and analyze?

A. Why, I suppose we would use three-quarters of what was contained in the bottle.

Q. But you wouldn't determine the chemical constituents of any particular part of the water in its entirety?

A. Yes, we filtered it and we analyzed the filtrate. We analyzed the water unfiltered also.

Q. But you would use a certain quantity of a sample of water for one particular analysis or determination, and then another part for other determinations?

A. Yes sir.

Q. You would shake the bottles before you commenced the determinations?

A. The bottles were checked—did you say checked?

Q. I said shaken?

A. Yes sir.

11908 Q. You would determine the turbidity of the water by observing the sediment in the bottom of the bottle, or by disturbing it?

A. The turbidity was determined after it had settled.

Q. After it had settled?

A. Yes, and we determined also the sediment.

Q. Both in the same way?

A. Yes. The turbidity was due to the part that didn't settle; the water after the sediment had formed.

Q. How long had you been engaged in this character of work before you commenced to do this particular work for Professor Jordan?

A. I had been teaching chemistry and studying chemistry for ten years I suppose.

Q. And are still doing so?

A. No, I am not working in chemistry now.

11909 WALTER GEORGE SACKETT,

called as a witness in behalf of the defendants, being first duly sworn, was examined in chief by Mr. Todd, and testified as follows:

Q. What is your name?

A. Walter George Sackett.

Q. Where do you live?

A. Raleigh, North Carolina.

Q. What is your business?

A. Teacher.

Q. Where?

A. Baptist Female University.

Q. How long have you been teaching there, professor?

A. This is my second year.

Q. Where were you before going there?

A. University of Chicago.

Q. How long were you in the University of Chicago?

A. Three years and a half.

Q. Did you ever do any work under Professor Jordan in connection with stream examinations?

A. Yes sir.

Q. In what department?

11910 A. I was under him in chemistry and also in bacterial work.

Q. How long were you in the chemistry work?

A. In the chemical work from October 1st, 1899 to the end of the work.

Q. And was Mr. Stevens with you in that work part of the time?

A. Yes sir.

Q. Now confining yourself to the chemistry work. Did you receive any of the samples of water that were sent to the laboratory from the different water takers?

A. Yes sir.

Q. Who else received samples there besides yourself?

A. Dr. Stevens.

Q. When Mr. Stevens didn't receive them you did?

A. I did.

Q. Nobody else received them but you two?

A. That's all.

Q. They were received in the manner in which Mr. Stevens just testified.

A. Yes sir.

Q. And they had a card attached to them such as we have stipulated they had?

11911 A. Yes sir.

Q. Did you work under the direction and supervision of Professor Jordan in this chemical work?

A. I did.

Q. And in that ascertainment, you made the same ascertainments that were made by Professor Stevens, as he testified a few moments ago?

A. I did.

Q. When did you start in the bacteriological work?

A. It was in October of 1901.

Q. Where?

A. St. Louis.

Q. Did you have a laboratory in St. Louis?

A. Yes sir.

Q. And that was a laboratory established by Professor Jordan?

A. Yes sir.

Q. And where was that laboratory located?

A. Eleventh and Locust.

Q. What was the number there?

A. 1023 Locust Street.

Q. And that was what year?

A. 1901.

Q. Was this laboratory established for the analysis of 11912 samples that had been agreed on to be taken at certain points by the State of Missouri and the defendants in this case together?

A. Yes sir.

Q. And how long did you work there?

A. Until about the 16th of January,—three months.

Q. And where were the samples taken from which you analyzed in that laboratory?

A. There were four from the Mississippi river, chain of rocks; one from Bellefontaine in the Missouri river.

Q. Who took those samples?

A. Mr. Cullon took them from the Mississippi river and Mr. Egan from the Missouri river.

MR. TODD: Those are the water takers that we have stipulated in regard to their testimony, Mr. Jeffries.

MR. JEFFRIES: All right.

MR. TODD: Q. How many samples of water were taken?

A. Five.

Q. How often were they taken?

A. Every day except Sundays.

Q. And at what points in the Mississippi river were those samples taken?

A. There was one sample taken from the Missouri shore;
11913 one from the Illinois shore; one from mid-stream; one
from the intake tower, and one from Bellefontaine in the Missouri river.

Q. Where was the sample from at Bellefontaine, Missouri, did it purport to be taken from the Missouri river at Bellefontaine?

A. That's right.

Q. Did you ever personally visit the chain of rocks?

A. Yes sir.

Q. Did you see the samples collected?

A. Yes sir.

Q. Was there any work done at the chain of rocks?

A. Yes sir.

Q. Where; at what point at the chain of rocks?

A. We had a laboratory fixed up at the chain of rocks where the plating was done.

Q. Was anybody else working on the samples there at the same time, with you?

A. Yes sir.

Q. Who?

A. Mr. Damon for St. Louis.

Q. He was representing St. Louis?

A. Yes sir.

Q. And this work was being done in the same room, together?

A. Yes sir.

11914 Q. This laboratory was the St. Louis laboratory at the chain of rocks, wasn't it, fixed up there?

A. I think it was mutually agreed that we were to use the same room; it was the property of the St. Louis waterworks.

Q. It was extended to us by courtesy of St. Louis, the use of that room?

A. Yes sir.

Q. These samples were then taken where?

A. After I had made a bacteriological analysis, as far as the plating was concerned, they were taken back to the St. Louis laboratory.

Q. And then the work was completed there?

A. Yes sir.

Q. Under the direction and supervision of Professor Jordan?

A. Yes sir.

Q. How long after the samples of water were taken out of the river was it before they were plated?

A. Immediately.

Q. And at Fort Bellefontaine?

A. About an hour.

Q. There would be an hour between the time of taking the sample and the plating of the samples?

A. It would require that long to come from Bellefontaine to St. Louis.

11915 Q. How many samples of water were taken and analyzed at that laboratory?

A. 280 I believe.

Q. And was this work done under the direction and supervision of Professor Jordan?

A. Yes sir.

Q. And these results that were obtained there, have all been turned over to Professor Jordan?

A. Yes sir.

Q. You were simply doing detail work in connection with this, under his direction?

A. Yes sir.

Q. And where else did you do any work, Mr. Sackett, except at the laboratory at Chicago in chemistry, and the laboratory in St. Louis?

A. Do you mean as far as student work is concerned?

Q. In connection with this investigation?

A. At the chain of rocks, St. Louis.

Q. Those were the only three places that you did any work under Professor Jordan in connection with this inquiry?

A. Yes sir.

11916

CROSS-EXAMINATION,

By Mr. Jeffries.

Q. How long did you work with Professor Jordan here in Chicago in that particular work?

A. From October, 1899, until the end of June of the next year, in the chemical work. From October, 1901 to the end of that year on the bacterial work in St. Louis.

Q. Now what part of the bacteriological work did you do here in Chicago?

A. None at all.

Q. It was all chemical?

A. Yes sir.

Q. What part of the bacteriological work did you do in St. Louis?

A. All of it.

Q. At the chain of rocks?

A. All of it.

Q. Now what was the character of that work with reference to the ascertainment of certain facts?

A. At the chain of rocks, the work was entirely quantitative work, in which we plated samples. In the St. Louis laboratory we plated the samples from Bellefontaine for quantitative determinations, and we made analyses of all five samples 11917 for gas fermentation, and the determination of the presence of coli communis.

Q. That was the extent?

A. As far as I was concerned.

Q. Was anyone else working there for you at St. Louis, working with you, for Chicago?

A. Mr. Ernest E. Irons.

Q. Did Mr. Irons work under you or you under him, or were you working together?

A. We were working together.

Q. Were the St. Louis people working at the chain of rocks with you?

A. Yes sir.

Q. And also at the laboratory in St. Louis?

A. Not in our laboratory.

Q. You say you turned over the results of all these analyses to Professor Jordan?

A. Yes sir.

Q. And those results contained the number of bacteria per cubic centimeter?

A. Yes sir.

Q. Together with the presence of coli communis?

A. Yes sir.

11918 Q. And the gas-producing bacteria?

A. Yes sir.

Q. But nothing else?

A. Those sheets also have a record of the turbidity as recorded by the collector and the temperature of the air and the temperature of the water.

Q. You say the collector would record the turbidity?

A. Yes sir.

Q. And you incorporated that into your record?

A. Yes, it was a blank form the same as we have here (indicating paper).

Q. You used the report of the collector in determining the turbidity, and in making your determinations?

A. I made determinations myself, but merely copied his record on turbidity. That is, for the bacterial sample, I am speaking for the St. Louis work entirely.

Q. You made no determinations for the turbidity of the water yourself?

A. Not in St. Louis.

Q. Or at the chain of rocks?

A. No sir.

Q. You did chemical work there too, did you?

A. No sir.

11919 Q. Bacterial only?

A. Yes sir.

Q. Did anyone that was with you do chemical work?

A. No sir.

RE-DIRECT-EXAMINATION,

By Mr. Todd.

Q. Did you take off any of the coli communis from the plates and send them to Chicago?

A. No sir.

Q. You don't know whether Mr. Irons did or not?

A. Mr. Irons did.

Q. He handled that end of it?

A. Yes sir.

ADJOURNED until 2:00 P. M. same day.

2:00 P. M., Monday, November 9th, 1903.

11920 Continuation pursuant to adjournment.

Present, same as before.

MR. TODD: It is hereby agreed between counsel on both sides that the samples of water taken from the upper Kankakee river near South Bend Indiana, by George W. Van Benschotten, as stated by Professor Long in his testimony, were taken in the manner described by Professor Long as near as may be, and that the samples of water taken from the upper Desplaines river near Libertyville, by Mr. Clare Sherman, were taken as stated by Professor Long in his testimony and in the manner therein stated as near as may be, and that the samples of water taken from the upper Fox River at McHenry, as shown by the testimony of Professor Long, were taken by Dr. Charles F. Fegers in the manner described by Professor Long, as near as may be, and that the samples of water taken from the Mackinaw River at Kappa, and analyzed and used by Professor Long in his testimony, were taken by Dr. R. E. McKenzie in the manner described by Professor Long as near as may be, and that the samples of water taken from the upper Sangamon at Mahomet by Dr. John H. Gardiner were taken in the manner described by Professor Long as near as may be, and that the production of said witnesses is hereby waived.

11921 These facts are to be considered in evidence, the same as though said persons had been sworn and their testimony produced in evidence, subject to the objections of the complainant in this, to wit: that the taking of samples of water and the analyses of those samples from the tributaries of the Illinois river, is incompetent, irrelevant and immaterial and has no bearing upon the issues involved in this case.

ADJOURNED.

10:00 A. M., Monday, March 14, 1904.

11922 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

THEOBALD SMITH

a witness on behalf of the defendants, being duly sworn by the Commissioner, testified as follows:

Direct Examination

By Mr. Todd:

Q. What is your name?

A. Theobald Smith.

Q. What is your business?

A. Professor in the Harvard Medical School and Pathologist of the State Board of Health of Massachusetts.

Q. How long have you been connected with the State Board of Health of Massachusetts?

A. Since 1895.

Q. What did you do prior to that?

A. I was bacteriologist and in charge of the investigations in the Department of Agriculture at Washington upon infectious diseases of animals.

Q. How long were you engaged in that work?

11923 A. And if you will allow me—at the same time I was professor in bacteriology in the Columbian University, Medical Department at Washington, D. C.

Q. What institution are you a graduate of?

A. Cornell University and Albany Medical College.

Q. When did you graduate from Cornell?

A. 1881.

Q. After graduating from Cornell what did you do?

A. I spent two years in the study of medicine.

Q. Where?

A. At the Albany Medical College.

Q. After that what did you do?

A. I spent about six months in special work at Cornell, then I went to Washington in the fall of 1883.

Q. And what was chiefly your work in Washington?

A. It was the study of infectious diseases of animals in the Agricultural Department, and Professor of Bacteriology in the Medical Department of Columbian University.

Q. How long were you there, engaged in that work?

A. Until 1895.

Q. And since 1895 what have you done?

A. I have been Professor in the Harvard Medical School 11924 and Pathologist of the State Board of Health of Massachusetts.

Q. Have you done any work on the bacteriology of water?

A. Yes, I began to be interested in that question in 1886, when I made observations upon the bacteriology of the Potomac River water. That was at a time when we simply determined the total numbers of bacteria. In 1891 I was engaged for a number of months on a sanitary survey of the Hudson River between Schenectady and Albany. In view of the pollution of the river there and the prevalence of typhoid in Albany and New York. Last year I was engaged in looking over the bacteriology and the general sanitary status of the Charles River basin around Boston, with reference to the building of a fresh water basin.

Q. In connection with this work have you given the question of typhoid fever any consideration?

A. Yes, because that is the main question involved in our climate, the bearing of drinking water upon typhoid and other intestinal infections.

Q. Have you ever given particular attention to the more suitable method of determining the sanitary condition of water?

A. Yes, I think that has been the main question before us —of finding a method that would particularly estimate the relative danger of water to the public health.

11925 Q. In connection with your work with the Massachusetts Board of Health, what has been its scope?

A. The scope of the Massachusetts Board of Health is to take charge of the water supply of the whole state and its business is to examine into the relative purity of waters in the state and also to determine the best methods of sewage disposal.

Q. Have you given the subject of bacteriology any consideration and if so to what extent?

A. The subject of bacteriology as a whole?

Q. As applied to water and pathogenic bacteria?

A. Yes, I have given considerable attention to that aspect of bacteriology.

Q. What work have you done in connection with bacteriology?

A. I have published about 60 or 70 papers on the subject of bacteriology, not exclusively in relation to drinking water but in relation to diseases generally.

Q. What diseases have you considered?

A. I have studied practically all the pathogenic bacteria that are accessible, except the plague bacillus.

Q. In considering the more suitable method in determin-
11926 ing the sanitary condition of water on what have you based your opinion?

A. In considering the sanitary condition of a water I have taken it for granted that the most important indication would be the presence of fecal matter because the typhoid bacillus, the bacillus of dysentery, the bacillus of Asiatic cholera and the bacteria of all various diarrhoeal diseases, are contained in relatively large numbers in the feces, in the discharges during,

and perhaps some time after these diseases, and hence any test that would indicate the relative number of fecal bacteria would bring us as near to the exact determination of the sanitary condition of the water as we could get. In the study of the fecal bacteria there is one group of bacteria which is present not only in the human feces in large numbers but also in the feces of domestic animals, of the warm blooded animals, and this group of bacilli is very closely related to and probably a progenitor of the typhoid bacillus, and any means of revealing the relative numbers of this particular bacillus, the bacillus coli communis and its various varieties, I inferred would enable us to judge as accurately as we can without being able to actually isolate the typhoid bacillus itself. It would enable us to judge as accurately as possible of the sanitary quality of the water
11927 with reference to fecal pollution.

Q. What are the characteristics of water that in your opinion afford the most convincing evidence as to the possibility of such water being infected with typhoid bacilli?

A. In view of the fact that our methods are still unsatisfactory in the isolation of the typhoid bacillus, at least not practicable on a large scale, the colon bacillus affords us the best indication of the possible presence of the typhoid bacillus.

Q. What is the colon bacillus?

A. The colon bacillus is a bacillus which is a parasite of the mucous membrane of man and the higher mammals. It is probably adapted to live on the mucous membrane more perfectly than any of the other bacteria that we are able to handle or study.

Q. Will you differentiate between the colon bacillus and the typhoid bacillus?

A. The colon bacillus and the typhoid bacillus have so many characters in common that for years before certain tests were brought out they were confused and this can be easily traced in the medical literature of the subject. In fact, when I was at Washington I sent to one of the most prominent medical schools of the country for a specimen of the typhoid bacillus and I received a colon bacillus in return. The method I
11928 devised enabled me at once to tell the difference. For at least a good many years these two bacilli were confounded

because they were so closely allied in their biological characters. But there are certain tests that enable us to distinguish them now without any difficulty.

Q. How does the longevity of the typhoid bacillus compare with the longevity of the bacillus coli communis?

A. The typhoid bacillus is probably more perishable than the colon bacillus under a variety of conditions. The colon bacillus is a more vigorous organism than the more highly parasitic typhoid.

Q. What tests do you regard as the most useful for determining the presence and relative abundance of the coli?

A. There are a number of tests that can be applied to determine the presence; by using agar plates which enable us to determine whether certain acid-forming bacteria are present. But this method is not a final method, and we have to examine such acid-producing colonies subsequently to determine their nature, but the method which perhaps leads us more directly to the quantitative determination of bacillus coli is the fermentation test.

Q. Will you describe those tests?

A. The fermentation test is one from which we are able
11929 to distinguish the colon from the typhoid bacillus and
it is based upon the fact that the typhoid bacillus does not produce gas in culture media, such as beef broth, to which a certain quantity of dextrose has been added. The colon bacillus produces a certain amount of gas in this culture fluid in the fermentation tube, and this amount of gas consists quite invariably of a certain per cent of two gases, hydrogen and carbon dioxide. This fermentation test is perhaps the most satisfactory of those we have for determining rapidly and promptly, and within certain narrow limits of error the presence of colon bacillus in any organic fluid or any water.

Q. By whom were those tests devised and when?

A. The production of gas was determined as far back as 1885, by the discoverer of the bacillus, by Escherich, and it was in 1889 that I first came upon the idea of using the fermentation tube as a ready method of identifying certain pathogenic bacteria, and it occurred to me that the same method could be used for identifying the colon bacillus after I had found out that the colon bacillus acts like the pathogenic bacteria in the fermentation tube. That was in 1889.

Q. Have those tests devised by you been used extensively for colon determinations?

A. The fermentation test, with the fermentation tube, is
11930 used universally in this country for the recognition of
this species. It has not been used so extensively in Europe in the bacterial tests for fecal pollution because I think they are simply so far somewhat behind us in the application of these methods.

Q. Do you know whether it has been used as a test for the efficiency of filters anywhere?

A. It is used as the chief test by the Massachusetts State Board of Health in their filtration experiments.

Q. When was it that you first introduced this test, Professor?

A. I first published the method in the report of the State Board of Health for 1891, I think, of New York, and it was extensively employed by the engineer, Mr. Brown, and his assistants in 1891 and 1892 on the Hudson River for determining the relative fecal pollution of the water.

Q. Have the results of other investigators given general confirmatory evidence as to the value of this test as a criterion of the purity of water?

A. I think they have.

Q. In what instances?

A. I can not specify instances but I am under the impression that it is always used at the present time.

11931 Q. Is this in your opinion a satisfactory method for
determining the purity of a water supply?

A. It is the best that we have at the present time, and probably will not be superceded because there is no indication at present that we are any nearer to a direct determination of the typhoid bacillus than we were perhaps ten years ago.

Q. Is this method applicable to the problem of the self purification of streams?

A. It seems to me it is, if by the self-purification you mean the sanitary purification of a water for drinking purposes.

Q. Will you please explain in what way the method can be used?

A. Simply by determining the number of colon bacilli in a given quantity of water. Do you wish me to go into the technique?

Q. Yes.

A. If we take a small quantity of water, say 1 cc., and add it in fractions of 1-10 cc. to a number of fermentation tubes, say 10, and place these in a thermostat where only the colon bacillus and the related pathogenic bacteria can multiply and where the miscellaneous water bacteria are suppressed, then, if after 24 or 48 hours, in the fermentation tube, we have a certain per cent of gas, say in 5 out of 10 tubes, we can infer that
in the cubic centimeter of water added there were 5
11932 colon bacilli. The test is made more accurate by reducing the amount of water that is placed into each
tube. This, of course, must be done, when the relative pollution is very high and where the number of colon bacilli are very great, and in those instances the smaller the quantity of water used the more accurate the determination will be, because if we use a large quantity of water we may have two or three or a larger number of colon bacilli added to each tube, in which case the method fails to give quantitative results.

Q. What is the validity in your opinion in using a cubic centimeter of water and tenths, hundredths and thousandths of a cubic centimeter of water in making this test? I wish you would explain that answer in full, Professor.

A. If we had relatively pure water and should add a cubic centimeter of water to each of a number of tubes (10) and only a certain percentage of those tubes (50-60 per cent or 5 or 6 tubes) would show gas production we should infer that in the 10 cubic centimeters of water there would only be 5 or 6 colon bacilli, consequently there would not be a colon bacillus in each cubic centimeter of water. If we take a water which is much more highly polluted and we obtain a gas test with colon bacilli
in every tube our test may be inaccurate in that we may
11933 have added several colon bacilli to each tube. Then, by
taking smaller quantities of water, by taking .1 of a cc. of water for each tube, and we only have a fraction of the tubes

showing gas production, our test then becomes accurate. (If, in taking 1-10 cc. of water all our tubes still show gas production then it is necessary for us to use a still greater dilution or a smaller quantity of water in order that only a fraction of the number of tubes to which water is added show the colon bacillus.)

This is based on the old dilution method that was introduced some 20 or 25 years ago by Buchner of Munich, I think, in separating bacteria before the plate method came into use. And, it is a fairly accurate and satisfactory method of determining the number of certain classes of bacteria, as the colon bacillus, in a given quantity of water, provided we use water in sufficiently small doses so that the possible error of adding more than one bacillus to each tube is eliminated.

Q. What do you understand is meant by the bacterial self-purification of streams?

A. It consists in a reduction in the number of bacteria in a stream which reduction is not due to an increase in the lower strata of the water, that is to say, not due simply to an imperfect or perfect sedimentation, but to a complete disappearance (or destruction) of the bacteria from the water
11934 under examination.

Q. Do you know of any established principles of bacteriology and sanitary science that determine how far a stream can flow before purification is effected?

A. I do not know of any general principles that are involved, but I think each stream has certain special local conditions that need be looked into, which conditions depend on a variety of factors that vary from stream to stream, and what might be true for one stream might not necessarily be true for another.

Q. Then, each stream is an individual problem and should be considered separately and independently in arriving at a conclusion as to the self-purification from a bacterial standpoint?

A. I think each stream under consideration must be investigated by itself.

Q. Do you know of any case where the question of self-purification has been studied where the conditions as to distance and time are at all comparable with those prevailing in the Illinois River between Chicago and Grafton, a distance of 350 miles?

A. I do not recall any investigations of a similar problem extending over such a distance.

Q. Is the colon test in your opinion applicable to such a problem as that presented in the Illinois River?

11935 A. I think so.

Q. Do you know of any instance where a stream becomes practically free from colon bacilli in flowing through a country where no additional contamination from this organism occurs?

A. I believe that has been worked out by Mr. Weston in the Mississippi River, below New Orleans. I think there the colon bacillus disappears completely and no additional sewage enters.

Q. The failure to find the colon bacillus at New Orleans would lead you to what conclusion in regard to the water at New Orleans and its purification?

A. It would lead me to think that all other bacteria that are closely related to the colon bacillus, such as the typhoid and dysentery bacilli and the various modifications, the paracolon and para-typhoid had also disappeared.

Q. Will you explain in what way the life history of the colon bacillus sheds light upon the life of the typhoid bacillus?

A. The colon bacillus as stated a few moments ago is very closely related, biologically, to the typhoid bacillus, so closely that up to within a certain number of years the two were confused by many prominent bacteriologists, but with the 11936 introduction of additional tests the typhoid bacillus can now be usually recognized, but it is so closely related to the colon that its growth on the various culture media can scarcely be distinguished from that of the colon bacillus. Its growth in bouillon is very much like that of the colon. The growth of the typhoid on gelatine is very much like that of the colon bacillus. Its growth on potato is very much the same. These are the common media we use in the differentiation of bacteria. It is only when we come to certain chemical tests that the divergence begins. The typhoid bacillus does not produce indol, which means that it does not split up certain nitrogeneous substances

in the way that the colon bacillus does. The typhoid does not ferment certain sugars that the colon does, and this difference I have generally regarded as being due to a loss of function of the typhoid as it becomes more and more parasitic and this loss of function is expressed by its loss of power to ferment these sugars and to produce indol. There are thus very few differences between the typhoid and the colon bacillus, and we are justified, I think, in inferring that whatever changes the colon undergoes are undergone in nature outside of the human body also by the typhoid. Whatever degenerative changes the colon undergoes are also undergone by the typhoid. But per-
11937 haps more rapidly under certain conditions because the typhoid is more parasitic. It has probably lost certain defensive properties, that is to say as a parasite it becomes more adapted to the human body and less adapted to life outside of the human body, and that the reduced power to live will also favor the increased destruction of the typhoid bacillus in nature, a destruction which we generally assume is much more rapid than that of the more vigorous intestinal colon bacillus.

Q. Does the typhoid bacilli multiply and increase in nature that is in ordinary water?

A. It does not. Not unless we were careless and added enough culture material to give the water a temporary nutrient value which would only be so very temporarily.

Q. Will a typhoid bacillus grow in milk?

A. It will grow rapidly in milk, but before the milk becomes very acid. If other bacteria are growing in milk, the acid-acidifying bacilli for instance, then the typhoid would become promptly checked because of the increasing acidity of the milk. But generally speaking the typhoid bacillus does not increase and grow in conditions outside of the human body excepting possibly in milk under favorable conditions.

11938 Q. Do you know of any other bacteria except the colon whose life in water is more likely to furnish an index as to the life of the typhoid bacillus?

A. I know of no other group of bacilli but the colon.

Q. Have you examined the data introduced by Professor Jordan in this case relative to the abundance of the colon bacillus in the waters of the drainage canal and upper Illinois River?

A. I have.

Q. This data was colon determination for 1901, made by Professor Jordan at the laboratories at Peoria, Grafton and St. Louis and introduced in evidence in this case?

A. I have examined those figures.

Q. Are you familiar with the results obtained by him upon the colon contents of the Illinois River at its mouth and of the Mississippi and Missouri Rivers?

A. I made a particularly careful examination of his tables.

Q. What would you infer from this data assuming the method of examination to have been accurate and the results to have been reported exactly?

A. I should assume that the colon bacilli had very largely disappeared in their passage down the Illinois River and that
the colon content of the Illinois River at Grafton is
11939 therefore less than that of the Missouri and the Missis-
sippi Rivers or at least about the same. That is to say, the colon content of the Illinois at Grafton is not to any material degree superior to that of the tributaries of the Illinois River, and it is on the whole less than the colon content of the Mississippi River and the Missouri River according to these tests.

Q. Interpreting the colon determinations as to pollution, what conclusion would you draw as to the comparative pollutions of the Illinois River, the Mississippi River and the Missouri River at their mouths as indicated by these colon determinations?

A. It would seem that the condition of the water at the mouth of the Illinois River was certainly not inferior, if not superior to that of the Mississippi River and the Missouri River, at these points, as I read the testimony in these tables.

Q. On the whole from the colon determinations would you conclude that the Missouri River was more or less polluted than the Illinois or Mississippi?

MR. CORUM: I object to the question as immaterial.

A. The Missouri river is on the whole more polluted than the Illinois River. According to these figures there is not

11940 very much difference but the benefit of the doubt rests with the Illinois River without any question. Basing myself upon the colon tests as I certainly should in all such examinations I should make the table speak for itself.

Q. So far as these colon determinations go then and so far as the inference drawn from the colon contents of streams are warranted, what do those results show as to the sanitary condition of the Illinois River at its mouth as compared with the Mississippi River above Grafton and the Missouri River at Ft. Bellefontaine?

A. I should say that the Illinois River was superior in its sanitary quality to either of the other rivers, the Mississippi and Missouri.

Q. Assuming that the typhoid bacilli introduced into the drainage canal died off with the same rapidity as the colon bacilli what would you infer from the colon content of the Illinois River at Averyville and at Grafton as compared with the colon content of the various streams tributary to the Illinois?

MR. CORUM: I object to the question for the reason that the tables speak for themselves, and it is not necessary for this witness to state them.

11941 MR. TODD: In reply will state that counsel for defendant has no assurance that the Supreme Court of the United States will thoroughly understand the significance of colon determinations, and the purpose of the question is to elucidate the colon determinations for the enlightenment of the Supreme Court.

A. It seems to me that in carefully studying the colon results obtained by Professor Jordan that some of the tributaries are slightly better than the Illinois at that point and some are worse.

Q. Assuming that the typhoid bacilli were introduced into the drainage canal and that they died off with the same rapidity as the colon bacilli, what conclusion would you draw in regard to the typhoid bacillus, based upon the colon determinations at Averyville, as evidenced by Professor Jordan's tables as to their dying off?

A. According to these tables there is an enormous destruction of colon bacilli down to Averyville in the Illinois River, and basing myself upon these I should say that a similar if not greater destruction of the typhoid bacilli had taken place down to that point.

11942 Q. Do these colon determinations made by Professor Jordan taken as a whole warrant one in expressing an opinion as to the probability of the virulent typhoid bacilli passing from the sewers of Chicago to the mouth of the Illinois River at Grafton?

A. It seems to me that if virulent typhoid bacilli should actually pass from Chicago to the mouth of the Illinois River that it would be according to conditions and laws that we know nothing about, but that basing ourselves upon the close relationship of the colon to the typhoid bacillus and to this entire group of disease germs we are at present justified in saying that the virulent typhoid bacilli would be very largely destroyed at that point.

Q. Assuming that there should be no other source of contamination or infection between Chicago and Grafton except that which gets into the Illinois River from the sewers of Chicago, do these colon determinations made by Professor Jordan warrant one in expressing an opinion as to the probability of virulent typhoid fever germs passing through the sewers of Chicago to the mouth of the Illinois River? Assuming the absence of contamination as aforesaid at intermediate points?

11943 A. It would seem to me that the disappearance of the colon bacilli indicates that excluding a large amount of sewage which enters below Chicago the typhoid bacillus would probably be entirely eliminated during that long course from Chicago to the mouth of the Illinois River of three hundred and fifty odd miles.

Q. Is there any bacteriological evidence that in your opinion affords you more suitable indications than the one in question, to-wit, the colon determinations?

A. I know of none.

Q. Is there any particular method in your opinion by which it is possible to demonstrate that the typhoid bacillus actually does pass from Chicago to St. Louis?

A. There is no direct bacteriological method by which that could be done and if it were done it would be largely a matter of accident. As I say, if the typhoid bacillus were discovered it would be rather an accidental discovery because of the difficulty inherent in the isolation of the typhoid bacillus in the presence of so many other bacteria.

Q. Then, if a typhoid bacillus should be discovered in the water supply or the water of the Mississippi River at St. Louis is there any way of tracing it to the city of Chicago, assuming that other points along the rivers, the Mississippi, the Illinois and the Missouri emptied infection into those rivers?

11944 A. It would be utterly impossible to identify the source of such typhoid bacillus. The presumption would be that the typhoid bacillus would come from the nearest sewage-discharging town.

Q. Then the question as to whether the typhoid bacillus can pass from Chicago to St. Louis is one of probability only?

A. It seems to me wholly so and my opinion is based upon the index of the disappearance of the bacillus which is so closely related to it that for many years it had been mistaken for it. That is the colon bacillus.

Q. Assuming that the life of the colon bacillus in water affords the nearest approach to determining the life of the typhoid bacillus under similar conditions is it true that the colon determinations made by Professor Jordan that you have just referred to furnishes as direct evidence as can be obtained that the life of the typhoid bacillus in the Illinois River water is too brief to permit of passage down this river as far as St. Louis?

A. It seems to me that considering the enormous destruction of the colon bacillus from Chicago down to Averyville, the very great influx of sewage at Peoria, that the presump-
11945 tive evidence is very strong that the typhoid bacillus
from Chicago would not reach St. Louis because it is highly probable that the colon bacilli at the mouth of the Illinois River are probably those that have been introduced further down the stream, say at Peoria and other sewage-discharging places.

Q. What effect would polluted water have upon the life of the typhoid germ?

A. That is a very difficult question to answer categorically. It would depend upon the temperature, probably, and depend upon the amount of pollution. It is possible and probable that if the pollution is very great that these pathogenic bacilli under favorable temperature might begin to multiply for a very short period of time and in the course of this multiplication would become destroyed, because they thereby would render themselves vulnerable to destruction. That is to say it is possible that the sewage might afford enough stimulus for these pathogenic bacteria to induce them to multiply and then become destroyed. Of course if that is so, sewage would be extremely dangerous just at that time, but if we pass beyond that period it would become less dangerous because of the increased destruction of these pathogenic bacteria.

Q. Will typhoid germs live as long in pure water as in sewage polluted water?

11946 A. I have no precise data upon that subject but it would seem that some of the epidemics that have occurred in the past have been due to relatively pure water which accidentally carried the typhoid bacillus a short distance or a relatively short distance, such as the epidemics at Ithaca, New York, and at Plymouth, Pennsylvania. Such carriage, of course, is greatly favored by low temperatures, which inhibit the multiplication of bacteria, and this inhibition probably preserves the typhoid bacilli for some longer time than it would if they were attempting to multiply in the water that contained a certain amount of nutrient matter as that in polluted water. Hence, it is quite possible that sewage polluted water may under certain conditions be more destructive than pure water at certain times and within certain limits.

Q. Professor, assuming that no typhoid germs should enter the drainage canal but that the pollution from the sewers of Chicago mingled with the waters of Lake Michigan and thence emptied into the Desplaines and Illinois river would such a mixture of sewage and water add to the longevity of the typhoid germs which should enter the river at the point of Peoria, taking into consideration the chemical changes that have taken
11947 place in the water and also the amount of pollution that is added at Peoria?

A. The history of typhoid epidemics in the past has shown that the typhoid bacili can be carried by relative pure water.

Whether the polluted water is a hindrance to the destruction or favors it is a question which I think has been only recently approached experimentally by Professor Jordan and I do not feel quite competent to make any statement as to that. If I did, it would be merely in the form of an opinion.

Q. If it were true that a relation obtained between typhoid fever in Chicago and typhoid fever in St. Louis, would you not expect this relationship to be shown in an indication between typhoid rates in Chicago and in St. Louis?

A. I should think that the two curves of typhoid would be very much alike and the St. Louis curve would be slightly retarded in time.

Q. I call your attention to two charts entitled "Deaths from typhoid fever as reported in Chicago and St. Louis Official Health Reports. The deaths in St. Louis are platted one month in advance, i. e., February deaths are platted as of January, W. P. Mason," which chart was offered in evidence by Professor Mason, and shows the monthly death rate from typhoid fever for the years 1900, 1901, 1902 and 1903. Assuming that the facts from which those charts are made to be true what is your 11948 opinion as to whether or not there is any relationship or connection between the typhoid rates in Chicago and in St. Louis, as evidenced by these charts?

A. I am unable to see any direct connection between the typhoid curve of Chicago and that of St. Louis from these diagrams. The upward curve in the St. Louis charts is one which seems to correspond with the usual summer and fall increase in typhoid which is manifested throughout the civilized world, but I fail to see any direct relation between the two.

Q. Is there a rise in typhoid in the fall in other cities in this country aside from Chicago and St. Louis?

A. I think it is generally conceded that typhoid fever in our hospitals grows in August, September and October, each year. That is the time when cases are looked for.

Q. Have you examined the typhoid statistics which have been introduced in evidence in this case showing the typhoid fever upon the three watersheds of the Illinois, Mississippi and Missouri rivers, the typhoid fever conditions in St. Louis and the typhoid fever conditions in Chicago?

A. I have looked over the figures as presented to me.

Q. Knowing what you do regarding the watersheds of the
Mississippi and the Missouri rivers and the number of
11949 deaths from typhoid fever occurring in the cities draining
into those rivers would in your opinion the water of
the Mississippi River at the chain of rocks be suitable for a public water supply without filtration, supposing that the sewage of Chicago were entirely eliminated?

A. From the colon determinations of the Mississippi River at that point I should hardly consider the river water a satisfactory water for public use without previous preparation or previous filtration.

Q. Knowing the typhoid condition in the city of St. Louis. and assuming that the same was due to water supply, where would you look for the source of infection, to points as far away as the city of Chicago or to points nearer than the city of Chicago?

A. I should first look to the points nearer by all means, and if those could be eliminated then I think I should look to the city of Chicago.

Q. From a consideration of the typhoid fever upon the water shed tributary to St. Louis would it be reasonable to eliminate the points near at hand in looking for the source or cause of infection in St. Louis, assuming that it came from a water supply?

11950 A. I think it would be highly important to locate the
nearest sources first because of the vulnerability of the
typhoid bacillus in water. The further the area of infection the less the danger of the typhoid bacilli reaching the water supply. A few bacilli discharged into a stream near by would be much more dangerous than a large number discharged at a much greater distance.

Q. Are you acquainted with the experiment on the viability of a typhoid bacillus conducted in the water of the drainage canal, Lake Michigan, the Chicago River and the Illinois River by Professors Jordan, Zeit and Russell?

A. I am acquainted with them. I have heard of them.

Q. Professor, basing your knowledge upon the conditions as they exist, what is your opinion as to whether typhoid fever germs entering the drainage canal could survive the journey of 357 miles to St. Louis, assuming that the mean rate of flow is about 18 1-2 days from Chicago to St. Louis, and become a danger and a menace to the inhabitants of the city of St. Louis and the State of Missouri, taking the water of the Mississippi River in its raw state?

A. The results of Professors Jordan, Zeit and Russell have introduced a new factor into the problem in that they 11951 have defined for us, perhaps for the first time, the viability of the typhoid bacillus in polluted water. Before that time of course the results were not very definite unless we took into account the viability of the colon bacillus, but now it seems that the typhoid bacillus is fairly rapidly destroyed in polluted water, more rapidly than we have believed, and that rapidity of destruction would indicate what I suggested a moment ago, that possibly the typhoid bacillus is stimulated enough to multiply in sewage polluted water to be promptly destroyed whereas in water which contains very little organic matter its life is preserved a longer time because of a condition of latency and absence of that stimulation to multiply which I assume is very destructive to bacteria in general. If these experiments are correct, and I feel quite prepared to take the risk of accepting all of those experiments of Professors Jordan and the other gentlemen—if they are correct—then I think it would be physically impossible for the typhoid bacillus to reach St. Louis, starting at Chicago.

Q. Have you made a special study of the so-called germ tests?

A. I have for twenty years.

Q. Have you made any study of typhoid fever and ma- 11952 larial fever from the standpoint of a bacteriologist and clinician?

A. I have made very extensive studies in the agglutination tests for typhoid which is one of our newest and most reliable tests in the diagnosis of typhoid fever, and I have for a number of years studied conditions that favor malaria in the State of Massachusetts.

Q. In connection with such study as you have detailed, have you taken up the question of the proper diagnosis of the fevers, of the kinds known as typhoid and malaria?

A. We have in our state. The diagnosis for typhoid and malaria is made free by the state, at the State Laboratory, and any physician can send any specimens of blood, prepared in certain ways, for diagnosis, and we advise all physicians to use these methods of diagnosis in order to increase the accuracy of their diagnostic work.

Q. How about malaria?

A. Malaria can, as a rule, be recognized by the examination of the blood by a microscope. Now and then this is impossible, but it is usually impossible where the cases are chronic and where the patients have had repeated attacks of malaria. As a rule the diagnosis by means of the microscope is successful.

Q. Is malaria a fatal disease north of the tropics?

A. It is not so in our state. There were only two cases
11953 which I recall during my eight years of observations in
Massachusetts. There may have been others but those two I recall because I was investigating cases at the time. One was that of an old miser who lived by himself. He had been thoroughly neglected for some time and died without any medical care, and the other was the case of a girl who died in convulsions, I think, and the blood sent to me after death showed malaria parasites, although the blood examination after death is not so satisfactory as that in life. Those are the only two cases I recall in the state of Massachusetts.

Q. Are remittent, intermittent, typho-malaria, congestive and simple continued fevers distinct types of disease and so recognized by bacteriologists and clinicians?

A. It is very rare that typhoid fever and malarial fever co-exist and these cases are so rare as generally to go on record in medical publications. These terms and especially the term remittent fever figured quite extensively in medical publications about twenty years ago, but since that time it has almost wholly disappeared because of the more accurate means of diagnosis.

Q. Is it generally recognized by bacteriologists and clinicians that classifying typhoid fever in one column and intermittent, remittent and typho-malaria, congestive and simple con-

tinued fevers in another column in boards of health re-
11954 ports of cities is an improper classification from a scientific standpoint as affording a true indication of the mortality from typhoid fever and malarial fever?

A. It is at least a very indefinite form of classification because we would assume that under the terms, remittent and simple continued and typho-malarial we would have either one or the other disease, either typhoid or malaria or, a mixture of the two, which rarely occurs.

Q. Where such classifications occur showing almost an equal number of cases under the typho-malarial group with those in the typhoid column, would such a classification furnish a correct idea of the prevalence of typhoid fever in a given community?

A. I do not think that it would. The classification as you have mentioned it would indicate that the best means of diagnosis were not resorted to in determining the nature of those diseases.

ADJOURNED until 1:30 same day.

1:30 P. M., Monday, March 14, 1904.

11955 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

THEOBALD SMITH

resumed the stand for cross examination by Mr. Corum, and testified as follows:

Q. Professor, did I understand you to state that you had made an examination of the purification of the waters of the Potomac River?

A. No, not that, it was an examination of the tap water of the Potamac River through an entire year. It was one of the earliest observations made on the application of bacteriology to drinking water. It was in 1886 that that work was done. At that time I studied the variations in the bacterial life of the Potomac River water.

Q. Then you did not study the question of the purification of the stream?

A. No sir, that question did not come up excepting in this way. The relative pollution was entirely dependent upon the turbidity and it became easy to tell by looking at the 11956 water in the test tube after a little experience how many germs there were from the depth of the turbidity.

Q. Now, at what points did you make this examination in reference to the turbidity of the stream?

A. In Washington the water was drawn from one of the taps in one of my laboratories.

Q. Now, at any other points than that?

A. No.

Q. Now, what examination did you make of the water of the Hudson River?

A. The water was collected during the month of August from Schenectedav to some distance below Albany, and the water was collected according to the usual method and plated, and the bacterial count determined over this territory from day to day, and the year after that the method of the fermentation tube was extensively employed, I think it was in 1892, for the purpose of studying sedimentation and the destruction of bacteria in the Hudson River between the points mentioned.

Q. Did you investigate the purification of the Hudson River?

A. Yes. Specimens of water were collected, I think, about 18 miles below Albany, and the number of bacteria in that 11957 space of 18 miles had fallen from an average of about 10,000 to 300 or 400.

Q. You did not determine whether or not the Hudson River had purified itself at any point, did you Professor?

A. Well, that was determined to this extent that the number of bacteria dropped from an average of 10,000 per cc. to about 300 per cubic centimeter within this distance of about 18 miles, I think. I do not remember the exact number of miles.

Q. Now, was there any point where the typhoid could certainly be lacking or wanting?

A. I do not quite understand the question.

Q. Now, did you examine the waters of that river at any point where the typhoid bacillus was lacking?

A. Well, the typhoid bacillus was not looked for specifically. Simply to determine the change in the bacterial content and the object was to determine the actual sanitary or unsanitary condition of the water owing to the fact that Albany was taking the sewage polluted water and had had a high typhoid rate.

Q. Well, from your investigations could you recommend the water as being free from typhoid?

A. Well, that was not exactly the object at that time,
11958 and I should want the colon determinations of the water
18 miles below Albany before I could venture to say that it was safe for drinking water.

Q. Now, you stated that the purification of streams was local and depended upon each particular stream?

A. That the conditions under which the purification takes place would vary more or less from stream to stream.

Q. Now, have you made any examination of the waters of the Illinois River?

A. None personally.

Q. I understand you made no examination of the waters either before or since the opening of the drainage canal?

A. None.

Q. You spoke this morning of the fermentation test. Is not that test frequently rendered inaccurate by the more rapid multiplication in the tube of other saprophytic forms, such as the streptococci?

A. No. The advantages result, from the fact that the colon bacillus is an organism that multiplies very rapidly at high-temperature and when these tubes are inoculated they are put at once into an incubator and that suppresses the bulk of the water bacteria, so that the test is not injured by the presence of
these water bacteria, but if there are a large number of
11959 colon bacilli it becomes necessary to use minute quanti-
ties of water as I mentioned this morning, as Professor Jordan has done in using quantities as low as .001 cc.

Q. The colon bacilli were found at New Orleans when large amounts of water were examined?

A. Can you tell me what amount was examined?

The Commissioner: He asked you the question.

The Witness. Was the colon bacillus found?

Mr. Corum: Yes.

A. I understand it was not found even with the use of a large amount of water, although I am prepared to be corrected on that point by printed evidence.

Q. Professor, you spoke in the direct examination of the complete removal of the colon bacillus at New Orleans. When you consider the enormous dilution at this point do you not think that it was this factor rather than any other that made its detection impossible?

A. The difficulty of finding the colon bacillus in 300 cc. of water practically means the same thing as purification from a sanitary point of view. That number of colon bacilli means an exceedingly small percentage of colon bacilli as compared with other pure spring and surface waters, and whether the water had been diluted or whether the river had been
11960 purified the result practically is the same.

Q. I understand in your opinion the typhoid germ does not increase in ordinary water?

A. It does not, I should say.

Q. But in water containing nutritive matter as sewage it does increase in short periods does it not?

A. If the temperature is high enough. The temperature must be at least probably 70 degrees Fahrenheit, and the nutrient matter must not be mixed with poisonous substances, like factory waste or acids or other injurious agents, then a slight multiplication might take place.

Q. Do you not find typhoid bacilli in water that is grossly polluted?

A. Typhoid bacilli have been repeatedly found in the intestinal tract of human beings and I think in three or four instances it has been found in water which was suspected of conveying typhoid. I think these instances occurred in Germany where the discovery of the typhoid fever bacillus was made by a bacteriologist so competent that we can not doubt his authority.

Q. Have you made any examination as to the amount of sewage that is emptied into the Illinois River at Peoria?

A. None further than to read the records of the bacterial
11961 count as made by Professor Jordan for 1900 and 1901.

Q. And from that source of information I believe you stated that you would be of the opinion that much of the typhoid germs if found at the chain of rocks in the city of St. Louis came from Peoria and other cities instead of Chicago?

A. Rather than farther up.

Q. Now, assuming that the sewage of Peoria was infected with these germs and that the Chicago drainage canal being turned into the Illinois River would not the fact that this canal was made a tributary to the Illinois River, hasten the flow from Peoria to St. Louis?

A. Do you mean increase the velocity?

A. Yes?

Mr. Todd: I object to the question on the ground that it is not proper cross examination as it embraces the question of engineering and hydraulics, a subject not touched upon by this witness who has not qualified as to knowing the facts in regard to the hydraulic condition that obtained along the Illinois River.

A. Of course it is impossible for me to say to what extent the current would be increased from Peoria down on account of such increase of the volume from above. This increase 11962 in volume might be caused by any freshet or any increase in the rainfall.

Q. It might also be due to the flowing of the waters of any tributary of the Illinois River into the river would it not?

A. It might be. The current might be increased by any increase in volume.

Q. Then it follows as a logical sequence that it would carry the typhoid from Peoria down to St. Louis in a shorter space of time does it not?

A. It does logically. It also follows there would be a great deal more dilution of the Peoria sewage.

Q. Now, Professor, based on the knowledge which you have with reference to this subject are you prepared to state that the coli bacilli are not present at Grafton?

A. I am not prepared to state that because it is given here in the table that it is present at Grafton and we should expect the colon bacilli to be present in almost any surface water. It depends upon the number of colon bacilli per unit of volume upon which our judgment of the sanitary quality of a water is based.

Q. Your table also shows that it is present at the city of St. Louis does it not?

A. It does.

Q. Have you anything in the table or any other source of information that indicates the source from which this
11963 colon bacillus emanates?

A. The original source?

Q. Yes.

A. It would be of course difficult to distinguish a colon bacillus that came from the intestinal tract of higher animals from the colon bacillus that came from the intestinal tract of man, but so far as we know the colon bacillus is essentially a parasite of the intestinal tract of man and higher mammals and that the colon bacillus responding to the temperature test does come from fecal contamination, either directly or through the survival of a certain number of days in a water.

Q. But you are not prepared to state here that this colon bacillus emanates from the sewage of Chicago or some other intermediate point between here and St. Louis?

A. The colon bacilli discovered at St. Louis?

Q. Yes?

A. The evidence upon which I am basing my statement, and I think it is perfectly reliable, shows that the colon bacilli largely disappear at Averyville or before they reach this second source of contamination,—the group of towns at Peoria,—consequently it would be inferred that the colon bacilli which are at St. Louis are largely recruited from the places further down and that the colon bacilli which have almost disappeared
11964 at Averyville would have completely disapeared at the mouth of the Illinois River.

Mr. Todd: I do not care to ask any questions on re-direct examination.

THEOBALD SMITH.

11965
VICTOR C. VAUGHAN

a witness called on behalf of the defendants, after being duly sworn by the Commissioner, testified as folows:

Direct Examination

By Mr. Todd:

Q. What is your name?

A. Victor C. Vaughan.

Q. What is your business?

A. I am a physician and a teacher.

Q. Where do you live?

A. I live at Ann Arbor, Michigan.

Q. What institution of learning?

A. I am connected with the University of Michigan.

Q. From what institute did you graduate?

A. The University of Michigan.

Q. When did you graduate there?

A. I took a Master's degree there in 1875, Doctor of Philosophy in 1876 and Doctor of Medicine in 1878.

Q. After graduating from the University of Michigan in 1878, in medicine, what did you do?

A. I taught in the University of Michigan and practiced 11966 medicine. I have also studied abroad to some extent.

Q. What institutions abroad have you attended?

A. I studied with Robert Koch in the University of Berlin.

Q. How long were you there?

A. Well, I have been there two or three times. The longest time I was there was for about three months in 1888.

Q. Have you been connected with the University of Michigan ever since?

A. I have been teaching in the University of Michigan since 1876.

Q. What branch of science do you teach?

A. I teach hygiene and physiological chemistry.

Q. Have you made a study of the so called germ diseases?

A. I have. As a teacher of hygiene it would be necessary for me to study the germ diseases.

Q. Have you had anything to do with the study of those diseases outside of the institution at Ann Arbor?

A. Yes, I have been a member of the Michigan State Board of Health. I am serving my third term now as a member of that board. I have been called upon frequently to examine into epidemics in the state and I served on the Government Commission and am still serving on the United States Government 11967 Commission for the study of typhoid fever.

Q. When did you begin your service for the United States Government?

A. I was enlisted in the Army June 9, 1898, and I think the Special Commission appointed to study typhoid fever was some time in August, 1898.

Q. Will you relate your experience in connection with the study of typhoid fever as it related to the army?

A. In August, 1898, after my return from Santiago, there was a commission appointed to investigate the causes and spread of typhoid fever in the camps of the United States. This commission consisted of the late Major Walter Reed, the late Major Shakespearre and myself, and we inspected the camps.

Q. Name them, Professor?

A. We went to camps Alger, Fernandino, Jacksonville, Huntsville, Alabama, Chickamagua, Georgia; Knoxville, Tenn.; Camp Meade, Pennsylvania, and the other members of the Commission went to Montauk. I did not. I was sick at the time. Those were the ones I went to.

Q. How many cases of typhoid fever came under your observation during this experience in the army?

A. Well, it would be hard to say. I think I must have 11968 seen several thousand cases of typhoid fever, four or five thousand probably.

Q. Have you had any other experience with typhoid fever besides that which you have related?

A. As a member of the commission I have been engaged practically ever since that time in writing up the statistics and studying the spread of typhoid fever and I have also been called upon frequently to investigate outbreaks of typhoid fever in different parts of the country, in Michigan and other states as well.

Q. Have you made a special study of the so-called germ diseases?

A. I have.

Q. Do these diseases caused by germs come within the scope of your study?

A. Yes sir.

Q. Have you made any special study upon typhoid fever or malarial fever from the standpoint of a bacteriologist and a clinician?

A. I have.

Q. In connection with such study as you have detailed have you taken up the question of the proper diagnosis of fevers, of the kind known as typhoid and malarial?

11969 A. I have.

Q. How extensively, Doctor?

A. Our Commission had charge of all the diagnoses that were made in the army camps after the appointment of the commission, that is we selected the men and put them to work and overlooked their work in the various camps in the United States.

Q. Have you had any experience in the diagnoses of these fevers either in the laboratory or at the bed side?

A. I have had experience both in the laboratory and at the bed side.

Q. What is typhoid fever and its clinical diagnosis?

A. Typhoid fever is an acute septecimia, due to infection with a specific germ known as bacillus typhosus.

Q. What is malarial fever and its clinical diagnosis?

A. Malarial fever is a disease due to infection with a malarial parasite of which there are at least three well known varieties.

Q. What is intermittent, remittent, typho-malarial, congestive and simple continued fever and their clinical diagnosis?

A. Most of the cases diagnosed under those different heads are forms of typhoid fever. Malaria is sometimes called remittent fever but the majority of the cases in this country
11970 that are diagnosed under those heads, especially in the
northern parts of the United States are really cases of typhoid fever.

Q. Are remittent, intermittent, typho-malaria, congestive and simple continued fevers distinct types of disease and so recognized by bacteriologists and clinicians?

A. They are not.

Q. What significance do you attach to those terms as applied to fever when they appear in vital statistics?

A. They almost invariably—there are some exceptions, but almost invariably they mean typhoid fever.

Q. Assuming that the number of deaths reported as occurring from typhoid fever in the city of St. Louis as evidenced by the annual report of the board of health of the city of St. Louis, Health Department, are as follows:

	1890	140
	1891	165
	1892	441
	1893	215
	1894	171
	1895	107
	1896	106
	1897	125
11971	1898	95
	1899	131
	1900	168
	1901	193
	1902	222
	1903	288

What is your opinion, based upon your knowledge of the different kinds of fever as to whether these reported deaths from typhoid fever in the city of St. Louis health reports correctly state the true typhoid conditions existing in the city of St. Louis for the years mentioned?

A. I dare say there were more deaths from typhoid fever than are reported here.

Q. Assuming further that the number of deaths reported in the same reports under the heading remittent, intermittent, typho-malarial, congestive and simple continued fevers is as follows:

1890	226
1891	296
1892	326
1893	284
1894	179

11972	1895	155
	1896	177
	1897	172
	1898	134
	1899	148
	1900	112
	1901	80
	1902	102
	1903	91

Do the number of deaths reported as occurring from the typhoid fever alone in the city of St. Louis properly represent in your opinion the total number of typhoid deaths actually occurring in the city for the period in question?

A. They do not.

Q. What reasons have you for stating that they do not?

A. My experience shows me that malaria is not a common disease in Missouri or in that section of the country. The disease itself is rare and death from the disease is exceedingly rare, so rare that practically it does not occur. You may ask me what I base that statement on. Missouri sent six regiments to the war in 1898. I have studied the records of all of these regiments and although in some of them many cases were 11973 diagnosed by the surgeon as malaria, more careful examination was instituted by our board showing that these were not malarial cases but they were cases of typhoid fever. One of these regiments remained, if I remember correctly—I can tell positively by looking at the records in Jefferson Barracks, practically a part of St. Louis, until July, 1898. While malaria was frequently reported by the medical officers in charge of these regiments, more careful examination showed that they were cases of typhoid fever. For instance the Sixth Missouri developed 286 cases of typhoid fever and had 19 deaths from typhoid fever. The sixth Missouri was stationed at Jefferson Barracks until early in August. I have not the exact date. It then went to Jacksonville, Florida, and there our board inspected the Sixth Missouri and studied the cases clinically, and bacteriologically. They were cases of typhoid fever and not cases of malaria.

Q. How many cases of malaria were recorded?

A. I can not tell you exactly now.

Q. That turned out to be typhoid?

A. I can not tell you from that regiment but I can tell you from some other regiment.

Q. I wish you would?

11974 A. Well, of 83 cases of so called malaria from the Fifth Maryland that were sent to the hospitals in Baltimore, 80 cases proved to be typhoid fever. I think that is just about right. It was about that per cent. I have not the figures exactly here. That is substantially correct.

Q. To what do you attribute the failure of these statistics assumed in the foregoing hypothetical question to properly disclose the number of typhoid fever deaths occurring in the city of St. Louis?

A. For the reasons just given that malaria is certainly a very rare disease in Missouri and death from malaria is much rarer, in this section of the United States.

Q. You are acquainted with the conditions in St. Louis are you not?

A. Very slightly. I can not say that I know very much about the local conditions existing in the city of St. Louis.

Q. In the State of Missouri?

A. Somewhat. I was born and reared in Missouri. I know something about it. I go back there nearly every year. I know something about the conditions existing in Missouri.

Q. Why is it that the doctors employ the terms, remittent, intermittent, typho-malaria, congestive and simple continued fevers to fevers that are recognized as being either typhoid or malaria? 11975

A. There are many reasons why doctors do this. In the first place typhoid fever in its earliest stages is often a remittent disease, that is it is a disease where fever exists for a few hours and then there is no fever. In its earliest stages it is a remittent disease. That is one reason why it is done. The second reason why it is done is that doctors really think they are dealing with malaria when they have typhoid fever, and I have no doubt the third reason that actuates doctors in using these terms is that they are less likely to frighten the patient and friends of the patients. It does not seem quite so dreadful a thing to have malarial fever as to have typhoid fever, and the fourth reason is that the means of accurately distinguishing between malarial and typhoid fever have been discovered only within recent years, and even now are not always in the hands of practicing physicians. These, I think, in sum and substance are the reasons why doctors so frequently use these terms remittent, intermittent, typho-malarial, congestive and simple continued fevers when actually they have typhoid fever to deal with.

Q. Do you know of any city in the country where the death rate from malarial fever alone is as high as in the city
11976 of St. Louis, as evidenced by the number of deaths as assumed in the hypothetical question under the heading intermittent, remittent, typho-malaria, congestive and simple continued fevers, occurring in the health reports of the Board of Health of the city of St. Louis?

A. I am sure there is no city in the United States where there are so many deaths from malaria fever as there reported. Of course there may be cities where the deaths reported are equal to those in St. Louis, but there are no cities where there are that many malarial deaths.

Q. What proportionate deaths in the column under the heading, remittent, intermittent, typho-malaria, congestive and simple continued fevers assumed in the foregoing hypothetical question as occurring in the city of St. Louis as evidenced by the report of the Board of Health in your opinion should be classed as typhoid?

A. I think 100 per cent. of them should be so reported. Now, of course, there may be a few of them that were not typhoid fever; they may have been something else.

Q. What proportion as malarial fever?

A. None.

Q. What do the mortality statistics of malaria show in
11977 cities where careful attention has been paid to malarial fevers in regard to the number of deaths occurring from malarial fever?

A. Well, there are practically no deaths from malaria in this country unless it is in New Orleans or some other extremely southern city. Of course, there may be two or three in a year in a large city. In Albany 5 cases were reported in the last year from malaria, but it is very doubtful that those were really malaria.

Q. Is it generally recognized by bacteriologists and clinicians that classifying typhoid fever in one column and intermittent, remittent, typho-malarial, congestive and simple continued fevers in another column in board of health reports of cities is an improper classification from a scientific standpoint as affording a true indication of the mortality from typhoid fever and malaria?

A. It certainly is.

Q. Assuming that the reports of the board of health of the city of St. Louis by the month from 1895 to 1903, inclusive, under the heading typhoid fever, which for the purpose of convenience is designated "A" in the table that follows and as remittent, intermittent, typho-malaria, congestive and simple continued fevers, for the sake of convenience designated as "B" in the table as follows, which table, prepared and sworn to by Professor Jordan, based upon said reports, is as fololws:

11978

ST. LOUIS.

	1895		1896		1897		1898		1899	
	A.	B.	A.	B.	A.	B.	A.	B.	A.	B.

Dec.	19	7	20	3	25	6	31	5

A—Typhoid fever.

B—Remittent, Intermittent, typho-malarial, congestive and simple continued fever.

11980 Will you please state what construction you place upon this table as showing the relative mortality from typhoid fever and malarial fever in the city of St. Louis during the period covered by the foregoing table?

A. I think the total deaths there as reported from all of these cases more accurately give the number of deaths from typhoid fever.

Q. From a careful consideration of the tables which have just been assumed in the hypothetical question, what conclusion would you draw as to whether the outbreaks of typhoid fever in the city of St. Louis were of an epidemic during this period or the normal death rate due to local causes or otherwise?

A. Well, without knowing anything about the local conditions in St. Louis, simply as a student of epidemiology, and looking at the distribution of these diseases according to months I should say that the probabilities are that typhoid fever in St. Louis, with the possible exception of the year, 1892, was due to local causes rather than to any infection of the general water

supply. When there is an infection of the general water supply as a rule the outbreak of typhoid fever is explosive in character, that is there are a great number of cases which occur within a short time. They are not distributed along so evenly
11981 through the months. That is the rule. Of course there may be possible exceptions as to this. I do not know about the local conditions but when there are positive infections, (certain infections of the water supply) the outbreak of typhoid fever is of an explosive character as happened at Grand Forks, North Dakota, some years ago; Duluth, Minn., at Butler, Pennsylvania, recently; Plymouth, Pennsylvania, some years ago; Ithaca, New York, recently, and as now occurring at Watertown, New York. That is the general rule of epidemics due to the infection of the water supply.

Q. Assume that on April 1, 1895, the total number of wells in the city of St. Louis was 4846, and assume that in pursuance to an order of the board of health of the city of St. Louis, directing an examination of these wells, that the City Chemist, after an examination of 59 of these wells condemned them as being unsanitary, and assuming further that in August, 1895, upon a report of the city chemist condemning 7 more of the wells, the board of health of the city of St. Louis passed a resolution to the effect that the city chemist should make no further examination of the wells in question, and that since 1895 none of these wells have been condemned. What effect would the pres-
11982 ence of such wells of known pollution have in affecting the typhoid condition in a city such as St. Louis?

A. As I stated a moment ago these figures as given here showing the distribution of typhoid fever render it highly probable that the local conditions, such as infected or polluted wells indicated the distribution of typhoid fever by contact were the causes of the spread of typhoid fever in St. Louis rather than the infection of the general water supply. I should answer your question then specifically by saying polluted wells, if they were specifically polluted with typhoid fever, the use of the water from such wells, would undoubtedly cause typhoid fever.

Q. Assume that the added totals of tables from typhoid fever and the tables from remittent, intermittent, typho-malaria, congestive and simple continued fever, as they appear in the reports of the board of health for the city of St. Louis are as follows:

1890	361
1891	381
1892	767
1893	499
1894	350
1895	262
11983 1896	283
1897	297
1898	229
1899	279
1900	280
1901	278
1902	224
1903	379

What do those tables as above indicated represent in your opinion as the mortality condition of typhoid fever in the city of St. Louis covering the period as above indicated, after allowing the said remittent, intermittent, typho-malaria, congestive and simple continued fever column such proportion as being typhoid fever as in your opinion you should allow. What is your opinion as based upon the statistics as assumed in the foregoing hypothetical question as to typhoid deaths under the remittent, intermittent, typho-malaria, congestive and simple continued fevers tables in the city of St. Louis as to whether said statistics show an increase or a decrease in the typhoid fever mortality in the city of St. Louis since 1899?

A. If you take the years from 1890 to 1899, inclusive, you have total deaths of 3708 for ten years. That would given an average death rate of 370. If you take the four years since
11984 1899 it would give you 1261 deaths or an average of 315
deaths so there would be if you included all the years from 1892 to 1903, inclusive, then the average would be greater before 1900 than since 1900. If you cut out the years 1892 and 1893 it would be smaller.

Q. Assume that two circular letters one issued in the fall of 1900, and another issued in the fall of 1901, were issued by the health commissioner of St. Louis calling the attention of physicians to the fact that the law required them to report all cases of typhoid fever and all deaths of typhoid, and at that time that letter was sent out, the question of opening the drainage canal was being agitated in the public press of St. Louis, and there was considerable discussion and an investigation was going on at that time of the analysis of the samples of water collected, etc., and was attracting considerable attention. From your examination of the statistics of St. Louis, as heretofore assumed in the hypothetical questions, heretofore asked you, for the years 1900, 1901, 1902, as compared with previous years, does the effect of such a letter, assuming that the same has been sent out to the doctors by the health department of St. Louis manifest itself in those statistics?

11985 A. It probably does. I should assume that the object in sending out such a letter was to get a more perfect report of deaths from typhoid fever and I should judge from the decrease you see here in the deaths from malaria that such object was accomplished.

Q. In what way does the effect of such a letter appear from the statistics?

A. By an increase in the number of deaths reported from typhoid fever.

Q. Is there any proportionate loss from the typhoid malarial column manifested in the statistics?

A. I believe there is, yes sir. While in 1901 there were only 80 cases, the smallest number in any one year, from and including 1900. In fact all three years, 1901, 1902 and 1903, the number of deaths reported as being due to malaria is less than any year preceding that.

Q. From your examination of the typhoid and typho-malarial deaths as assumed in the foregoing hypothetical question, what is your opinion as to whether these two tables taken separately correctly show the typhoid condition of the city of St. Louis for the period mentioned?

A. The two tables taken separately do not correctly show the death rate.

Q. Upon what do you base your opinion that they do not
11986 correctly show the typhoid condition in St. Louis, taking them separately?

A. My opinion is based upon the fact which is well known to most physicians and certainly I have special reasons for knowing it, that malaria is not a frequent disease in this country and is certainly a very rare cause of death.

Q. From your knowledge of these classes of fevers mentioned in the two columns of vital statistics as heretofore assumed, how should they be treated by a bacteriologist, statistician and clinician in order to arrive at the typhoid fever mortality in the city of St. Louis?

A. They should be combined, that is the two tables should.

Q. Have you made any study of comparisons between the typhoid and typho-malarial groups of the city of St. Louis with those of any other city?

A. I have made some studies of the comparison between typhoid fever in St. Louis and typhoid fever in other cities. I have here the number of cases reported and the number of deaths in each year from 1896 to 1902, inclusive, for New York City, Minneapolis, Philadelphia, Richmond, Buffalo, Albany and
Cleveland, and it is rather interesting to note that the
11987 death rate in Buffalo has increased quite markedly since
1899.

Q. That is the year of the opening of the canal is it not?

A. I believe so. Shall I give you the figures.

Q. I wish you would?

A. In 1896 there were 274 cases in Buffalo, reported, with 68 deaths.

In 1897	201	cases	reported,	63 deaths.
In 1898	280	"	"	98 deaths,
In 1899	212	"	"	88 deaths,
In 1900	322	"	"	90 deaths,
In 1901	405	"	"	98 deaths,
In 1902	385	"	"	125 deaths.

Of course in New York there has been a big increase in typhoid fever. I imagine, however, that is due to the enlarging of the city rather than to any other cause, but the cases there jump from 1950 in 1899 to 2658 in 1900, and in 1902 getting up to 3871.

In Minneapolis there has been an increase, if we exclude the year 1897, when there was an epidemic of typhoid fever in Minneapolis.

11988 Q. What has been the general tendency in regard to typhoid fever during the last five years?

A. Do you mean so far as its location is concerned?

Q. As to increase or decrease?

A. I have an idea and I think most epidemiologists have an idea that typhoid fever has been more widely disseminated over the country and there are more cases and more deaths from typhoid fever. I do not mean that the per cent of deaths has increased, but the number of cases has increased and consequently the number of deaths has increased, and I dare say that this is in part due to the distribution of typhoid fever from the camps in 1898. That is probable.

Q. Does St. Louis occupy a different position in regard to this increase in your opinion than the other cities you have referred to?

A. No, there are other cities which show some increase. Of course I might have picked out cities that showed marked increase, but these are cities which I had already looked up in making my Government report and I simply took them as I had them.

Q. Assuming that the following table testified to in evidence by Professor Jordan, as compiled from the typhoid 11989 fever mortality and the remittent, intermittent, typho-malaria, congestive and simple continued fever mortality of the health report of the city of St. Louis and based upon the population of the city of St. Louis for the years 1890 and 1900 acording to the United States Census reports and the intervening year by Farr's Formula, which table is as follows:

11990 TYPHOID FEVER DEATH RATES.

ST. LOUIS.

Death Rate per 100,000.

Year.	Population.	Typhoid fever alone.	Typhoid fever plus 50 per ct. of deaths recorded under heading of intermittent fever, etc.	Typhoid fever plus all the deaths recorded under the heading intermittent fever, etc.
1890	451,709	30.0	56.67	81.2
1891	462,763	35.6	56.98	82.3
1892	474,077	93.0	127.40	161.7
1893	485,668	44.2	73.52	102.7
1894	497,565	34.3	52.24	70.3
1895	509,740	29.9	30.35	51.3
1896	522,225	20.2	37.37	54.1
1897	533,762	23.4	39.53	55.6
1898	548,590	17.3	29.53	41.7
1899	361,510	23.3	36.49	49.6
1900	575,238	29.2	39.07	48.6
1901	589,315	33.5	40.39	47.1
1902	603,736	36.7	45.21	53.6
1903	618,510	46.5	54.0	61.3

Will you please state what in your opinion, based upon
11991 the tables heretofore read, as to whether typhoid fever has
increased or decreased in the city of St. Louis since 1900,
over the conditions that obtained in St. Louis prior to 1900,
and state your reasons for your answer?

A. Well, there certainly has been some increase, unless we go back to the epidemic years of course, and take in 1890 and 1891. Typhoid fever, if we take that alone, then there has been an increase, if we leave out 1892 and 1893. With the exception that in the year 1898 there was a drop, I believe. There was also a drop in 1896 compared with 1895 and a drop in 1895 compared with 1894.

Q. Is there such an increase as you observed as would be characterized as an epidemic?

A. No. An epidemic of typhoid fever, and especially a water epidemic of typhoid fever is where the increase in typhoid fever amounts up to 100 per cent. or more, and even 200, 300 or 400 per cent.

Q. What is the character and nature of the increase that you observed from a study of these statistics?

A. On the whole a gradual increase such as you might ex-
11992 pect would be due to local conditions, especially if wells
were getting more and more filthy and were not condemned.

Q. Have you seen the charts offered in evidence by Professor Mason, which charts have the caption "Deaths from typhoid fever as reported in Chicago and St. Louis, by said health reports. Deaths in St. Louis are platted one month in advance, i. e., February deaths are platted as of January, W. P. Mason." That is where the typhoid deaths of St. Louis and of Chicago are platted by the month?

A. Yes, I have seen those charts. I saw them this morning.

Q. From a study of the typhoid conditions as assumed in the hypothetical questions put to you in regard to St. Louis and the conditions in Chicago as evidenced by these charts, what is your opinion as to whether or not the typhoid conditions in St. Louis bear any relationship to or are consequent of the typhoid conditions that exist in Chicago for the last four years?

A. These charts certainly would indicate that there is no casual relation between typhoid fever in Chicago and typhoid fever in St. Louis because if there was the charts should have the same general curve, charting the typhoid fever in St. Louis
one month later than the typhoid fever in Chicago and
11993 such a relation is not shown by these charts.

Q. If from a consideration of the typhoid conditions as they exist in St. Louis, as evidenced by the typhoid statistics assumed, both the typho-malarial and typhoid death columns you were called upon to attribute a cause for that typhoid condition where would you look for the cause?

A. I should look for the cause certainly in St. Louis in the local conditions. It is generally assumed that typhoid fever is carried altogether by means of drinking water. This is wholly an erroneous assumption. I have some charts here which illustrate that if you care to have me exhibit them. Here is a chart of a regiment, which happens to be the 15th Minnesota, as they were in camp upon the fair grounds at St. Paul, and at Fort Snelling. These men were drinking the same water exactly and still some companies remained practically free from typhoid fever while other companies were largely affected. Typhoid fever if it once starts often spreads by contact from person to person, infection of houses, clothing, bedding, etc. Especially is this likely to be the case in crowded parts of cities and it is certainly true or was true among our troops. Typhoid fever was spread largely by what we call tent or comrade infection.

Q. Does the typhoid fever condition in St. Louis since
11994 January, 1900, as assumed in the tables differ from the
typhoid conditions in other cities in the country for that same period?

A. Certainly not from some other cities. Of course there are certain cities in which there has been a decrease in typhoid fever and other cities in which there has been an increase and in some of these a much more marked increase than in St. Louis.

Q. Would you associate the increase of typhoid fever in St. Louis during the last four years, such as you have indicated it to be, based upon statistics as assumed with the opening of the drainage canal in January, 1900?

A. I think that there is no evidence so far as I can see from these figures that the drainage canal has had anything to do with the typhoid fever in St. Louis for the following reasons:

In the first place, as I have already stated, the distribution of typhoid fever in St. Louis as shown in these tables, is indicative of local contamination and spreading by contact rather than of any general water infection.

In the second place there are certain cities in the list that I have given here where the increase in typhoid fever has been more marked than in St. Louis, and in these cases notably that of Buffalo, the drainage of Chicago has been turned away from Buffalo rather than to it.

I think that there has been a gradual increase of typhoid
11995 fever throughout the country for the last few years, and
the increase in St. Louis has been gradual. It has been slow and I do not think that there is any evidence from the figures that there has been any great contamination of the water

supply of St. Louis. There has been no explosive outbreak of typhoid fever there.

Q. Do you know of any instances where typhoid fever has been spread by contact? If so, please give the instances.

A. I have already shown the table illustrating the spread of typhoid fever in the Fifteenth Minnesota where it was spread by contact. There are still more striking illustrations, probably. In 1898 the Seventh army corp was stationed at Jacksonville, Florida. An army corps in round numbers is 30,000 men. The number of deaths from typhoid fever in the Seventh Army corps was 421. Now, this army corps was at Jacksonville only during the summer. Some regiments a shorter time and some a longer time, some nearly three months and some only a few weeks. The population at Jacksonville at that time was in round numbers 30,000. The soldiers and the people at Jacksonville drank
the same water from the same artesian well. There were
11996 during the whole year of 1898 nine deaths from typhoid
fever if we take those reported as only typhoid fever. If we take all those that were reported as due to typhoid fever, remittent, malaria, typho-malaria and intermittent fevers, the total number of deaths among the people of Jacksonville was 21. In other words there were 400 more deaths from typhoid fever among the 30,000 soldiers there and they were there for only about three months, than there was for the whole year among the 30,000 people of Jacksonville and all drinking the same water. This illustrates that typhoid fever is often spread by other means than by drinking water. There was one division encamped at Knoxville, and we spent some time investigating the conditions at Knoxville, but we could find no case of typhoid fever in Knoxville. There might have been a case but we went with the health officer and tried to find a case of typhoid fever among the cititzens of Knoxville at that time but we were not able to do so. At the same time there were many hundreds of cases among the soldiers and they were drinking the same water.

11997 CROSS-EXAMINATION by Mr. Corum.

Q. But the fact remains, does it not, Professor, that typhoid fever may be scattered or contracted from the use of polluted drinking water?

A. Certainly that is true. That is one way in which it is spread.

Q. Where did you obtain the statistics purporting to show the typhoid death rate in the cities mentioned by you, to-wit: in the city of New York, the city of Buffalo and the city of Minneapolis?

A. I obtained them from the health officers of those cities.

Q. Did you get them directly from the health officers?

A. I did and the original papers were signed by the health officers.

Q. You are not acquainted, I believe you stated, with the local conditions existing in St. Louis?

A. No sir, except as an occasional visitor to St. Louis.

Q. How recently have you been there?

A. I was there a little over a year ago.

Q. At that time did you make any investigation as to the local situation?

11998 A. No sir, of course I know something about it by hearsay.

Q. Assume it to be a fact that the St. Louis intake was removed to its present location in 1895 because local pollution traced to it had passed the old location, would it not be a fair test to compare the conditions in St. Louis between the years 1895 and 1903 rather than between the years 1890 and 1903?

A. Why, yes, I think so.

RE-DIRECT EXAMINATION by Mr. TODD.

Q. You have instituted a comparison for the five years or four years previous and the four years after have you not, in giving your answers to my questions?

A. I have, yes sir. I have omitted the epidemic years.

VICTOR C. VAUGHAN.

ADJOURNED until 10:00 a. m., Tuesday, March 15, 1904.

11999 10:00 a. m., Tuesday, March 15, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and C. D. Corum, Esq., representing complainant; James Todd, Esq., representing the defendants.

EBEN J. WARD,

a witness on behalf of the defendants, being duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Mr. Todd:

Q. What is your name?

A. Eben J. Ward.

Q. What is your business?

A. Civil Engineer.

Q. How long have you been a civil engineer?

A. Since 1880.

Q. Are you a graduate of any technical institution?

A. I took my second degree at Sheffield Scientific School at Yale, in 1880.

Q. Since then what have you done?

A. Been practicing my profession most of the time.

12000 Q. Have you ever made a survey of the Illinois River for the purpose of ascertaining the number of acres that were inundated on the bottoms of the Illinois River?

A. I made a cognizance in 1890 and again in 1892.

Q. Between what points did you make this survey?

A. In 1890 between Lake Joliet and the mouth of the Illinois River and in 1892 between Lake Joliet and the La Grange dam.

Q. Did you figure out the number of acres that were overflowed or subject to overflow between those points in the Illinois valley?

A. Yes sir, for each of those years I estimated that.

Q. Will you please state what your surveys showed as to the number of acres of land subject to overflow between Lake Joliet and the mouth of the river for 1890?

A. The flood of 1890 was what we would call an upper river flood. By that I mean that as far as Peoria the low lands were considerably inundated but from Peoria down the water was confined almost entirely to the channel proper of the river, and slight rises along the bayous and inlets. That was in 1890. That was the condition in 1890.

12001 Q. How did 1892 differ?

A. In 1892 there was a general overflow throughout the entire Illinois River, that is the river below Peoria, it overflowed practically from bluff to bluff. In 1890, below Peoria, the water was confined to the channel proper of the river, but in 1892 it overflowed from bluff to bluff, clear to the mouth of the river.

Q. Will you state the number of acres along the Illinois River valley that is subject to overflow?

A. From the eastern line of Grundy county to the La Grange dam, my estimate for 1892 is 200,000 acres. Now, below the La Grange dam in 1892 the water overflowed from bluff to bluff. I followed the overflow line below the La Grange dam clear to the mouth of the Illinois River, therefore I know it overflowed from bluff to bluff. The drift wood was all the way down there and to come at an estimate or a guess, I would estimate that below there, there was as much more overflowed, probably 200,000 acres below there, although I did not trace the water line on the map below the La Grange dam for 1892. Therefore, there are times when that river overflowed from bluff to bluff below the La Grange dam.

12002 Q. How many acres would you estimate the amount of lands subject to overflow along the Illinois valley from Lake Joliet to the mouth of the river?

A. In the neighborhood of abot 400,000 acres.

CROSS-EXAMINATION, by Mr. Corum.

Q. Did you make a survey of this water in 1890?

A. I made a recognizance of it, one form of a survey.

Q. How many acres at that time according to your estimate?

A. From the eastern line of Grundy county to the mouth of the Illinois River, 150,000 acres.

Q. Between 1890 and your next survey in 1892, had a good portion of this river been levied?

A. There had been one or two levee districts in there.

There was one at Pekin, that was started, I think. No sir, not a good portion of it.

Q. About what portion of it then?

A. There were small levee areas, comparatively small.

Q. How many levee districts are there now?

A. There is one opposite Pekin.

Q. About how many miles does that one at Pekin include?

12003 A. About 2 miles long or something like that—1½ miles long. If I had my maps here I could show you.

Q. Approximately?

A. I should think 1 1-2 or 2 miles long.

Q. That is opposite Pekin?

A. Yes sir, then there is one opposite Beardstown, that I should think was perhaps 2 miles or 2 1-2 miles long, and there is now, which was not in 1892, there is one opposite Havana. That was not there in 1892. It has been put in since. I should think that is perhaps a couple of miles long. There is one above Kampsville, on east side of the river.

Q. Was that erected since 1892?

A. No sir, that was prior to 1890. That is a low levee, however, and in 1892 it was all over flowed, went over the top of it. I know that district very well because I stopped at the house with the party who owns the land. It overflowed there in 1892 but not in 1890. I think that is all that I can recollect.

Q. Is there a general effort being made by the people along the banks of the Illinois River to erect those levee districts?

A. Only at certain places. I would not consider it was 12004 profitable for them to at other places.

Q. In making your estimate as to the number of acres of land subject to overflow along the banks of the Illinois River or contiguous to the banks of the Illinois River what do you mean by the phrase "subject to overflow?"

A. That which would at any time be overflowed. That which has in the past been overflowed.

Q. At times of an unusual freshet?

A. Yes sir, that is what I took it to be.

Q. There is a vast volume of water in there?

A. Yes sir, such as 1892.

Q. At that time the water was very high all over the country?

A. Yes sir, an unusual flood at that time.

Q. And in making your estimate you take those matters into consideration, that of an unusual volume of water?

A. Yes sir, 1892 was an exceptional flood in the Illinois River.

Q. Not only in the Illinois River but in its tributaries?

A. But in its tributaries.

Q. And in all parts of this country?

A. Yes, sir, 1892 was an exceptional flood year.

12005 RE-DIRECT EXAMINATION, By Mr. Todd:

Q. Do you know whether the Pekin Levee Company washed out in 1902?

A. The levee broke and all that country was overflowed.

Q. And was turned into a carp pond?

A. I believe it did. That is my recollection of it. In 1902? It broke in 1892. I do not know about 1902. I had reference to 1892. My impression is it broke in 1892.

Q. These several levee districts to which you refer have they withstood the floods along the Illinois River?

A. No sir. No sir, they did not withstand the flood of the Illinois River. The one opposite Beardstown is the best one I know of along the river. That is the heaviest.

Q. Has that withstood the floods since its construction?

A. I believe it has broken once. I do not know which year. That is only hear say.

Q. These levee districts contain about 1,000 or 2,000 acres which are levied off from the bottom lands do they not?

A. I think the one opposite Beardstown contains more.

Q. How much more?

12006 A. This is mere calculation. I think they have something between 3,000 and 4,000 acres. I could give all that more accurately if I had my maps here.

Q. I only want it approximately. From your knowledge of the Illinois River do you know of any concerted movement to levee that river from its mouth to La Salle?

A. No sir, the levees have been erected, as I understand it, only by private parties, for the purpose of tilling the ground within the levee area.

Q. As a practical proposition do you believe the Illinois River could be levied for the purpose of creating any value to the land lying behind such levees that the cost of the levees would not exceed the cost of the land?

A. I would not consider it a good commercial proposition to levee the Illinois River for tillable purposes except here and there, just as they have selected and placed locations.

Signature waived.

12007 LEONARD P. KINNICUTT.

a witness on behalf of the defendants, being duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, By Mr. Todd:

Q. What is your name?

A. Leonard P. Kinnicutt.

Q. What is your business?

A. Director of the Chemical Department of the Worcester Polytechnic Institute.

Q. Where located?

A. Located in Worcester, Massachusetts.

Q. Where were you educated, Professor?

A. I graduated at the Massachusetts Institute of Technology, in 1875, with the Degree of Bachelor of Science. I studied in the University of Heidelberg, for two years, under the direction of Professor Bunsen. I then studied two years at the University of Bonn, Germany, in the laboratory of Professor Kekule. I then studied for four months at Johns Hopkins University, then at Harvard University, where I obtained the degree of Doctor of Science.

12008 Q. Since graduation what have you done?

A. Since graduation, or since receiving my Doctor of Science degree I was instructor in Chemistry in Harvard University for three years. I was then appointed Assistant in Chemistry at the Worcester Polytechnic Institute. After three years I was appointed full Professor of Chemistry and then Director of Department of Chemistry in the Worcester Polytechnic Institute, which office I now hold.

Q. Have you had any positions with any Boards of Health or societies for the development or advancement of science?

A. I have been consulting chemist to the Worcester Board of Health since 1885. I was the consulting chemist to the Connecticut Sewage Commission, appointed by the Legislature. I have been for fifteen years fellow of the American Association for the Advancement of Science, of which I am now one of the vice-presidents. Member American, English and German Chemical Societies; member American Bacteriological Society, etc.

Q. Have you made a special study of sanitary problems?

A. I have made a special study of sanitary problems, beginning in the year 1882, which study I have continued from that time.

Q. Have you made a special study of the analysis of water?

A. I have made a special study of the analysis of water,
12009 both chemical and bacterial analysis of water, and I am
continually employed in making such determinations.

Q. Have you had any experience in the interpretation of bacterial and chemical analysis of water?

A. I have, as all water analyses require the interpretation of both chemical and bacterial results.

Q. What experience have you had in passing upon the water supply of cities?

A. I have had experience in passing on the water supply of numerous cities, among which I can name Gardner, Mass.; Quincy, Mass.; Bristol, R. I.; Warren, R. I., and various other towns and cities in the East.

Q. Have you made a special study of bacteriology as applied to water investigations?

A. I have made a special study of bacteriology as applied to water investigations, as such study is necessary for determining the character of a water.

Q. Have you made a study of the typhoid bacillus as related to the water supply?

12010 A. I have made a study of the typhoid bacillus as related to water supplies of the coli bacilli, and also the typhoid fever death rates of cities whose water supplies I have examined.

Q. Have you studied the colon bacillus?

A. I have studied the coli bacillus in the determination of the character of water supplies as that is one of the most important single determinations that we make.

Q. Is the typhoid fever bacillus related to the colon bacillus, and if so in what way?

A. The typhoid bacillus is very closely related to the coli bacilli, both belonging to the colon group, and can only be distinguished from each other by special tests.

Q. Are you acquainted with the physical conditions of the Chicago River, the Drainage Canal, the Desplaines and the Illinois Rivers and the Mississippi River, from Chicago to St. Louis?

A. I am.

Q. What opportunities have you had for becoming acquainted with the water course between Chicago and St. Louis?

12011 A. In September of last year I passed through the drainage canal on a tug boat, that went as far down as Joliet, noticing the Desplaines River. Took the train to Peru, then took the boat at Peru and journied down the river as far as St. Louis. I have my notes with me.

Q. Will you describe briefly the physical conditions of the Illinois River as you saw it?

A. The Illinois River as I saw it was a river without swift current, containing a large number of lakes. Below Peoria the shores were low and below Havana the lower part of the river looked like a series of lakes.

Q. Will you state in full what experience you have had in passing judgment upon water supplies of cities?

A. I might state that I make continuous analysis of the Worcester water supply, determining the number of coli in the laboratory each day. Then, I have been employed in determining the character of the water supplies of Quincy, of Bristol and Warren, of Gardner, of the character of the water in Lake Quinsigamond, which is near Worcester, to see if it was suitable for water supply in an emergency.

12012 I have also made numerous examinations of various rivers as the Nashua River between Lancaster and Worcester, of the Blackstone River which is possibly one of the most polluted rivers in the United States, and I am continually making analyses and giving opinions regarding the drinking water of various towns in Massachusetts.

Q. Have you made a special study of the problem of sewage disposal?

A. I have.

Q. Have you studied these problems in the United States and elsewhere?

A. I have both in the United States and in England.

Q. Will you state in full what observations you have made and what studies you have carried out on the problems of sewage disposal?

A. My investigations on the sewage disposal problem began in 1882, when I was asked to give my advice to the city of Worcester regarding the disposal of the city sewage.
12013 Since that time I have devoted a great deal of my attention to the subject of disposal of sewage. I have conducted experiments of my own lasting through periods of over two years, on the question of purification of sewage by the septic tank, having a tank in continuous operation, holding over 1,500 gallons. I have visited all the sewage purification plants in Massachusetts, and have visited most of those in England.

Q. Just describe the plants you have visited in England?

A. I studied the disposal of the London sewage by chemical precipitation. I have studied the system of septic tank treatment and contact bed treatment as carried on at Manchester. I have studied the system of chemical treatment and land irrigation as carried on at Birmingham, etc., etc.

I visited, the first year it was put in operation, the first septic tank in England at Exeter and carefully studied its operation.

Since 1896 I have visited England every other year, studying what was being done in England regarding the methods of treatment of sewage.

Q. What have you done in this country in applying the knowledge which you obtained about the problems of the
12014 purification of sewage?

A. The principal application that I have made of my knowledge is at the Worcester Purification Plant, and describing and writing regarding the treatment of sewage for various scientific societies and scientific papers.

Q. Have you conducted a septic tank yourself?

A. I have. I have conducted an experimental septic tank which I already stated contained 1,500 gallons, making very careful experiments continuously for two years. I have also conducted experiments on a practical scale, in a large open septic tank holding over 250,000 gallons, analyzing the sewage, the effluent, the gas that was given off and studying the processes that took place in the septic tank.

Q. Will you describe a septic tank?

A. A septic tank is merely a tank through which sewage is allowed to pass slowly, the rate of flow of the sewage being regulated. As a rule the sewage as it enters the tank enters below the surface of the liquid and the outlet for the effluent is also beneath the surface of the liquid. These tanks can be either open or closed. By closed I mean covered by a
12015 roof either made of wood or of cement concrete. That is essentially what we mean by a septic tank.

Q. Will you describe the processes which take place in a septic tank?

A. The action of a septic tank is what is commonly known as hydrolysis, the breaking down of complex organic compounds by absorption or addition of water which in the case of a septic tank is brought about by the action of bacteria.

The organic substances contained in the sewage can roughly be divided into three classes, the albuminoids, the fats and the carbo-hydrates.

The albuminoids are organic nitrogen compounds of very complex composition. These compounds by hydrolysis are first resolved into peptones which are soluble in water and then further broken down, giving organic substances containing nitrogen and organic compounds, free from nitrogen.

In this process of breaking down of the albuminoids gaseous products carbon dioxide marsh gas, hydrogen, ammonia, nitrogen and probably more or less sulphide of hydrogen are formed.

The fats, by the same process are resolved into organic acids and glycerine, while the carbo-hydrates break up into alcohol and carbon dioxide.

12016 By this process of hydrolysis the complex organic compounds are broken down into simple compounds with the result that a certain amount of insoluble organic matter contained in the sewage is rendered soluble. A certain amount is removed from the sewage and the organic matter which remains is more easily acted upon by what are called the nitrifying bacteria.

The processes which take places in the septic tank might be called the process of putrefaction. The chief object of the septic tank is the breaking down of these complex compounds, of rendering part of the insoluble compounds soluble and removing part of the organic compounds by resolving them into the gases named and by making the organic compounds which remain, more easily acted upon by the nitrifying bacteria.

I might say the purification of sewage can be divided into two processes, the first process which can be described under the name of putrefaction being brought about by anaërobic bacteria; the second process, the nitrification process, being the further breaking up of these organic compounds and
12017 completely changing the organic into inorganic or mineral matter.

Q. In the operation of a septic tank, will septic operation take place in an uncovered tank?

A. The operation will take place, I believe, fully as well in an open tank as in a closed tank, and illustrating this I might state that at Birmingham, England, which has the largest installation of septic tanks, over 20 in number, all are uncovered and the opinion at the present time regarding the construction of the septic tanks is that open septic tanks will be used in the place of closed septic tanks on account of the difference in cost of construction, the process taking place fully as well in an open as in a closed tank. I might add that the only advantage of the closed tank is as regards the giving off of odor. There is less danger of nuisance from odors from a closed septic tank, than from an open septic tank.

As a rule in an open septic tank a crust forms over it which

acts as a cover. In a great many cases, however, this coat-
12018 ing does not appear or where it does appear it is thin and
is easily carried from one part to another part of the tank.

I might say that in the Worcester tank that a crust first appeared after the tank had been in operation one month. It increased in thickness for about two months and then during a wind storm it was borne to the further end of the tank, and carried away in the effluent, and no crust appeared on the top of the tank for over six months. At the present time in the Worcester tank the first portion of the tank is coated and the lower two-thirds are free from crust.

I would like also to add to that, that during the time that the Worcester tank was perfectly free from crust, no difference could be seen in the action that took place in the tank from the analysis of the sewage and the effluent.

Q. Will you differentiate between the processes that take place in the septic tank in the purification of sewage and the processes which take place in the running stream?

A. In the processes which take place in a septic tank are the processes which may be discribed under the general term of putrefaction which are brought about by anaerobic bacteria.

If sewage is delivered into a running stream and there
12019 is in the stream an excess of oxygen, two processes will
take place, the anaerobic putrefaction and then the nitrification of the sewage, or in other words, if sewage be delivered directly into the running stream both processes are taking place more or less at the same time, while in the septic tank only the first process is taking place.

Q. Have you studied the drainage canal from the standpoint of the septic tank?

A. I have.

Q. What studies have you made upon the drainage canal in its operation as a septic tank?

A. As I passed along the sanitary canal in a tug boat from Chicago to Lockport I took particular notice of the indications of the sanitary canal acting as a septic tank. Among the chief indications that it was so acting was that gas was being given off and I noticed bubbles of gas given off from the liquid as far as Lemont. After passing Lemont I noticed no further gas de-

velopment taking place. The odor from parts of the sanitary canal, especially near Chicago, remind you of the odor
12020 from the septic tank. Further down there was the odor that you obtain where the effluent of a sedimentation tank passes over or is allowed to fall over rocks or passes over a dam.

Q. Have you prepared any table showing the septic operation taking place in the sanitary canal?

A. I have.

Q. Will you state in what manner the tables were prepared?

A. I will. They are tables A., B., C,. D. and E., and follow here the explanation of them:

12021 In studying the action that takes place in the sewage during its passage through the canal, it is necessary to compare the analyses made at Kedzie Avenue or at Western Avenue Bridge with those made during the same period of time at the Controlling Works at Lockport. The averages of weekly examinations made by Prof. Palmer and those made by Prof. Jordan at these two points, and printed in "Streams Examinations, 1903," do not, as made out, give the required data.

Prof. Jordan's Table 119, "Streams Examination," gives the results obtained at Kedzie Avenue from April 30th to June 25th, and his Table 123, "Streams Examination," gives the results obtained at Bear Trap Dam, Lockport, from April 15th to June 25th. Leaving out of this last table, the results of analyses made before April 30th, comparable data are also obtained. These data are given in Table A. Table 39, Palmer's, gives the average results of examinations made at Kedzie Avenue from Jan. 11th to Oct. 8th, 1900, while Table 43, Palmer's, gives the average results only from July 9th to Oct. 5th. By omitting the results obtained at Kedzie Avenue from Jan. 11th to July 9th, and determining the average results obtained from
12022 July 9th to Oct. 5th, data are obtained for comparison of the effect on the sewage during its flow through the canal. (These data are given in Table B.)

Prof. Long's Table 43, page 48, "Illinois State Board of Health, 1901," the analyses of water at Drainage Canal at Western Avenue from June 4th to Sept. 4th, 1900, and Table 44, the analyses of water of canal at Lockport, both covering the same periods of time, were taken as given. These data are also given in Table C.

(Table D is computed from tables A. B. & C.)

12023

TABLE A.

Analyses Showing the Changes Which Took Place During the Passage of the Sewage of Chicago Through the Sanitary Canal.

Jordan's Analyses. April 30—June 25, 1900.
Tables used, 119 and 123 Streams Examination.

Constituents.	Parts per million.

12028 In regard to table D, I would like to state that I was unable to obtain the mean of Jordan, Palmer and Long's results regarding soluble and suspended albuminoid ammonia, as Long made no determinations of suspended and soluble albuminoid ammonia. Further, that the total amount of albuminoid ammonia removed 22.9 per cent. as declared from the mean of Jordan and Palmer's analyses does not agree exactly in the per cent of total albuminoid ammonia removed, as given by mean of Long, Jordan and Palmer's analyses. The difference, however, is only one per cent.

Q. Will you state what conclusion you draw from the tables which you have introduced in evidence as to the septic action that takes place in the sanitary canal?

A. If analyses are made of the crude sewage, and of the effluent from the septic tank we find that as a rule the amount of free ammonia in the effluent is greater than in the sewage; that the amount of total or soluble albuminoid ammonia and of suspended albuminoid ammonia is less in the effluent than it is in the crude sewage; that the amount of nitrogen as nitrates and nitrites is very small in the effluent and as well as in crude
12029 sewage, but there is a reduction of nitrogen as nitrites and nitrates.

From the analysis that I have made showing the character of the water at Lockport and the character of the water in the canal at Kedzie Avenue, these results indicate very strongly that the septic action has taken place during the passage of water containing sewage through this canal, as shown by the increase in free ammonia, the decrease in albuminoid ammonia, soluble albuminoid ammonia, also in the decrease in oxygen consumed, soluble and suspended; that the results agree in their general characteristics with results that have been obtained by the examination of crude sewage and the effluent from the septic tank in the various places that I have given in table E. The changes are exactly the same in character, the difference only being in amount.

Q. Have you made any comparisons between the action which takes place in the sanitary canal with that which takes place in septic tanks at other places?

A. I think the answer to this question I have just given in referring to table E. i. e., that the action seems to be the same as the action which takes place when sewage is passed through a septic tank.

12030 Q. What effect does this septic action, as you have described it, have upon the sewage of Chicago as it passes through the drainage canal?

A. It has a purifying effect. It also renders the substances which still remain in the sewage more easily acted upon when the sewage enters the river, and it purifies the sewage by removing a part of the solid matter that was in the sewage by throwing it down to the bottom of the canal and by the removal of part of the solid matter by changing it into gas.

Q. What effect does the septic action which you have described as taking place in the drainage canal have upon the bacterial life of the sewage, both the pathogenic and non-pathogenic?

A. Very little work, as far as I know, has been done regarding the action of the septic tank on bacterial life. The best experiments which I know of which are reported are given in the second report of the Royal Commission on Sewage Disposal, 1902, appointed in 1898, which inquired and reported what methods of treating and disposing of sewage may be properly adopted.

The report of Professor Boyce upon the treatment of
12031 Manchester, England sewage by means of bacterial beds,
pages 11 and 12 of the report quoted states "experiments made in Manchester show that B. coli diminshes during the stay in the septic tank, and experiments conducted in the laborartory show, that the septic tank liquid is inimical to B. coli, and therefore to other more delicate bacteria."

He also gives some experiments made by him showing that B. coli diminish in the septic tank.

Thus in one series of observations at Manchester the average number of B. coli was, December 15, 1900, crude sewage 5011; the septic tank 2130.

The Cameron tank which is merely a closed septic tank is 2099.

Experiments on April 3, 1900, he gives crude sewage 45,600; septic tank 7433; septic tank liquid after 2 days 2025; Then he gives quite a series of experiments and a table showing the effect of B. coli at Manchester and Leeds which, show a reduction of the coli in the septic tank.

I will say that my own opinion is that it diminishes the number of B. coli and the more delicate pathogenic germs and
12032 that the total number of bacteria is diminished by ten
or fifteen per cent.

Q. Have you given special attention to the chemical analysis of water for the purpose of ascertaining the sanitary quality of water?

A. I have made many such investigations of waters to determine the sanitary character of such waters.

Q. What determinations do you employ in your chemical analysis for ascertaining the sanitary quality of water?

A. The total solids; the suspended solids; the soluble solids; the nitrogen as free ammonia; the nitrogen as albuminoid ammonia; the nitrogen as soluble albuminoid ammonia and suspended albuminoid ammonia; the nitrogen as nitrites; the nitrogen as nitrates; oxygen consumed; the chlorine; the hardness and some times the total nitrogen. From the total of solids in connection with the hardness, the character of the water for household use, not including drinking or cooking purposes--from the suspended solids the amount of sediment in the water.

Q. What conclusions do you draw from the presence of these different chemical elements when found by your determinations?

12033 I draw the following conclusions:

CHLORINE

Contained in water, chiefly as salt occurs in small quantities in all soils and is consequently present in all waters, streams, ponds, lakes, wells, etc. Most animal matters, especially animal secretions as urine, contain salt. It is also contained in the kitchen waste, in the waste products of many manufacturing processes, and is therefore a constant constituent of sewage. When it enters a stream it does not undergo any decomposition or change, and the only natural causes of change in the proportion of chlorine in a water is through evaporation of the water by the sun's heat, the addition of water containing larger amounts of chlorine as sewage water or by dilution with water containing less chlorine than the water in the stream. The determination of chlorine is an index to the total chlorides introduced into a stream from whatever source above the point at which the determination is made. A sudden increase in chlorine in a stream tends to show the addition of sewage. A sudden decrease, the dilution of the water of the stream by purer water. Normal chlorine of Lake Michigan is 2 parts of some of the rivers, as the Fox, it is 4 parts per million. The chlorine

12034 serves as an index to the past history of the water.

ALBUMINOID AMMONIA.

Albuminoid ammonia indicates the amount of decomposable nitrogenous substances like albumen or protoids in a water. These substances are contained in large amount in sewage and serve as food material for bacteria. These nitrogenous substances are also contained in vegetable matters like dead leaves, grasses, algae, etc., and the amount of albuminoid ammonia not only indicates that the undecomposed matters from sewage are contained in a stream, but also may indicate these other named substances. Something regarding the character of the water must be known before a perfectly correct idea of the significance of albuminoid ammonia is arrived at. In the examination of any given stream it can be said that the decrease of albuminoid ammonia shows that purification is taking place, and that the decrease of albuminoid ammonia shows a decrease of bacterial food, and is in general co-incident with bacterial purification.

FREE AMMONIA.

Free ammonia or saline ammonia is found in small quantities in all waters coming from rain, snow, and the wash-
12035 ings of the soil. In fresh sewage it is contained in com-
paratively large quantities and often in still larger quantities in sewage in which the first changes of putrefaction are taking place, i. e., decomposition of nitrogenous organic matter by anaerobic bacteria. It comes into sewage from the urine and dejecta of men and animals, from manufacturing waste and from the decomposition of these compounds. It also comes into water from the decomposition of micro-organisms and from green plant life like algae. An increase in the free or saline ammonia in the stream may be due to the entrance of sewage or to the decomposition of plant life. A decrease to dilution by its being changed by nitrifying bacteria into nitrites and nitrates. A study or knowledge of the water shed of a stream is often necessary for the proper interpretation of free ammonia results.

NITRITES.

Nitrites in a water usually indicate that the ammonia is being changed into nitrogen as nitrites, though it is contained in small amounts in rain and snow, and to a certain extent comes

into the water in this way, or from washings from surface
12036 soil. It may also be derived from the reduction of nitrates
in water by certain bacteria. Nitrites to any amount in a stream indicate that the purification process is actively taking place. A decrease in nitrogen as nitrites with increase of nitrogen as nitrates shows that the final stage or removal of organic matter is taking place.

NITRATES.

Nitrogen as nitrates in a water are usually formed from the nitrites in the water and indicate the last stage in the removal or oxidation of organic matter in a stream. A water may be sanitarily a perfectly pure water and yet contain a large amount of nitrates. Nitrates in a water taken by themselves indicate the past history of the water. If in an examination of a stream we find nitrogen as albuminoid ammonia decreasing and nitrogen as nitrates increasing, it shows that self-purification, so-called, of the stream is taking place. Decreasing nitrates may be due to algae life.

TOTAL ORGANIC NITROGEN.

The amount of nitrogenous matter in a water is also indicated by what is called total organic nitrogen. This is the
total amount of nitrogen contained in the nitrogenous
12037 substances in the water, and from it an idea as to the
amount of nitrogenous matter in the water can be determined. The general factor used to multiply the amount of total organic nitrogen to obtain the amount of total nitrogenous matter is 16.3. The nitrogen as albuminoid nitrogen gives as a rule only one-half the total nitrogen contained in nitrogenous matter.

OXYGEN CONSUMED.

By oxygen consumed is meant the amount of oxygen used for the destruction of or oxidation of substances contained in water. It serves as an index as to the amount of carbonaceous matter in the water, and in stream examinations it shows the amount of oxidizable matter contained in the water.

12038 The so-called nitrogen cycle is a representation of the changes that take place in the nitrogenous products when contained in water, the albuminoid ammonia being first changed into free ammonia, the free ammonia then being changed into nitrogen as nitrites and nitrates. The green plant life which is always contained in stream water decomposes the nitrates, taking part of the nitrogen to build up their own tissues, part of the nitrogen being given off in a free state. These algae undergo decomposition and give again albuminoid ammonia. The albuminoid ammonia is then changed into free ammonia, and the cycle so continues. This may take place a number of times in a river water.

Q. Have you studied the chemical data prepared by Professor Long and published in the Board of Health reports of the State of Illinois, which have been introduced in evidence in this case, and the chemical and bacterial data prepared by Professor Jordan, Professor Palmer, Professor Burrill and Professor Zeit?

12039 A. I have.

Q. Have you examined the tables prepared by Professor Long and published in the Board of Health reports of the State of Illinois, which have been introduced in evidence in this case?

A. I made a careful examination of the tables of Professor Long as given in the Illinois State Board of Health reports, in 1901, and introduced in this case.

Q. Will you state what conclusions you draw as a chemist and sanitarian from the analytical data presented in such tables by Professor Long?

A. I have taken the analytical data as given by Professor Long in the Illinois State Board of Health, 1901, which are the results of his examinations of the water at the various stations from Chicago to Grafton on the Illinois River, both for 1899 and 1900. The results of his analysis from June to December, 1899, with the conclusions drawn from those results are as follows:

12040 Table 1.—Analyses of Lake Michigan tap water, July 17—Nov. 27, 1899. The total solids are 144, suspended 2, and soluble 142 per million. The free ammonia is 0.05, the albuminoid ammonia 0.103 and it contains no nitrogen as nitrites or nitrates, total oxygen consumed 1.05, chlorine 1.77. Two analyses in July, one in August and two in November.

Table 2.—Bridgeport. Pumping station, July 1st to Nov. 27, 1899, weekly examinations. The results are such as would be obtained from dilute sewage. Total solids 536.5, soluble solids 473, suspended solids 63.5; free ammonia 19.84, albuminoid ammonia 3.32, nitrogen as nitrites 0.03, nitrates 0.0, oxygen consumed 26.65, chlorine 95.47.

Table 3.—Lockport Canal, July 3rd—Nov. 29th. The results obtained at this point are very similar to the results obtained at Bridgeport during the same period, and show that during its passage through the canal little change has taken place in the sewage.

Total solids 558, soluble 491, suspended 67; free ammonia
12041 19.85, albuminoid ammonia 3.37, nitrogen as nitrites 0.03,
nitrates 0.03, oxygen consumed 27.90, chlorine 96.97.

Table 5.—Joliet. Illinois and Michigan Canal, July 3rd—Nov. 6th. Total solids 591, soluble solids 487, suspended solids 104; Free ammonia 16.05, albuminoid ammonia 2.88, nitrogen as nitrites 0.015, as nitrates 0.014, oxygen consumed 25.69, chlorine 85.49. The distance of Joliet from Lockport is only four miles, and the results show that but little change has taken place in the sewage in its flow from Lockport to Joliet. The chief difference in results at this point from those obtained at Lockport, being due in my opinion to dilution by water of the Desplaines River which at this point is mixed with the waters from the canal.

Table 7.—Morris. Illinois River, July 5--Nov. 28. Total solids 445, soluble solids 420, suspended solids 25, Free ammonia 10.99, albuminoid ammonia 1.20, nitrogen as nitrites 0.18, nitrogen as nitrates 0.07, oxygen consumed 9.16, chlorine 61.8.
12042 Morris is about 24 miles from Joliet. The Kankakee
river enters the Desplaines River about nine miles above Morris and its diluting effect is shown by the reduction of chlorine from 85.49 to 61.8. The water of the Kankakee River is a much purer water than that of the Desplaines River at the point of junction, and so the water of the Desplaines is purified to a certain dgree by dilution. That the organic matter in the water has begun to undergo decomposition is shown by the de-

crease in free and albuminoid ammonia and increase in nitrogen as nitrites and nitrates. There has also been a decided deposition of suspended matter, a large part of which was oxygen consuming substances, as the suspended oxygen consumed at Joliet is 10.59, while at Morris it is only 1.09.

Table 8—Ottawa. Illinois River, July 5th—Nov. 27th.
Total solids 445, soluble solids 434, suspended solids 11, Free
ammonia 6.23, albuminoid ammonia 0.62, nitrogen as nitrites
0.61, nitrogen as nitrates 0.74, oxygen consumed 7.13,
12043 chlorine 57.4. There has been a very decided change in
the purity of the water in the river between Morris and Ottawa, a distance of about 24 miles. The chlorine shows that there has been very little dilution of the water of the river between these points, and the very decided decrease in free and albuminoid ammonia with increase of nitrogen as nitrites and nitrates shows that bacterial decomposition of the organic matter is rapidly taking place, changing the organic matter into mineral matter. There has also been a certain amount of deposition of suspended matter. Between Morris and Ottawa there is a dam, the Marseilles dam, I believe, but this would have little effect in the character of the water beyond bringing about the removal of suspended matter, there being, according to Prof. Palmer's results, dissolved oxygen in the water.

Table 10.—La Salle, Illinois River, July 13—Dec. 6. Total
solids 436, soluble solids 415, suspended solids 21, Free
12044 Ammonia 4.66, albuminoid ammonia, 0.58, nitrogen as
nitrites 0.35, nitrogen as nitrates 1.45, oxygen consumed
6.99, chlorine 41.3. These samples were taken about 600 feet above the mouth of the Big Vermillion, and although there has been some dilution as shown by the reduction in chlorine, the very decided decrease in free and albuminoid ammonia with corresponding increase in nitrogen as nitrates and the decided decrease in oxygen consumed shows that during the stretch of river between Ottawa and La Salle the processes of purification have been very active.

Table 12.—Henry. July 10—Dec. 4. Sample taken above the dam. Total solids 451, soluble solids 426, suspended solids 25, Free ammonia 3.28, albuminoid ammonia 0.553, nitrogen as nitrites 0.517, as nitrates 1.39, total oxygen consumed 7, chlorine

43.2. The slight increase in chlorine would indicate a slight
addition of sewage to the river, probably from La Salle and
Peru, total population 20,000. There has, however, been
12045 only slight changes between.

Table 13.—Peoria Narrows. July 5—Nov. 23. Total solids 422, soluble 398, suspended solids 24, Free ammonia 0.895, albuminoid 0.572, nitrogen as nitrites 0.141, nitrogen as nitrates 1.10, oxygen consumed 6.86, chlorine 33.04.

The chlorine shows that there has been more or less dilution between Henry and the Narrows, but the great change has been in the removal of free ammonia and nitrogen as nitrites. This shows that the principle change between Hanry and the Narrows has been the last process in the changing of the organic matters of sewage into mineral matter.

Table 14.—Wesley City. July 5—Nov. 29. Total solids 493, soluble solids 438, suspended solids 55, Free ammonia 4.36, albuminoid ammonia 3.20, nitrogen as nitrites 0.026, nitrogen as nitrates 0.106, oxygen consumed 17.44, chlorine 34.97. The increase in all the above constituents, especially the free ammonia, albuminoid ammonia and oxygen consumed, shows that a large amount of organic matter has been added to river between Peoria Narrows and Wesley City, a distance of only about six miles. This adition from my knowledge of the river is from the town of Peoria, 50,000 inhabitants, with its large cattle sheds and distilleries.

12046 Table 15.—Pekin. July 18th—Nov. 30th. Total solids 419,
soluble solids 393.0, suspended solids 26, Free ammonia
1.39, albuminoid ammonia 0.828, nitrogen as nitrites 0.273, nitrogen as nitrates 0.71, oxygen consumed 7.81, chlorine 34.76.

The distance to Pekin from Wesley City is about ten miles, yet in this stretch a great amount of purification seem to have taken place much more than I should have expected. This is shown by the very great decrease in free and albuminoid ammonia, oxygen consumed, and increase in nitrites and nitrates. There is no marked dilution as shown by the amount of chlorine.

Table 16.—Havana. July 6th—Dec. 14th. Total solids 432, soluble solids 381, suspended solids 51, Free ammonia 1.69, albuminoid ammonia 0.695, nitrogen as nitrites 0.21, nitrogen as nitrates 1.02, oxygen consumed 7.18, chlorine 29.17. The distance

from Wesley City to Havana is about 24 miles. Between the two places is a dam, known as Copperas Creek dam and a stream known as Mackinaw Creek enters the river. The samples were taken above Spoon River. There appears by the chlorine figure some dilution between Pekin and Havana. There is a slight increase in the free ammonia and in the nitrogen as nitrates, while the nitrogen as nitrites is slightly lower. We see here,
12047 as at Peoria Narrows the final changes of organic matter
into mineral matter taking place.

Table 26.—Grafton. July 10—Nov. 28. Total solids 362, soluble solids 306, suspended solids 56, Free ammonia 0.247, albuminoid ammonia 0.455, nitrogen as nitrites 0.044, nitrogen as nitrates 0.59, oxygen consumed 5.61, chlorine 17.5.

The distance from Havana to Grafton is 119 miles. There is a dam between Grafton and Havana and the water of the river is diluted by the Spoon and Sangamon Rivers, both of which enter the Illinois between Havana and Grafton. The water at Grafton, as shown by the analyses, has been so purified between Havana and Grafton that it now closely resembles the water at Peoria Narrows. It shows only in the chlorine and nitrogen as nitrates evidence of part pollution.

Table 21.—Grafton on the Mississippi, July 10—Nov. 20. Samples taken above the junction with the Illinois. Total solids 278, soluble solids 169, suspended solids 109. Free ammonia 0.08, albuminoid ammonia 0.443, nitrogen as nitrites 0.001, nitrogen as nitrates 0.03, oxygen consumed 8.52, chlorine 1.77. The river differs greatly from the Illinois in the amount of chlorine it contains, 177 against 17.5, and while it contains a less amount of solid substances in solution than the Illinois, it contains a greater amount of suspended matter. The amount of or-
12048 ganic nitrogenous matter and carbonaceous matter in the
two rivers is about the same, as shown by the albuminoid ammonia and oxygen consumed.

12049 I have also prepared tables from the results of Professor
Long's analyses at the various stations from Chicago to Grafton, from June to October, 1900, and they are as follows:

Table 41—Chicago City water, June 5—Sept. 4, 1900.
12050 Total solids 148, soluble solids 148, suspended none. Free
ammonia 0.016, albuminoid ammonia 0.094, nitrogen as ni-

trites none, nitrogen as nitrates trace, oxygen consumed 2.93, chlorine 2.17. Four analyses in June, five in July, four in August and one in September. These analyses would indicate that the water was not quite as pure in 1899 as 1900, but are results that would be obtained with a potable water.

Table 43.—*Western Avenue Bridge*, Drainage Canal, June 5—Sept. 4. Total solids 203, soluble solids 178, suspended solids 25, Free ammonia 1.34, albuminoid ammonia 0.95, nitrogen as nitrites 0.11, nitrogen as nitrates 0.12, oxygen consumed 6.28, chlorine 9.2.. If this is compared with the analyses of the water in the Illinois and Michigan canal in 1899 at Bridgeport it is seen that it is a very much more dilute sewage, or sewage mixed with a much larger amount of water.

Table 44.—Lockport Canal, June 4—Sept. 4. Total solids 212, soluble solids 193, suspended solids 19, Free ammonia 2.16, albuminoid ammonia 0.76, nitrogen as nitrites 0.06, nitrogen as nitrates, 0.00, oxygen consumed 5.29, chlorine 12.6. This analysis when taken in connection with table 43, as I have already pointed out, shows that the dilute sewage has undergone
12051 very decided changes in its passage through the canal.

Table 45.—Joliet, Desplaines River, June 4—Oct. 1. Total solids 280, soluble solids 245, suspended solids 35, Free ammonia 4.66, albuminoid ammonia 0.85, nitrogen as nitrites 0.09, nitrogen as nitrates 0.02, oxygen consumed 6.97, chlorine 31.4. This analysis shows that the water is not as pure as it been up there, but when compared with the analyses made in 1899, shows that it contains very much less organic matter than it did at that time.

Table 46.—Morris. June 4—Oct. 3. Total solids 251, soluble solids 222, suspended solids 29, Free ammonia 2.84, albuminoid ammonia 0.63, nitrogen as nitrites 0.27, nitrogen as nitrates 0.17, oxygen consumed 6.4, chlorine 17.8. The dilution by the waters of the Kankakee is here shown by the chlorine as in 1899. The water is very much purer than in 1899.

Table 47.—Ottawa, June 4—Oct. 16. Total solids 266, soluble solids 238, suspended solids 28, Free ammonia 0.81, albuminoid ammonia 0.39, nitrogen as nitrites 0.37, nitrogen as nitrates 0.92, oxygen consumed 5.94, chlorine 17.2. There has been even more marked purification of the water in its run of

24 miles in 1900 than 1899, as shown by the reduction of free albuminoid ammonia, and oxygen consumed, and by increase of nitrites and nitrates.

12052 That there has been little if any dilution is shown by the chlorine. The water is much purer than in 1899.

Table 49.—La Salle. June 4—Oct. 3. Total solids 278, soluble solids 252, suspended solids 26, Free ammonia 0.55, albuminoid ammonia 0.36, nitrogen as nitrites 0.25, nitrogen as nitrates 0.77, oxygen consumed 5.6, chlorine 15.8. The purification which was noted at Ottawa has continued. The chlorine shows the effect of slight dilution. River much purer than in 1899.

Table 51.—Henry, June 7—Oct. 1. Total solids 283, soluble solids 248, suspended solids 35, Free ammonia 0.41, albuminoid ammonia 0.4, nitrogen as nitrites 0.22, nitrogen as nitrates 1.06, oxygen consumed 5.86, chlorine 16.9. The results similar to those obtained in 1899, the slight increase in chlorine, indicates the addition of the sewage of La Salle and Peru. Slight changes as regards organic matter. River purer than in 1899.

Table 52.— Peoria Narrows, table 52, June 7—Oct. 9. Total solids 265, soluble solids 244, suspended solids 21, Free ammonia 0.21, albuminoid ammonia 0.34, nitrogen as nitrites 0.12, nitrogen as nitrates 0.95, oxygen consumed 5.05, chlorine 15.5 The change
as was the case in 1899, is the decrease in free ammonia,
12053 albuminoid ammonia and nitrogen as nitrites. Water much
purer than in 1899.

Table 53.—Wesley City, May 30—Oct. 10. Total solids 333, soluble solids 262, suspended solids 71, Free ammonia 1.62, albuminoid ammonia 1.34, nitrogen as nitrites 0.11, nitrogen as nitrates 0.72, oxygen consumed 9.91, chlorine 16.6. The analyses show the addition of the sewage of Peoria.

Table 54.—Pekin, May 30—Sept. 12. Total solids 326, soluble solids 250, suspended solids 76, Free ammonia 0.39, albuminoid ammonia 0.46, nitrogen as nitrites 0.17, nitrogen as nitrates 0.74, oxygen consumed 7.01, chlorine 15. As in 1899, a great amount of purification seems to have taken place between Wesley City and Pekin, a distance of 9 miles. River much purer than in 1899.

Table 55.—Havana, June 7 to Oct. 10. Total solids 322,

soluble solids 245, suspended solids 77, Free ammonia 0.41, albuminoid ammonia 0.41, nitrogen as nitrites 0.18, nitrogen as nitrates 0.77, oxygen consumed 6.46, chlorine 15. We have here in the 24 miles similar results to 1899, a very slight increase in free ammonia and in nitrates, and a slight decrease in albuminoid ammonia. Mackinaw Creek enters the river above
12054 Havana.

Table 58.—Grafton, June 7 to Sept. 24. Total solids 331, soluble solids 243, suspended solids 88, Free ammonia 0.07, albuminoid ammonia 0.36, nitrogen as nitrites 0.03, nitrogen as nitrates 0.87, oxygen consumed 5.85, chlorine 10.6. The water between Havana and Grafton has been so purified that the nitrates and chlorine are the only indications of the pollution of the river at Peoria.

12055 Table 59. Grafton on Mississippi River, July 31—Sept. 24. Total solids 347, soluble solids 152, suspended solids 195, Free ammonia 0.07, albuminoid ammonia 0.54, nitrogen as nitrites 0.02, nitrogen as nitrates 0.03, oxygen consumed 11.73, chlorine 2. The great difference in the Mississippi at Grafton from the Illinois at Grafton in 1900, as in 1899, was in the amount of chlorine 2 against 10.6, and in the suspended matter. The Mississippi, as shown by the albuminoid ammonia, and oxygen consumed contained in 1900 more organic matter than the Illinois in 1900 and figures for oxygen consumed show a greater amount of organic matter both in solution and suspension.

The data are, oxygen consumed.

	Total	Soluble	Suspended
Mississippi	11.73	7.08	4.65
Illinois	5.85	4.82	1.03

Q. Have you prepared any table from the chemical and
12056 bacterial analysis of Professors Jordan, Palmer, Burrill and Zeit, as they appear in Streams Examinations, which have been introduced in evidence in this case, and the tables of Professor Long as they appear in the Board of Health report of the State of Illinois, which also have been introduced in evidence in this case?

A. I have.

Q. Will you state in a general way the method employed by you in preparing the table which will subsequently be introduced in evidence by you at its proper time from the chemical and bacterial analysis of Professors Jordan, Palmer, Burril and Zeit?

A. Yes sir. The general method was to obtain the mean of the average of the analyses made by these various named persons during given periods of examination, as given in Streams Examination and the report of the State Board of Health of Illinois for 1901, which tables have already been introduced in evidence, and during times which were comparable with each other.

Q. In the examination of these tables did you strike an average for similar periods in different years of the analyses whose tables have already been introduced in evidence? 12057

A. I did.

Q. And where that method was not pursued your tables show it?

A. My tables show it.

Q. Have you prepared a table from the analytical data of Professor Jordan and Professor Palmer from May to January, 1899, and from January to May, 1900?

A. I have. I have prepared tables 41 to 52, inclusive, which are the mean of Jordan's and Palmer's results, May to December, inclusive, 1899.

Q. Will you produce and read the table prepared by you and as above described?

A. The tables are as follows, numbered 41 to 52, both inclusive

12058

TABLE 41.—ILLINOIS RIVER, 1899.

Palmer's S. E. 1901, Table 21, May 3—Dec. 27.

Q. Will you please state how these tables were prepared?

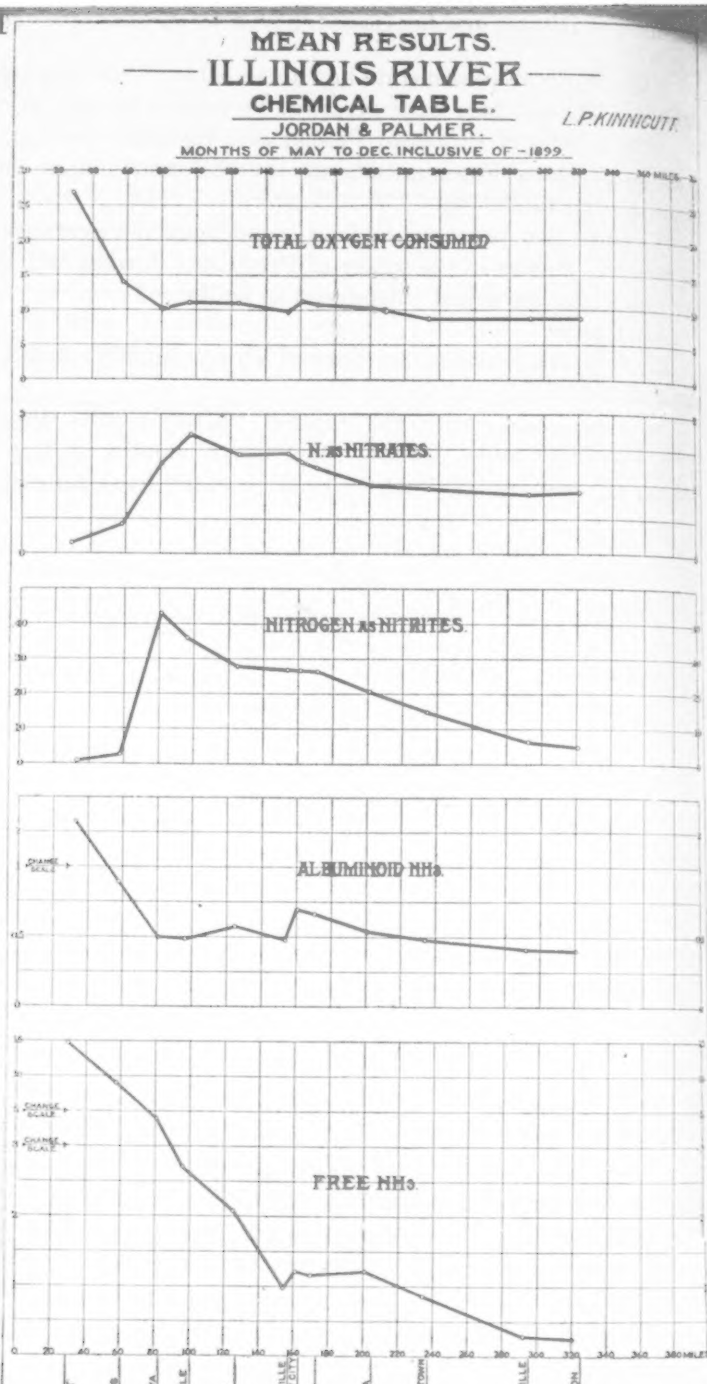
12070 A. These tables were prepared by taking the average of the results of Professor Palmer and Professor Jordan, as given in Streams Examination, at the different places mentioned in each table.

Q. Have you prepared a chart based upon the averages of the chemical results in the tables of Professors Jordan and Palmer which you have just introduced in evidence?

A. I have.

Q. Will you produce the chart which you have prepared, as above stated?

A. The chart, with the caption "Mean results Illinois River, Chemical table, Jordan and Palmer, months of May to December, inclusive, of 1899, L. P. Kinnicutt" is as follows:



MEAN RESULTS.
ILLINOIS RIVER
CHEMICAL TABLE.
JORDAN & PALMER.

Q. Will you state what the chart you have just introduced 12072 in evidence shows?

A. The chart that I have just introduced in evidence shows the amount of free ammonia, shows the amount of nitrogen as free ammonia, albuminoid ammonia, nitrogen as nitrites, nitrogen as nitrates and oxygen consumed as shown by the mean of the analyses taken at Joliet, north of Jackson Street on the Desplaines River, at Morris; at Ottawa; at LaSalle; at Henry; at Averyville; at Wesley City and Pekin; at Havana; at Beardstown; at Kampsville and at Grafton on the Illinois River, from May to December, inclusive, 1899, the mean results of Professors Palmer and Jordan. The abscisse gives the distance in miles of the various places from Chicago. The co-ordinates the part per million of the various substances.

Q. What sanitary significance do you draw from the chart just introduced?

A. At Joliet the high free ammonia, the high albuminoid ammonia the high oxygen consumed, the low nitrites and low nitrates show that at this point we have a water very badly polluted by organic matter or sewage. The rapid decrease in the amount of ammonia, free ammonia and albuminoid ammonia, and the oxygen consumed, from Joliet to Morris, and at the same 12073 time the increase in nitrogen as nitrites and nitrates shows the amount of purification that has taken place between these places. The most active zone of decomposition seems to be in the neighborhood of Ottawa. This is shown not only by the falling curves denoting free albuminoid ammonia and oxygen consumed but by the rising curves denoting nitrogen as nitrites and nitrates, the nitrite curve reaching its maximum at this point. As we proceed down the river from Ottawa to La Salle the curve shows continued purification. The slight fall in the curve from nitrogen as nitrates being due to the removal of nitrates from the water by green plant life. From La Salle to Henry the curve for the free ammonia and nitrogen as nitrites still descend. The slight rise in the curve for albuminoid ammonia and oxygen consumed indicates a slight addition of organic matter to the water of the river between La Salle and Henry. Below La Salle the purification continues down to

Averyville as shown by the gradual decrease of free and albuminoid ammonia, nitrogen consumed and nitrogen as nitrites.

At Averyville the chart shows, as was shown by Professor Long's table, the result of the final change of the organic 12074 to inorganic matter; low free ammonia; low free albuminoid ammonia; low nitrogen consumed with high nitrates. The results obtained by Long at Averyville from July 5th to November 25th, agree closely with the mean of Jordan's and Palmer's results from May to December, as is shown in the following table:

	Palmer—Jordan.	Long.
Total solids	388.9	422.0
Soluble solids	359.9	398.0
Suspended solids	29.0	24
Total oxygen consumed	9.8	6.86
Soluble oxygen consumed	8.2	5.46
Suspended oxygen consumed	1.6	1.2
Chlorine	41	33
Free ammonia	.97	.734
Albuminoid ammonia	.47	.47
Nitrogen as nitrites	.27	.141
Nitrogen as nitrates	1.45	1.1

Long's figures changed to nitrogen.

From Averyville to Wesley City we notice the effect of 12075 the contamination at Peoria by the rise in free ammonia, albuminoid ammonia, oxygen consumed and the decrease in nitrites and nitrates.

Jordan's and Palmer's results show less effect from this contamination than do Professor Long's analysis. This may be due to the possibility that at the point where Professor Long collected his samples, there may not have been complete mixing of the sewage of Peoria with the river water, or that where Palmer and Jordan's samples were taken there was not a complete mixing of the river water with the sewage.

Between Wasley City and Pekin the purification again begins and this purification is continued all the way down to Grafton where the low albuminoid ammonia, low nitrogen as nitrites, low oxygen consumed, shows the removal of the polluted matter entering the river at Peoria. If we again compare the results of Professor Long with the mean of Professor Jordan and Palmer we find a close agreement as regards the condition of the water at Grafton.

ADJOURNED until 2:00 P. M. of same day.

2:00 P. M. March 15th, 1904.

12077 Continuation pursuant to adjournment.

Present: The Commissioner and same counsel representing the respective parties.

LEONARD P. KINNICUTT,

resumed the stand for further examination by Mr. Todd, and testified as follows:

Q. Have you prepared tables based upon chemical analyses of Professors Jordan and Palmer, for the months from January to June, inclusive, for 1900?

A. I have.

Q. Were those tables prepared in the same manner as the tables already introduced in evidence by you?

A. They were.

Q. Will you please produce and read the tables which you have prepared?

A. The tables that I have prepared are numbered from 53 to 64 inclusive, and are as follows:

12078 TABLE 53.—ILLINOIS RIVER, 1900.

Q. Have you prepared a chart based upon the chemical results of Jordan and Palmer as they appear in the tables just introduced? 12090

A. I have prepared such a chart from the tables just introduced.

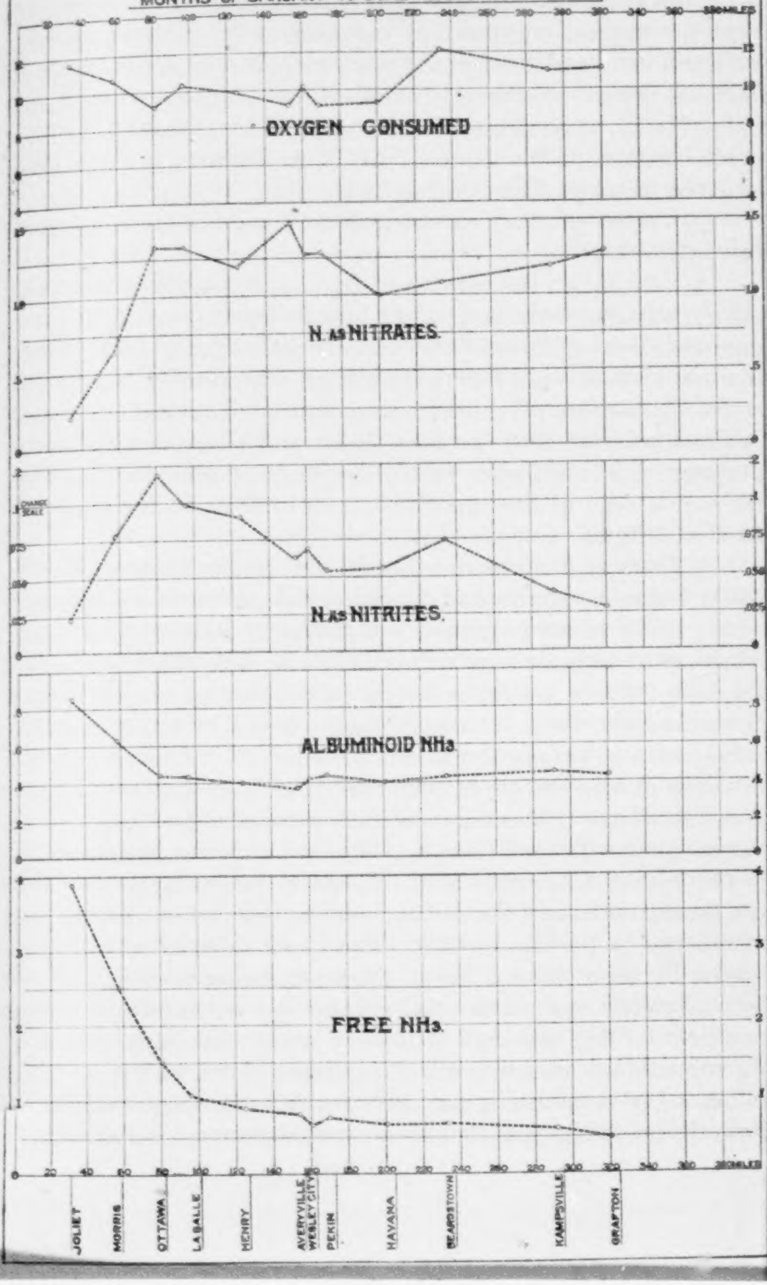
Q. Will you produce and make a part of your testimony such chart?

A. Such chart, with the Caption, "Mean results Illinois River Chemical Table, Jordan and Palmer, Months January to June inclusive, 1900, L. P. Kinnicutt," is as follows:

MEAN RESULTS.
ILLINOIS RIVER
CHEMICAL TABLE.
JORDAN & PALMER.

L.P. KINNICUTT.

MONTHS OF JANUARY TO JUNE INCLUSIVE OF 1900.



Q. Will you state what the chart shows?

12092 A. Chart 2 shows the amount of free ammonia, albuminoid ammonia, nitrogen of nitrites, nitrogen of nitrates, and oxygen consumed, as shown by the mean of the analyses made by Prof. Palmer, and Jordan, of samples taken at Joliet north of Jackson street on the Desplaines River, Morris, Ottawa, La Salle, Henry, Averyville, Wesley City, Pekin, Havana, Beardstown, Grafton, on the Illinois river, from January to June, 1900, as given in tables 53 to 64, inclusive.

Q. What sanitary conclusions do you draw from the chart just introduced?

A. At Joliet, the amount of free ammonia, albuminoid ammonia, oxygen consumed, is not half as great as in 1899, showing much less pollution of the water in 1900 than in 1899. There is, as in 1900, a rapid fall in the curves representing the amount of free ammonia, albuminoid ammonia, and oxygen consumed, in the stretch of river between Joliet and Ottawa, with corresponding rise in nitrogen as nitrites and nitrates, showing that the active zone of decomposition is as in 1899, in the neighborhood of Ottawa.

There is a slight increase in the oxygen consumed curve

12093 between Ottawa and La Salle. The albuminoid ammonia curve remaining nearly stationary, indicating a slight addition of organic matter to the water between Ottawa and La Salle. There is then a steady elimination of organic matter from the river down to Averyville, as shown by the gradual decrease of the curves for free ammonia, albuminoid ammonia, nitrogen as nitrites, oxygen consumed, with an increase of nitrogen as nitrates. The curve of free ammonia does not rise between Averyville and Wesley City, but the rise is noticed between Wesley City and Pekin. This may be due to the fact that the decomposition of the nitrogenous matter did not begin quite as quickly in 1900 as in 1899. The slight delay, a delay represented by about nine miles on the river, being probably caused by the lower temperature of the water in the winter and spring months of 1900, and it is also to be noted that the increase in the albuminoid ammonia curve continues down to Pekin, while in 1899 the decrease began between Wesley City and Pekin. From Pekin to Havana, there is a gradual decrease in the organic

nitrogenous matter, as shown by the free ammonia and albuminoid ammonia curve. From Havana to Kampsville the
12094 free and albuminoid ammonia increased very slightly and then decreased to Grafton. The nitrogenous nitrites and the oxygen consumed also rise slightly from Havana to Beardstown, then decrease between Beardstown and Grafton. The nitrogen as nitrites increased continuouslly from Havana to Grafton. The purification of the River from Havana to Grafton is indicated on the curves by the gradual increasing amount of nitrogen as nitrates. The decrease in free ammonia and albuminoid ammonia not being so evident on account of spring thaws and freshets.

Q. Taking the two charts which you have introduced, in consideration, the first for the months from May to December, inclusive, of '99, the second from January to June, inclusive, 1900, based upon the chemical results of Jordan and Palmer, as hereinbefore named by you, what sanitary conclusions do you draw from the comparison of the results as they appear upon these two charts?

A. The curves on the chart representing the river from June to January, '99, closely resemble the curves given
12095 on the chart representing the river from January to June, 1900, showing that the general character of the purification that took place is the same for the two years, the small differences being chiefly due to the effect of dilution and to seasonable variations that take place in the river. Both charts show by the rapid decrease of free ammonia, albuminoid ammonia and oxygen consumed, and increase of nitrogen as nitrites and nitrates, the purification that takes place between Joliet and Ottawa, in both years, and that the zone of the most active decomposition of organic matter has not been shoved, or been pushed further down the river by the increasing volume of the river, due to the opening of the Sanitary Canal. The purification is then shown to continue in both years as the river flows to Averyville, as shown by the decrease in the free ammonia, albuminoid ammonia, oxygen consumed and nitrogen as nitrites. The chart for June to January, '99, shows by the slight increase in albuminoid ammonia and oxygen consumed between La Salle and Henry that a certain amount of organic matter enters the

river at this point, but the continued decrease of free ammonia and nitrogen as nitrites indicates that it is either not very 12096 large in amount, or of a character not easily decomposed.

In both periods between La Salle and Henry, the nitrogen as nitrites shows a slight decrease, the nitrogen as nitrates also decreasing. The decrease of nitrogen as nitrates at this point is probably due to algae or green plant life. Between Henry and Averyville, the nitrogen as nitrites still decreasing, the nitrogen as nitrates shows an increase more marked between January and June, 1900, than between June and January, 1899. The reason for less increase in nitrogen as nitrates between Henry and Averyville between June and January than between January and June, is due to the larger amount of green plant life living in river waters in the summer and autumn months, than in the winter and spring months. The rise in free ammonia, albuminoid ammonia, and oxygen consumed, between Averyville and Wesley City show the pollution which enters the river between these two points in both years, which is removed in both years, as shown by the decrease in these substances as the river flows downward to Grafton. The river in both years, as shown by the curves, purifies itself again between Wesley City 12097 and Grafton, as it did between Joliet and Averyville.

The slight rise in free and albuminoid ammonia between Beardstown and Kampsville from January to June, 1900, is probably due to seasonal variations, as the river and pond waters contain more free albuminoid ammonia in the winter and spring than at any other time. In the lower stretches of the river in 1899 we find by the charts decreasing nitrites and nitrates; in the chart for 1900, we find, however, that while the nitrites decrease, the nitrates increase. This difference in nitrates in the lower stretches of the river is due to green plant life. This green plant life being more abundant in the summer and autumn months of 1899 than in the winter and spring months of 1900, removed, therefore, the nitrates to a much larger extent in 1899 than in 1900.

Q. Have you prepared a chart based upon the bacterial tables of Professors Burrill and Jordan, for the months of May and December, inclusive, for 1899?

A. I have.

Q. Will you produce and make a part of your evidence the chart thus prepared?

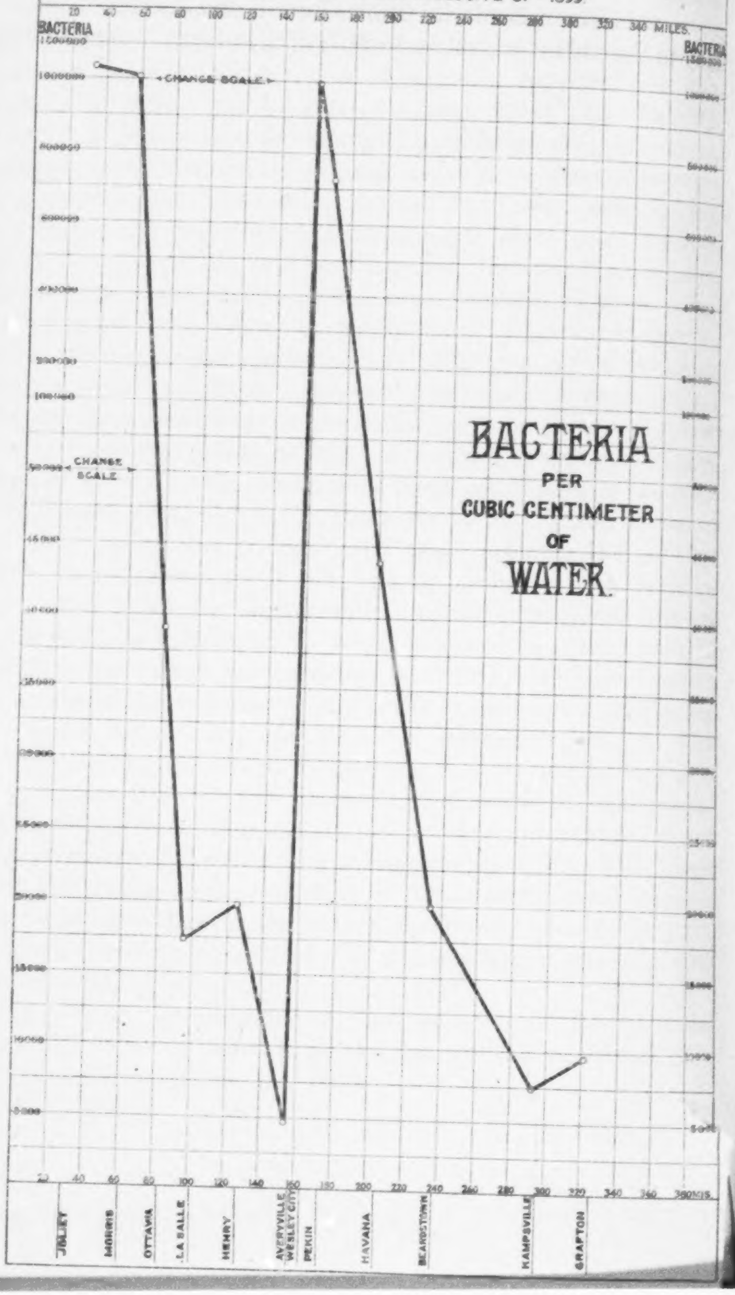
12098 A. The chart with the caption, "Mean Results, Illinois River, Bacterial Table, Burrill and Jordan, months of May to December, inclusive, 1899, L. P. Kinnicutt," is as follows:

12099

MEAN RESULTS.
ILLINOIS RIVER
BACTERIAL TABLE.
BURRILL & JORDAN.

L.P. KINNICUTT.

MONTHS OF MAY TO DEC. INCLUSIVE OF – 1899.



12100 Q. Will you state what the chart you have just introduced in evidence, shows?

A. This chart shows the number of bacteria as given by the mean of the analyses of Professors Burrill and Jordan of samples taken at Joliet, north of Jackson street, on the Desplaines, at Morris, at Ottawa, at La Salle, at Henry, at Averyville, at Wesley City, at Pekin, at Havana, at Beardstown, at Kampsville and at Grafton on the Illinois River from January to June, 1899. The abscissae give the distance in miles of various places from Chicago, the co-ordinates, the number of bacteria in one cubic centimeter of water.

Q. Will you state what sanitary conclusions you draw from the chart which you have just introduced in evidence?

A. The study of this chart, in connection with the chart for the chemical data of the same period, show a striking agreement between the chemical and bacterial data. The bacteria, which number over 1,000,000 per cc. at Joliet, decrease very rapidly to La Salle. In this distance, of about 62 miles, the number
has fallen from 1,000,000 to 17,412 per cc. This shows,
12101 as did the chemical results, that the zone of the great-
est purification is near Ottawa. There is a slight rise in the number of bacteria of only 2,000 per cubic centimeter between La Salle and Henry, a rise coinstant with the rise for albuminoid ammonia in the chemical chart for the same period. From this point the number falls steadily until Averyville is reached, the number there being 4,756 per cubic centimeter. Then on account of the pollution entering the river at Peoria, the number rises immediately to 995,503. This sudden rise in the number of the bacteria shows how quickly sewage pollution can be detected by bacterial examination. From this point the number of bacteria rapidly falls and at Kampsville there are only 7,457 per cubic centimeter, showing the great amount of purification that has taken place between Wesley City and Kampsville. Between Kampsville and Grafton there has been, as was the case between La Salle and Henry, a very slight increase in the number of bacteria, 2,005 per cubic centimeter. This increase is not at all significant, as a slight increase at this
point, after the rapid decrease between Wesley City and
12102 Kampsville is absolutely without significance as regards
the problem of stream purification.

Q. Have you prepared a chart based upon the bacterial tables which you have prepared from Burril and Jordan's tables, and which you have already introduced, for the months of January to June, inclusive, 1900?

A. I have.

Q. Will you produce the chart which you have thus prepared, making it a part of this evidence?

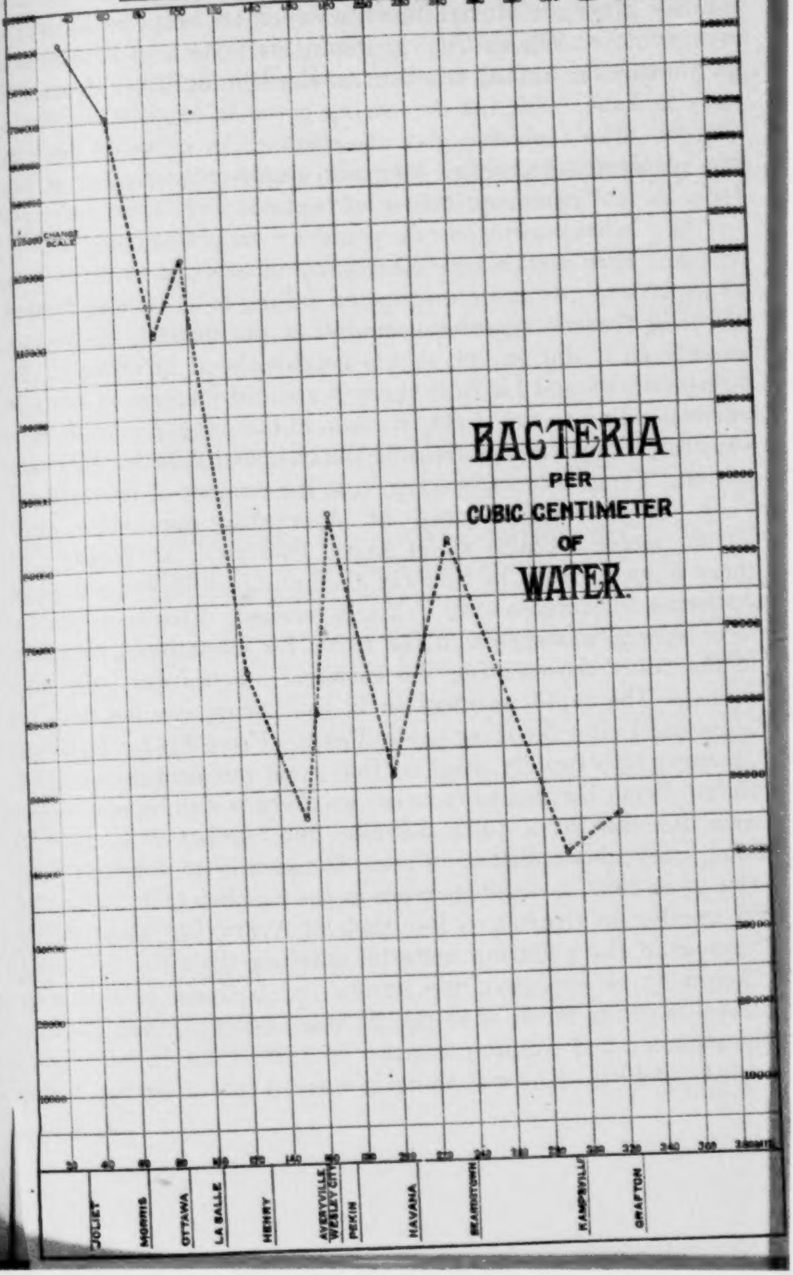
A. The chart with the caption, "Mean Results, Illinois River, Bacterial Tables, Burrill and Jordan, Months, January to June, inclusive, 1900, L. P. Kinnicutt, is as follows:

MEAN RESULTS.
ILLINOIS RIVER
BACTERIAL TABLE.

BURRILL & JORDAN.

L.P. KINNICUTT.

MONTHS OF JANUARY TO JUNE INCLUSIVE OF 1900.



12104 Q. Will you state what this chart shows?

A. This chart shows the number of bacteria as given by the mean of the analyses of Professors Burrill and Jordan, of samples taken at Joliet, north of Jackson street on the Desplaines River, at Morris, at Ottawa, at La Salle, at Henry, at Averyville, at Wesley City, at Pekin, at Havana, at Beardstown, at Kampsville, and at Grafton, on the Illinois River, from January to June, 1900, the data being given in tables 53 to 64, inclusive. The abscissae give the distance in miles of the various places from Chicago, the co-ordinates the number of bacteria in one cubic centimeter of water.

Q. What conclusions do you draw from this chart?

A. This chart shows the amount of bacteria at Joliet to be about 900,000 per cubic centimeter, falling to 110,000 at Ottawa, showing that the greatest amount of purification took place, exactly as it did in '99, in the neighborhood of Ottawa. Between Ottawa and La Salle there is a slight increase in bacteria, corresponding to the slight increase in the oxygen consumed, as shown in the chart representing the chemical data for this same period. From Ottawa to Averyville the number of bacteria rapidly decreases until at Averyville one cubic centi-
12105 meter contains about 45,000 bacteria. At Wesley City there is an increase in bacteria amounting to 60,000 and which continues to increase until Pekin is reached. This increase, due to pollution, was shown in the curve for albuminoid ammonia, in the chart representing the chemical curves for the same period. The rapid purification in the spring months does not begin until after the river passes Pekin. From Pekin to Havana the curve falls rapidly, showing that great purification has taken place. From Havana to Beardstown there is an increase in bacteria, followed by a quick decrease, the number at Kampsville being only about 40,000. From Kampsville to Grafton there was, as in 1899, a slight increase in the number of bacteria, but the number at Grafton is less than at Averyville, showing the removal of the polluting material entering the river at Peoria. As was to be expected, the number of bacteria in the lower stretches of the river, as shown by this curve, is greater during the summer and autumn months of 1899, than in the spring months of 1900. The soil bacteria washed into a stream during

the late winter and early spring months, always increases largely the number of bacteria in a river during that period.

12106 Q. Have you prepared tables showing comparisons of the sanitary character of the tributaries of the Illinois River, based upon the chemical results at their mouth, with the Illinois river, at Grafton, based upon the tables of Professors Jordan and Palmer, for the months of June to December, inclusive, 1899?

A. I have

Q. Were those tables prepared in the same manner with the other tables you have introduced in evidence?

A. They were, sir.

Q. Will you produce and read the tables which you have thus prepared

A. The tables are as follows, numbered from 65 to 72, inclusive.

12107

TABLE 65.–TRIBUTARIES TO THE ILLINOIS RIVER.

Desplaines River, 1899, *Lockport.*

Mean of Jordan's and Palmer's results for June–Dec.

	Parts per million
Total Solids	370.9
Soluble Solids	354.3
Suspended Solids.	16.6

Palmer's S. E. 1901, Table 21, June 7-Dec. 27.

12115 Q. Have you prepared a chart based upon the tables which you have just introduced?

A. I have.

Q. Will you produce the chart and make it a part of your evidence in this case?

A. The chart with the caption, "Mean Results, Comparison of the Sanitary Character of the Tributaries of the Illinois River at their mouths with the Illinois River at Grafton—Professors Jordan and Palmer, Months of June to December, inclusive, 1899," is as follows:

MEAN RESULTS.

COMPARISON OF THE SANITARY CHARACTER
OF THE TRIBUTARIES OF THE

ILLINOIS RIVER

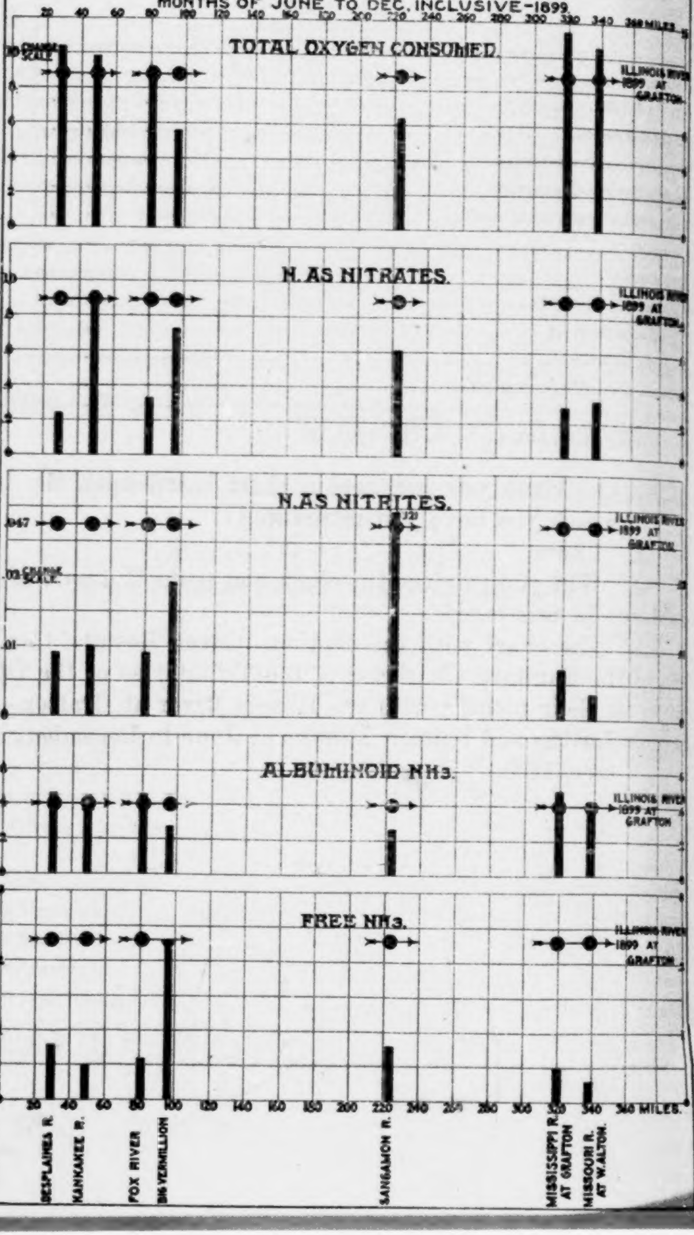
AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT

GRAFTON.

JORDAN & PALMER.

L.P. KINNICUTT.

MONTHS OF JUNE TO DEC. INCLUSIVE-1899.



12117 Q. Will you please explain the construction of the chart just introduced, and what it shows?

A. In this chart the amounts of free ammonia, albuminoid ammonia, nitrogen as nitrites and nitrogen as nitrates, total oxygen consumed, as found at the mouths of the Desplaines, Kankakee, Fox,. Big Vermillion, the Sangamon, the Mississippi river at Grafton, and the Missouri River at West Alton, are represented by columns, the top of the column representing the amount of the various chemical substances that I have just named in these various rivers. On this chart is also given by means of arrows the amount of free ammonia, albuminoid ammonia, nitrogen as nitrites, nitrogen as nitrates, total oxygen consumed at the mouth of the Illinois river, at Grafton, being the mean results of Prof. Jordan and Palmer's examination during the months of June to December, 1899, inclusive.

Q. What sanitary conclusions do you draw from the chart which you have just introduced, and the construction of which you have just explained?

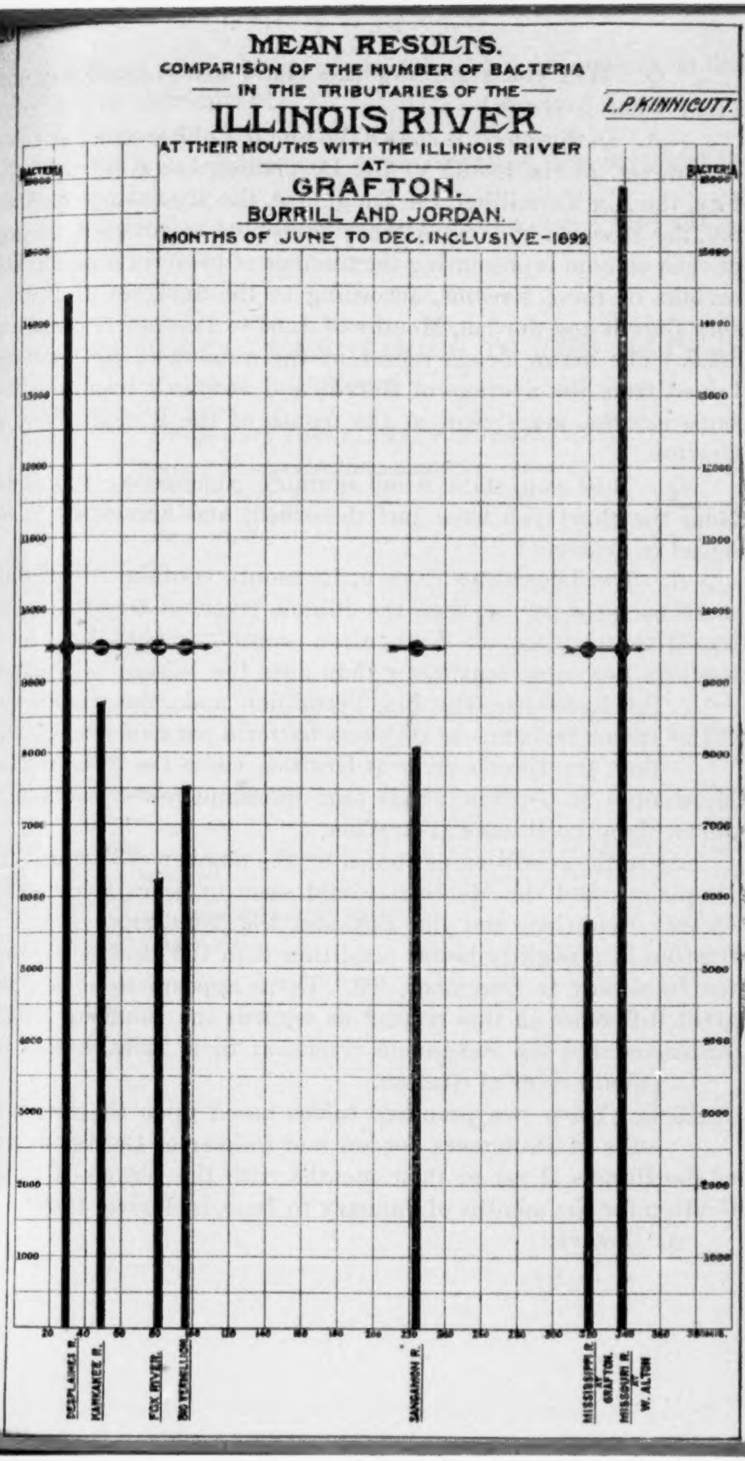
A. The chart requires very little explanation, as it is seen by the eye, that the waters of the Desplaines, the Kan-
12118 kakee, the Fox at their mouths, the Mississippi at Grafton, the Missouri at West Alton, contained in 1899 as much or more albuminoid ammonia and oxygen consumed than the Illinois at Grafton. The higher nitrogen as nitrates in the Illinois river, shows that the Illinois river at Grafton contained at one time higher up on the stream more organic matter, which has undergone decomposition, than did the other rivers. The free ammonia and nitrogen as nitrites is slightly higher in the Illinois at Grafton than in these other streams mentioned, with the exception of the Sangamon, but the amount in the Illinois is low, about 0.23 parts free ammonia and 0.047 parts nitrogen as nitrites, and is without any particular significance. As regards the purity of these streams, as shown by chemical charts and data, and by these curves, I should say that the waters of these various rivers were about in the same condition in 1899 as the Illinois river at its mouth, with the exception of the Missouri River at West Alton, which contains more organic matter.

Q. Have you prepared a bacterial chart from the same tables which you have just introduced, based upon the results of Professors Burrill and Jordan, for the months of June to December, inclusive, 1899?

12119 A. I have.

Q. Will you produce the chart thus prepared and make it a part of your testimony?

A. The chart with the Caption, "Mean Results, comparison of the number of bacteria in the tributaries of the Illinois river at their mouths, with the Illinois River, at Grafton, Burrill and Jordan, Months of June to December, inclusive, 1899, L. P. Kinnicutt," is as follows:



MEAN RESULTS.

COMPARISON OF THE NUMBER OF BACTERIA
IN THE TRIBUTARIES OF THE

ILLINOIS RIVER

AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT

GRAFTON.

BURRILL AND JORDAN.

MONTHS OF JUNE TO DEC. INCLUSIVE-1899.

L.P. KINNICUTT.

Q. Will you state how this chart was constructed, and
12121 what it shows?

A. In this chart is shown the number of bacteria per cubic centimeter, at the mouth of the Desplaines, the Kankakee, the Fox, the Big Vermillion, the Sangamon, the Mississippi at Grafton, the Missouri at West Alton, represented by columns, the top of each column representing the number of bacteria found at the mouths of these streams, according to the analyses of Professors Burrill and Jordan, Months of June to December, inclusive, 1899. The arrow heads represent the number of bacteria obtained from the average of Burrill and Jordan's results of the same months, same year, at the mouth of the Illinois river, at Grafton.

Q. Will you state what sanitary conclusions you draw from the chart you have just described, and heretofore introduced in evidence?

A. The Desplaines river at its mouth contains about 6000 more bacteria per cc. than the Illinois river, at Grafton, while the Missouri river, at West Alton, contains about 7000 more bacteria per cubic centimeter than does the Illinois at Grafton, the Kankakee, the Big Vermillion and the Sangamon
12122 rivers, from one to 2000 less bacteria per cubic centimeter than the Illinois river at Grafton, while the Fox, and the Mississippi at Grafton, about four thousand fewer bacteria to the cc. than the Illinois at Grafton.

As to the condition as shown by the number of bacteria, the Desplaines and the Missouri would seem to be in a less satisfactory condition, and the Fox and the Mississippi rivers at Grafton in a slightly better condition than the Illinois at Grafton from May to December, '99. There appears to be not any great difference in this respect as regards the condition of the Kankakee and the Sangamon rivers, at their mouths, and the Illinois river at Grafton.

12123 Q. Have you prepared tables based upon the mean results of Professors Jordan and Palmer of the tributaries of the Illinois River at their mouths with the Illinois River at Grafton for the months of January to June, inclusive, 1900?

A. I have.

Q. These tables were prepared in the same manner as the other tables introduced?

A. They were.

Q. Will you produce and read the tables thus prepared in evidence?

A. The tables are numbered 73 to 80, inclusive, and are as follows:

1212½ TABLE 73.—TRIBUTARIES TO THE ILLINOIS RIVER.

Palmer's S. E. 1901, Table 62, Jan. 4-June 25.

Q. Have you prepared a chart based upon the tables just introduced? 12132

A. I have.

Q. Will you produce and make the chart to which you refer a part of your testimony?

A. The chart, with the caption, "Mean results comparison of the sanitary character of the tributaries of the Illinois River at their mouths with the Illinois River at Grafton, Jordan and Palmer, months January to June, inclusive, 1900, L. P. Kinnicutt" is as follows:

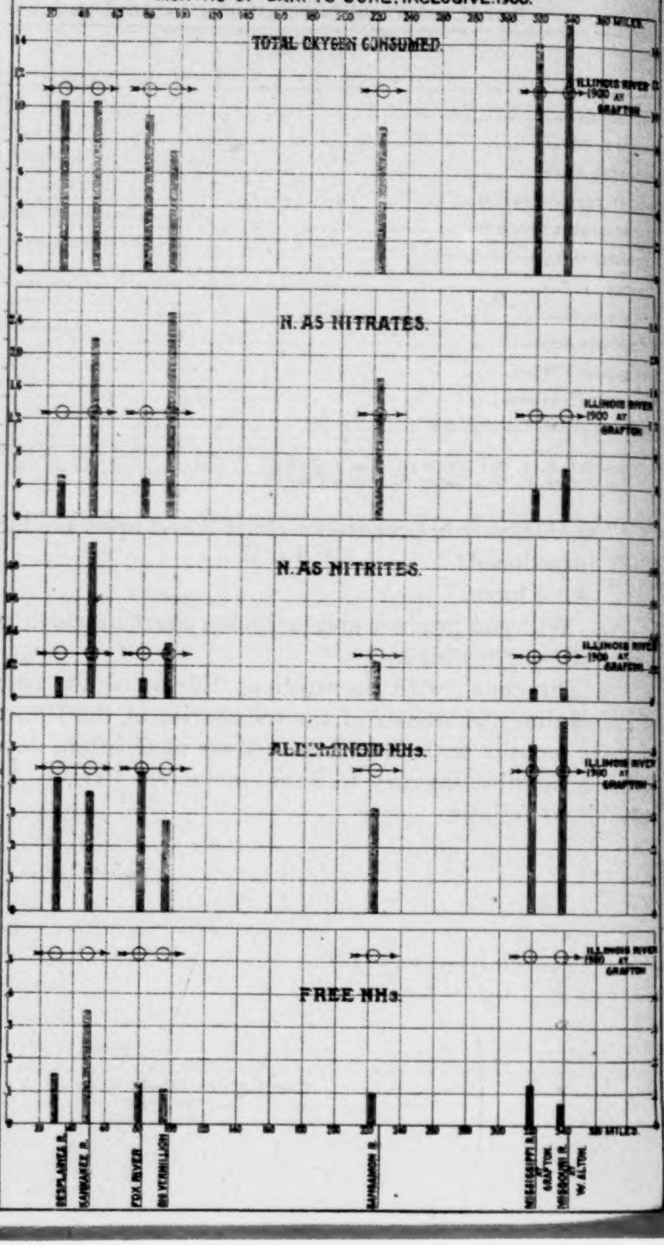
MEAN RESULTS.

COMPARISON OF THE SANITARY CHARACTER
OF THE TRIBUTARIES OF THE

ILLINOIS RIVER

AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT
GRAFTON.
JORDAN AND PALMER.
MONTHS OF JAN. TO JUNE, INCLUSIVE. 1900.

L. P. KINNICUTT.



Q. Will you state how this chart is constructed and what
12134 it shows?

A. This chart is prepared the same as the chart with the caption "Mean results, comparison of the sanitary character of the tributaries of the Illinois River at their mouths, with the Illinois River at Grafton, Jordan and Palmer, months June to December, inclusive, 1899, L. P. Kinnicutt."

Q. Will you state what sanitary conclusions you draw from the chart just introduced?

A. This chart shows that the Mississippi at Grafton and the Missouri at West Alton contained from January to June, 1900, more albuminoid ammonia and oxygen consumed than the Illinois River at Grafton, that the Desplaines, Kankakee and the Fox contained nearly the same amounts and the Big Vermillion and the Sangamon Rivers at their mouths less amounts. Or, in other words that the Mississippi at Grafton and the Missouri at West Alton contained more undecomposed organic matter than the Illinois at Grafton; that the Kankakee and the Fox contained about the same amounts and the Big Vermillion and the Sangamon less undecomposed organic matter. The free ammonia in all the streams is higher than in the autumn of 1899, but
12135 the relative ratios is not greatly changed, and in the autumn of 1899 as in the spring of 1900 the Illinois at Grafton contained more free ammonia than its tributaries. The nitrogen as nitrites is much less in the Illinois at Grafton in 1900 than in 1899, .027 parts against .047 parts, while the amount in the Mississippi, the Missouri, the Desplaines and the Big Vermillion is about the same in the two different parts of the year.

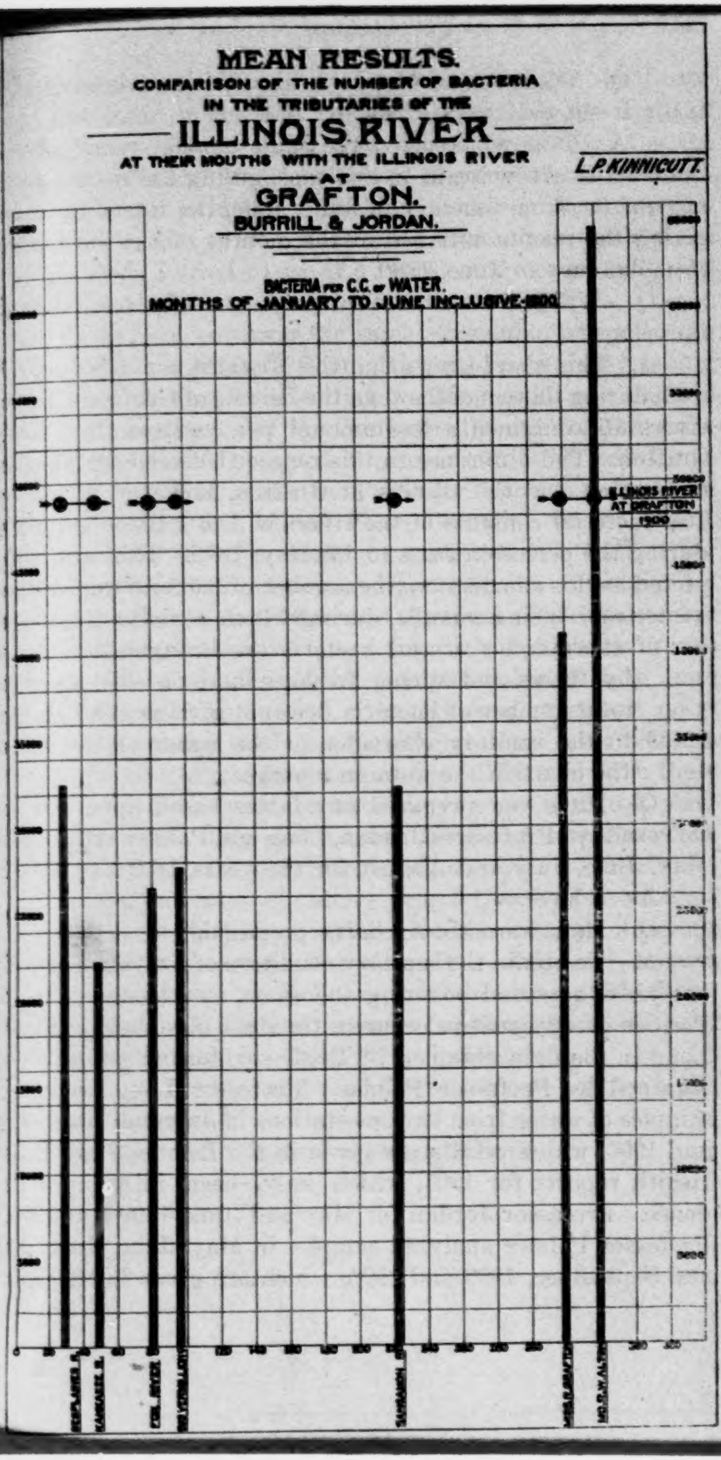
Q. Have you prepared charts comparing the number of bacteria in the tributaries of the Illinois river at their mouths with the Illinois River at Grafton, based upon the bacterial results of Burrill and Jordan for the months of January to June, inclusive, 1900, as they appear in the tables 73 to 80, inclusive, which have just previously been introduced in evidence?

A. I have.

Q. Will you produce the chart and make it a part of your testimony?

A. The chart, with the caption, "Mean results, comparison of the number of bacteria in the tributaries of the Illinois River

at their mouths with the Illinois River at Grafton, Burrill
12136 and Jordan, bacteria per cc. of water for the months of
January to June, inclusive, 1900, L. P. Kinnicutt," is as
follows:



MEAN RESULTS.
COMPARISON OF THE NUMBER OF BACTERIA
IN THE TRIBUTARIES OF THE
ILLINOIS RIVER
AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT
GRAFTON.
BURRILL & JORDAN.

L. P. KINNICUTT.

BACTERIA PER C.C. OF WATER.
MONTHS OF JANUARY TO JUNE INCLUSIVE-1900.

Q. Will you state how this chart is constructed and what
12138 it shows?

A. It is constructed the same as the second preceding chart. The arrow heads in this case, giving the results obtained at Grafton, from January to June, 1900, the top of the columns giving the results obtained at the mouths of the various rivers from January to June, 1900.

Q. Will you state what sanitary conclusions you draw from this chart?

A. This chart shows that the Missouri contained more bacteria during these months than the Illinois at Grafton. The other rivers all contained a less amount per cc. than the Illinois at Grafton. The difference in this respect between the Mississippi at Grafton and the Illinois at Grafton, however, is not great. The bacterial contents of the rivers is 3 to 4 times greater than during the period in June to January, 1899. This was to be expected as this chart shows the number of bacteria during the late winter and spring months, during which period a greater number of saprophytes or soil bacteria are brought into the river by thaws and spring freshets, and on this account the total number of bacteria does not give as good an idea as
12139 to the sanitary character of the water of the rivers as
the chart in the autumn months.

Q. Have you prepared any tables based upon the chemical results of Professors Jordan, Long and Palmer for the months May, June, July and August for the years 1899 and 1900?

A. I have.

Q. How were those charts prepared?

A. To obtain the sanitary condition of a river in two different years a period covering the same months must be taken. Periods of comparison occur in the data obtained by Professor Long in the data obtained by Professor Jordan and in the data obtained by Professor Palmer. Professor Long analyzed the samples of water from various stations in July and August, 1899, and 1900, which results are given in the Illinois State Board of Health reports for 1901, which have been introduced in evidence. Professor Jordan for May and June 1899 and 1900, and Professor Palmer analyzed samples in May, June, July, August and September, 1899 and 1900, which are given in Streams Ex-

amination which have been introduced in evidence. Professor Palmer has made tables and curves representing the state of the river in June, July, August and September, for the
12140 years 1899 and 1900, which set of curves have been introduced in evidence. Wishing, however, to also make a study of the same question, and to include as many analytical data as possible, I tried to see if a table could not be made out including the results obtained by all three observers, Long, Jordan and Palmer, covering the same seasonable period in the two years, 1899 and 1900. I found this could be done by taking the data given by Professor Jordan for May and June, 1899, in Streams Examination, and by Professor Palmer for the same months for 1899, and obtained the mean for May and June, 1899, taking the data given by Professor Long for July and August, 1899, from the Illinois State Board of Health report for 1901, tables 5 to 22, and the data of Professor Palmer for July and August, 1899, in Streams Examinations. I obtained a mean for July and August, 1899, and the mean of the two sets of data thus obtained gave the mean from which changes in the condition of the river during the months of June, July and August, 1899, could be studied. By the same process a mean could be obtained for studying the changes that took place in the months of May, June, July and August, 1900, and from these comparisons could be drawn between the changes that took place in May, June, July and August, 1899, and those that took
12141 place in May, June, July and August, 1900.

In acordance with the above description I have obtained the tables 1 to 24, inclusive, which give the mean of Jordan's Long's and Palmer's results for May, June, July and August, 1899, being tables 1 to 12, inclusive, and the mean of Professor Jordan's, Long's and Palmer's results for May, June, July and August, 1900, being tables 13 to 24, inclusive.

Q. Will you produce and read the tables that you have just described in evidence?

A. Tables 1 to 24, inclusive, are as follows:

12142 TABLE 1.—ILLINOIS RIVER, 1899.

Illinois River.—Joliet, N. of Jackson St., 1899.

Mean of Jördan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	560.0
Soluble Solids	483.5
Suspended Solids	76.5
Total Oxygen Consumed	32.4
Soluble Oxygen Consumed	19.8
Suspended Oxygen Consumed	12.6
Chlorine	86.8
Free Ammonia	12.06
Albuminoid Ammonia	2.34
Nitrogen as Nitrites	.095
Nitrogen as Nitrates	.15
Bacteria per cubic centimeter	1,374,320

Long's I. S. B. H. 1901, Table 5, July 3—August 28.
Jordan's S. E. 1901, Table 84, May 4—June 27.
Palmer's S. E. 1901, Table 4, May 24—June 27 and July 4, August 29.
I. S. B. H.—Illinois State Board of Health.
S. E.—Streams examinations.

12143 TABLE 2.

Illinois River.—Morris, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	420.0
Soluble Solids	390.9
Suspended Solids	29.1
Total Oxygen Consumed	14.6
Soluble Oxygen Consumed	12.1
Suspended Oxygen Consumed	2.5
Chlorine	55.0
Free Ammonia	7.4
Albuminoid Ammonia	0.79
Nitrogen as Nitrites	0.175
Nitrogen as Nitrates	0.5
Bacteria per cubic centimeter	1,136,167

Long's I. S. B. H., 1901, Table 7, July 5—August 29.
Jordan's S. E., 1901, Table 87, June 3—June 27.
Palmer's S. E., 1901, Table 7, May 30—June 24, July 4—August 30.

12144

TABLE 3.

Illinois River.—Ottawa, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	403.9
Soluble Solids	391.5
Suspended Solids	12.4
Total Oxygen Con4umed	12.2
Soluble Oxygen Consumed	11.1
Suspended Oxygen Consumed	1.1
Chlorine	43.5
Free Ammonia	3.1
Albuminoid Ammonia	0.57
Nitrogen as Nitrites	0.65
Nitrogen as Nitrates	1.01
Bacteria per cubic centimeter	19,426

Long's I. S. B. H. 1901, Table 8, July 5—Aug. 29.
Jordan's S. E., 1901, Table 89, June 20—June 27.
Palmer's S. E. 1901, Table 9, June 20—June 27, July 4, Aug. 29.

12145

TABLE 4.

Illinois River.—La Salle, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	420.5
luble Solids	373.8
Suspended Solids	46.7
Total Oxygen Consumed	13.1
Soluble oxygen Consumed	10.5
Suspended Oxygen Consumed	2.6
Chlorine	34.5
Free Ammonia	1.6
Albuminoid Ammonia	0.54
Nitrogen as Nitrites	0.39
Nitrogen as Nitrates	1.61
Bacteria per cubic centimeter	17,388

Long's I. S. B. H. 1901, Table 10, July 13—Aug. 30.
Jordan's S. E. 1901, Table 92, May 25—June 28.
Palmer's S. E., 1901, Table 12, May 6—June 28, July 5—Aug. 30.

12146

TABLE 5.—ILLINOIS RIVER.

Henry, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	425.3
Soluble Solids	372.2
Suspended Solids	53.1
Total Oxygen Consumed	13.0
Soluble Oxygen Consumed	10.5
Suspended Oxygen Consumed	2.5
Chlorine	31.0
Free Ammonia	0.81
Albuminoid Ammonia	0.60
Nitrogen as Nitrites	0.27
Nitrogen as Nitrates	1.16
Bacteria per cubic centimeter	66,189

Long's I. S. B. H. 1901, Table 12, July 10—August 28.
Jordan's S. E., 1901, Table 93, June 1—June 28.
Palmer's S. E., 1901, Table 13, May 31—June 23, July 6—August 30.

12147

TABLE 6.—ILLINOIS RIVER.

Averyville, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	394.0
Soluble Solids	353.8
Suspended Solids	40.2
Total Oxygen Consumed	11.2
Soluble Oxygen Consumed	9.3
Suspended Oxygen Consumed	1.9
Chlorine	25.3
Free Ammonia	0.36
Albuminoid Ammonia	0.67
Nitrogen as Nitrites	0.14
Nitrogen as Nitrates	1.15
Bacteria per cubic centimeter	7,033

Long's I. S. B. H., 1901, Table 13, July 5—August 30.
Jordan's S. E., 1901, Table 94, June 1—June 28.
Palmer's S. E., 1901, Table 14, May, 2—June 28, July 4—August 30.

12148

TABLE 7.—ILLINOIS RIVER.

Wesley City, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	400.0
Soluble Solids	353.9
Suspended Solids	46.1
Total Oxygen Consumed	12.3
Soluble Oxygen Consumed	10.2
Suspended Oxygen Consumed	2.1
Chlorine	24.3
Free Ammonia	0.56
Albuminoid Ammonia	0.72
Nitrogen as Nitrites	0.10
Nitrogen as Nitrates	1.06
Bacteria per cubic centimeter	1,630,877

Long's I. S. B. H., 1901, Table 14, July 5—Aug. 30.
Jordan's S. E., 1901, Table 95, June 1—June 28.
Palmer's S. E., 1901, Table 15, May 31—June 28, July 5—Aug. 30.

12149

TABLE 8.—ILLINOIS RIVER.

Pekin, 1899.

Mean of Jordan's, Long's and Palmer's results, May, June, July and August.

	Parts per million.
Total Solids	399.1
Soluble Solids	356.7
